U. S. DEPARTMENT OF AGRICULTURE.

Scientific Bureaus and Divisions.

- WEATHER BUREAU—Willis L. Moore, *Chief*.
- BUREAU OF ANIMAL INDUSTRY—A. D. Melvin, *Chief*.
- BUREAU OF PLANT INDUSTRY—B. T. Galloway, *Chief*.
- FOREST SERVICE—Gifford Pinchot, *Forester*.
- BUREAU OF SOILS—Milton Whitney, *Chief*.
- BUREAU OF CHEMISTRY—H. W. Wiley, *Chemist*.
- BUREAU OF STATISTICS—V. H. Olmsted, *Statistician*.
- BUREAU OF ENTOMOLOGY—L. O. Howard, *Entomologist*.
- BUREAU OF BIOLOGICAL SURVEY—C. Hart Merriam, *Chief*.
- OFFICE OF PUBLIC ROADS—L. W. Page, *Director*.

OFFICE OF EXPERIMENT STATIONS—A. C. True, *Director*.

THE AGRICULTURAL EXPERIMENT STATIONS.

- ALABAMA—
 - College Station: *Auburn*; J. F. Duggar. ^a
 - Canebrake Station: *Uniontown*; F. D. Stevens. ^a
 - Tuskegee Station: *Tuskegee*; G. W. Carver. ^a
- ALASKA—*Sitka*; C. C. Georgeson. ^b
- ARIZONA—*Tucson*; R. H. Forbes. ^a
- ARKANSAS—*Fayetteville*; W. G. Vineenhellor. ^a
- CALIFORNIA—*Berkeley*; E. J. Wickson. ^a
- COLORADO—*Fort Collins*; L. G. Carpenter. ^a
- CONNECTICUT—
 - State Station: *New Haven*; E. H. Jenkins. ^a
 - Storrs Station: *Storrs*; L. A. Clinton. ^a
- DELAWARE—*Newark*; H. Hayward. ^a
- FLORIDA—*Gainesville*; P. H. Rolfs. ^a
- GEORGIA—*Experiment*; Martin V. Calvin. ^a
- HAWAII—
 - Federal Station: *Honolulu*; J. G. Smith. ^b
 - Sugar Planters' Station: *Honolulu*; C. F. Eckart. ^a
- IDAHO—*Moscow*; H. T. French. ^a
- ILLINOIS—*Urbana*; E. Davenport. ^a
- INDIANA—*Lafayette*; A. Goss. ^a
- IOWA—*Ames*; C. F. Curtiss. ^a
- KANSAS—*Manhattan*; C. W. Burkett. ^a
- KENTUCKY—*Lexington*; M. A. Scovell. ^a
- LOUISIANA—
 - State Station: *Baton Rouge*;
 - Sugar Station: *Audubon Park, New Orleans*;
 - North La. Station: *Calhoun*;
- MAINE—*Orono*; C. D. Woods. ^a
- MARYLAND—*College Park*; H. J. Patterson. ^a
- MASSACHUSETTS—*Amherst*; W. P. Brooks. ^a
- MICHIGAN—*East Lansing*; C. D. Smith. ^a
- MINNESOTA—*St. Anthony Park, St. Paul*; E. W. Randall. ^a

- MISSISSIPPI—*Agricultural College*; W. L. Hutchinson. ^a
- MISSOURI—
 - College Station: *Columbia*; H. J. Waters. ^a
 - Fruit Station: *Mountain Grove*; Paul Evans. ^a
- MONTANA—*Bozeman*; F. B. Linfield. ^a
- NEBRASKA—*Lincoln*; E. A. Burnett. ^a
- NEVADA—*Reno*; J. E. Stubbs. ^a
- NEW HAMPSHIRE—*Durham*; E. D. Sanderson. ^a
- NEW JERSEY—*New Brunswick*; E. B. Voorhees. ^a
- NEW MEXICO—*Agricultural College*; Luther Foster. ^a
- NEW YORK—
 - State Station: *Geneva*; W. H. Jordan. ^a
 - Cornell Station: *Ithaca*; L. H. Bailey. ^a
- NORTH CAROLINA—
 - College Station: *West Raleigh*; C. B. Williams. ^a
 - State Station: *Raleigh*; B. W. Kilgore. ^a
- NORTH DAKOTA—*Agricultural College*; J. H. Worst. ^a
- OHIO—*Wooster*; C. E. Thorne. ^a
- OKLAHOMA—*Stillwater*; W. L. English. ^a
- OREGON—*Corvallis*; J. Withycombe. ^a
- PENNSYLVANIA—*State College*; T. F. Hunt. ^a
- PORTO RICO—*Mayaguez*; D. W. May. ^b
- RHODE ISLAND—*Kingston*; H. J. Wheeler. ^a
- SOUTH CAROLINA—*Clemson College*; J. N. Harper. ^a
- SOUTH DAKOTA—*Brookings*; J. W. Wilson. ^a
- TENNESSEE—*Knoxville*; H. A. Morgan. ^a
- TEXAS—*College Station*; H. H. Harrington. ^a
- UTAH—*Logan*; E. D. Ball. ^a
- VERMONT—*Burlington*; J. L. Hills. ^a
- VIRGINIA—*Blacksburg*; —
- WASHINGTON—*Pullman*; R. W. Thatcher. ^a
- WEST VIRGINIA—*Morgantown*; J. H. Stewart. ^a
- WISCONSIN—*Madison*; H. L. Russell. ^a
- WYOMING—*Laramie*; J. D. Towar. ^a

^a Director.

^b Special agent in charge.

EXPERIMENT STATION RECORD.

Editor: E. W. ALLEN, Ph. D., *Assistant Director.*

EDITORIAL DEPARTMENTS.

- Meteorology, Soils, and Fertilizers—W. H. BEAL.
Agricultural Botany and Vegetable Pathology—W. H. EVANS, Ph. D.
Field Crops—J. I. SCHULTE.
Horticulture and Forestry—E. J. GLASSON.
Zootechny and Human Nutrition—C. F. LANGWORTHY, Ph. D.
Agrotechny, Dairy Farming, and Dairying—H. W. LAWSON.
Agricultural Chemistry—W. H. BEAL, C. F. LANGWORTHY, and H. W. LAWSON.
Economic Zoology, Entomology, and Veterinary Medicine—E. V. WILCOX, Ph. D.
Rural Engineering—B. P. FLEMING.
Rural Economics—J. B. MORMAN.
Agricultural Education—D. J. CROSBY.

EDITORIAL NOTES.

	Page.
The individual as a factor in agricultural research.....	1
The scarcity of men for investigation.....	3
The investigator and his salary.....	5
James J. Hill upon the future of American agriculture.....	101
Problems for investigation on soil fertility.....	103
Progress in medical and in agricultural science and practice.....	201
Relation between investigation and instruction.....	204
Retirement of Director R. J. Redding.....	206
Attitude of the experiment stations toward agricultural research.....	301
"The kind and character of work under the Adams Act".....	303
Development of public sentiment for agricultural investigation.....	304
Extension teaching in agriculture.....	401
Organization of extension work.....	403
Some problems in agricultural instruction.....	501
The training of teachers for agricultural instruction.....	503
Department of nutrition in the Carnegie Institution.....	505
The American Breeders' Association.....	601
Scientific aspect of plant-breeding work.....	602
The retirement of Dean W. A. Henry.....	605
The agricultural appropriation act, 1907-8.....	701
Increased Federal aid to agricultural education.....	705
M. Berthelot, deceased.....	705
The Adams fund projects and what they show.....	801
Advantages of systematizing station work.....	806
Robert Warington, deceased.....	807
Semicentennial of the Michigan Agricultural College.....	901
Significance of the agricultural college in the development of American education.....	902
A broad conception of agricultural education.....	906

	Page.
The present need of men in agricultural research.....	1001
Agricultural research as a career.....	1003
The training of investigators in agriculture.....	1004
Retirement of Dr. C. A. Goessmann.....	1101
The life of the soil.....	1104

SPECIAL ARTICLES.

Convention of Association of American Agricultural Colleges and Experiment Stations, E. W. Allen.....	406
Problems of animal nutrition, Henry Prentiss Armsby, Ph. D.....	508
Convention of Association of American Agricultural Colleges and Experiment Stations, 1907, E. W. Allen.....	1007

STATION PUBLICATIONS ABSTRACTED.

ALABAMA COLLEGE STATION:

Bulletin 135, June, 1906.....	245
136, August, 1906.....	680
137, September, 1906.....	547
138, December, 1906.....	828, 829

EDITORIAL DEPARTMENTS.

Meteorology, Soils, and Fertilizers—W. H. BEAL.
Agricultural Botany and Vegetable Pathology—W. H. EVANS, Ph. D.
Field Crops—J. I. SCHULTE.
Horticulture and Forestry—C. B. SMITH.
Zootechny and Human Nutrition—C. F. LANGWORTHY, Ph. D.
Agrotechny, Dairy Farming, and Dairying—H. W. LAWSON.
Agricultural Chemistry—W. H. BEAL, C. F. LANGWORTHY, and H. W. LAWSON.
Economic Zoology, Entomology, and Veterinary Medicine—E. V. WILCOX, Ph. D.
Rural Engineering—B. P. FLEMING.
Rural Economics—J. B. MORMAN.
Agricultural Education—D. J. CROSBY.

CONTENTS OF VOL. XVIII, NO. 1.

Editorial notes:	Page.
The individual as a factor in agricultural research.....	1
The scarcity of men for investigation	3
The investigator and his salary.....	5
Recent work in agricultural science.....	7
Notes.....	94

SUBJECT LIST OF ABSTRACTS.

AGRICULTURAL CHEMISTRY.

Free acids in mineral and bone superphosphates, Quartaroli and Masoni	7
Free acid in superphosphate, Schucht.....	7
Determination of nitrates in presence of nitrites, Busch	7
Examination of water, Mason	7
The determination of nitric acid in water, Drawe	7
Modern methods of testing milk and milk products, Van Slyke	7
On the oxidation index of milk, Comanducci.....	8
Note on paper by Steinegger on "aldehyde figure," Richmond and Miller.....	8
The estimation of fat in homogenized milk, Richmond.....	8
The analysis of dried milk, Richmond.....	8
Determination of the proteids in milk, Trillat and Sauton.....	9
Estimation of casein. A preliminary study, Army and Pratt	9
The determination of fat in cheese, Weibull.....	9
Chemistry in the kitchen and household, Abel	9
Chemical department, Ladd.....	9
Report of the chemist, Hare	9
Laboratory of Swedish Royal Agricultural Academy, 1856-1906, Söderbaum.....	10
Report of chemical control station at Trondhjem, 1905, Solberg.....	10

METEOROLOGY—WATER.

	Page.
Practical treatise on the weather, Freybe	10
Instructions for cooperative observers	10
Summaries of temperatures, rainfall, sunshine, and evaporation, Ladd	10
Studies on diurnal periods in lower strata of the atmosphere, Bigelow	10
Meteorological service for forecasting weather, Dufour	10
Meteorology of Tunis, winter of 1905-6, Ginestous	10
Contribution to the study of spring and fall frosts, Vanderlinden	11
Balloons and kites in the service of meteorology, Dines	11
Recent practice in the erection of lightning conductors, Henry	11

The purification of sewage, Ramsay	12

SOILS—FERTILIZERS.

Rock weathering and soil formation in arid and humid regions, Hilgard	12
On the changes which minerals undergo in cultivated soils, Biéler	12
Wire-basket method for determining manurial requirements of soils, Gardner ..	12
Soil analysis and agricultural charts in Italy, Fascetti	13
The soils of Victoria, Cherry	13
Notes on physical properties of soils of the Ganges Valley, Leake	13
Banana soils of St. Mary and Upper St. Catherine [Jamaica], Cousins	13
The lime content of some esparcet soils, Stebler	14
Regeneration of overlimed soil, Maki and Tanaka	14
On the formation of humus, Suzuki	14
Plant nutrition studies, Voorhees and Lipman	14
Measure of soil fertility from the nitrogen standpoint, Lipman	15
Variations in nitrogen content of bare soils, Warmbold	16
Work of Agricultural-Bacteriological Institute of Göttingen University, Koch ..	16
On the question whether nitrates or nitrates are produced by non-bacterial processes in the soil, Russell and Smith	17
Fixation of atmospheric nitrogen during decomposition, Montemartini	18
Investigations on the use of nitrogenous materials, Voorhees and Lipman	18
Direct utilization of nitrogen of air for fertilizers, etc., Frank	18
Fertilizer tests of lime nitrogen and nitrate of soda on oats, Otto	18
Calcium cyanamid and nitrate, and results of their use, von Feilitzen	19
New nitrogenous manure, lime nitrogen or calcium cyanamid, Hendrick	19
Experiments with lime nitrogen as fertilizer for sugar beets, Strohmer	19
Experiments on the action of nitrogen lime, Bötcher	19
Lime nitrogen, Sjøllema	19
Results of experiments with calcium cyanamid (lime nitrogen), Pozzoli	19
Factors which influence decomposition of calcium cyanamid, Stoklasa	19
Vegetation experiments with "N" fertilizer in 1905, von Lepel	20
Green manuring experiments in 1905, Baessler	20
Experiments with fertilizers, Stewart and Atwood	20
Results of cooperative experiments with fertilizers on swamp soils, Harcourt ..	21
Tests of Peruvian guano and ammoniated superphosphate 9:9, Arnstadt	21
The action of ammoniacal nitrogen as a fertilizer, Pfeiffer	21
Use of commercial nitrogen in connection with barnyard manure, Bachmann ..	21
The use of waste organic substances as manures, Russell	21
Action of phosphoric acid on higher plants, von der Crone	21
On phosphoric acid of ashes, Prianishnikov	22
Analysis of deposits of calcium phosphate in the United States, Jumeau	22
The utilization of sugar-beet slump by the Dessau method, Ost	22
History of the fertilizer industry, Ruhm, jr.	22
The chemical fertilizer industry, Schucht	22
Commercial fertilizers, Goss and Jones, jr.	22
Analyses of commercial fertilizers, Scovell et al.	23
Analyses and valuations of fertilizers, Street, Allen, and Carberry	23
Fertilizer analyses, fall season, 1905, and spring season, 1906, Kilgore	23
Analyses of commercial fertilizers	23

	Page.
Standard fertilizers, 1906, Macfarlane.....	23
Fertilizers, Voelcker.....	23
Use of chemical fertilizers in Belgium during 1895-1905, Berger.....	23
Production and commerce in basic slags in Belgium.....	23

AGRICULTURAL BOTANY.

Agricultural botany, Schribaux and Nanot.....	24
Native economic plants of Montana, Blankinship.....	24
Report of the botanist, Bolley.....	24
Germination of seeds of the castor-oil plant, Green and Jackson.....	24
On stimulants of nutrition in plants, Mischeels.....	25
Nature of galvanotropic irritability of roots, Ewart and Bayliss.....	25
Action of organic substances on form and structure of leaves, Molliard.....	25
Growth of plants in amids in absence of carbon dioxide, Lefèvre.....	26
On the water relations of the cocoanut palm, Copeland.....	26

FIELD CROPS.

Results of cooperative experiments in agriculture, Zavitz.....	27
The Woburn field experiments, 1904, Voelcker.....	28
The Woburn pot-culture experiments, 1904, Voelcker.....	28
[Report on the] subsection of agronomy, Olin.....	28
Report of the agriculturist, Vernon.....	29
[Report on field crops], Sheppard.....	29
Forage crops, 1905, Billings.....	30
Observations and experiments on clover, alfalfa, and soy beans, Garman.....	31
Culture tests in 1904 and 1905, Danseaux.....	31
Manurial value of different potassium compounds for barley and rice, Aso.....	32
Influence of reaction of manure upon yield, Aso and Bahadur.....	32
On the lime factor for flax and spinach, Namikawa.....	32
Plowing experiments, Farrer and Sutton.....	32
Alfalfa, Headden.....	32
Alfalfa, Headden.....	33
The alfalfa seed crop and seeding alfalfa, Ten Eyck.....	33
Alfalaria (<i>Erodium cicutarium</i>) as a forage plant in Arizona, Thornber.....	33

The principal insects attacking the cocoanut palm, H, Banks.....	60
Moth borer in sugar cane, maize, and sorghum, Maxwell-Lefroy.....	60
The melon fly, Van Dine.....	61
Codling moth parasites, Froggatt.....	61
The Brazil fruit fly parasites, Lounsbury.....	61
The grape curculio, Brooks.....	61
Arsenical treatment of grape flea beetles, Trabut.....	62
The Bombay locust (<i>Acridium succinctum</i>), Maxwell-Lefroy.....	62
A hopperdozer, Blinn.....	62
A new book and leather pest, Kotinsky.....	63
Deposition of the eggs and larvæ of <i>Estrus oris</i> , Collinge.....	63
Life history of ox warble flies <i>Hypoderma bovis</i> and <i>H. lineata</i> , Imms.....	63
Rôle played by biting flies in the spread of trypanosomiasis, Holmes.....	63
The anatomy and physiology of the tsetse fly, Stuhlmann.....	63
Action of <i>Aspergillus niger</i> and <i>A. glaucus</i> on the larvæ of <i>Culex</i> and <i>Anopheles</i> , Galli-Valerio and Rochaz-de-Jongh.....	64
Bordeaux mixture and Paris green, Sherman, jr., and Woglum.....	64
Annual report of Beekeepers' Association of the Province of Ontario, 1905.....	64
Note on bacteria pathogenic to the silkworm, Sawamura.....	64

FOODS—HUMAN NUTRITION.

Cooking quality of potatoes.....	65
The cooking of starches in cereals, Mulberry.....	65
Preservation of foods on a commercial scale, Rocques.....	65

	Page.
A practical guide to cookery in West Africa and the Tropics, Cockburn.....	65
Food analyses, Juritz.....	65
Adulteration of food, Gerald.....	66
Elements of applied microscopy, Winslow.....	66
The testing of yeast employed in bread making.....	66
Decomposition of French mustard by bacteria and its prevention, Kossowicz.....	66
A study of three vegetarian diets, Paton and Dunlop.....	66
Results of digestion experiments with milk powder, Krull.....	67
Nitrogenous metabolism in normal individuals, Hamill and Schryver.....	67
Carbohydrate combustion in the animal body, Stoklasa.....	67
Chemistry of digestion. III, Proteid cleavage, London.....	67
Extractive material of muscular tissue. III, Methylguanidin, Gulewitsch.....	67
Protein assimilation in the animal body, Abderhalden and Rona.....	67
A law of growth reiterated, Lusk.....	67
Demands for heat and calorimetric value of a ration, Lefèvre.....	68
The body's utilization of fat, Mathews.....	68
The right method of eating, Einhorn.....	68
Vegetable products in feces, Netolitzky.....	68

ANIMAL PRODUCTION.

Nutritive value of several kinds of hay, Tangl and Weiser.....	68
The nutritive value of dried wine lees, Weiser.....	68
Composition and feeding value of cucurbits, Zaitschek.....	69
The nutritive value of ground beech bark, Zaitschek.....	69
Proposed act relative to sale of concentrated feeding stuffs, Gamble.....	69
Fattening cattle for the years 1904 and 1905, Linfield.....	69
Feeding range steers, Vernon.....	70
The quantity of milk taken by nursing calves, Henkel and Mühlbach.....	70
Sheep feeding experiments for the years 1904-5, Linfield.....	70
Experiments with crossbred sheep at Glen Innes Experimental Farm.....	71
Effect of covering the body on distribution of fat, Bergonié.....	71
Pig feeding experiments, Linfield.....	71
Digester tankage for swine, Shaw.....	72
Motion and muscular work in relation to digestion in horses, Scheuert.....	73
The Ranidæ: How to breed, feed, and raise the edible frog.....	73
Studies in oyster propagation, Nelson.....	73
First lessons in poultry keeping, Robinson.....	73
Poultry work for 1905, Shepperd.....	73
The American standard of perfection.....	73
The production of brown or tinted eggs.....	74
Egg production of virgin fowls, Nelson.....	74

DAIRY FARMING—DAIRYING.

Feeding experiments, Billings.....	74
Experiments with the dairy herd, Billings.....	74
Dairying, Vernon.....	74
Tests of Guernsey cows for advanced registry.....	74
Milking trials.....	75
Growth and activity of mammary glands, Lane-Clayton and Starling.....	75
Elimination of nitrates by the mammary gland, Marcas and Huyge.....	75
On the bacteriological conditions of the udder and the milk, Barthel.....	75
Bitter milk, Huyge.....	75
Spontaneous heat production in milk and lactic fermentation, Rubner.....	75
The action of formalin and hydrogen peroxid in milk, Bandini.....	75
On the addition of foreign fats to milk, Girard.....	76
Grading cream, Erf.....	76
A new Babcock milk-testing bottle, Whitman.....	76
Examination of Babcock test apparatus.....	76
Manufacture and storage of butter. I, Keeping qualities, Gray and McKay.....	76
Yields of salted and unsalted butter, Friis.....	77
Denmark's butter exports, 1904-5, Bøggild.....	77
The cold storage of cheese, Lane.....	77

	Page.
Cold curing of American cheese, Doane	78
The manufacture of Lancashire cheese, Lloyd	78
Lactic-acid bacteria in curd and cheese of Cheddar type, Harrison	79
Composition of cheese consumed in France, Lindet, Aumann, and Brugière	79
Investigations on the ripening of cheese, Cornalba	79
A handbook for test associations, Hansson	79
A handbook for members of test associations, Gripenberg	79
Profitable dairy farming, Hansson	79

VETERINARY MEDICINE.

Annual report on pathogenic micro-organisms, Von Baumgarten and Tangl ..	80
Collected studies on immunity, Ehrlich, trans. by Bolduan	80
Local treatment of parasitic and infectious diseases, Bernardini	80
Public abattoirs. I, Construction and arrangement, De Loverdo	80
Public abattoirs. II, Inspection and administration, Martel	80
Report of the veterinarian, Glover	81
Eradication of tuberculosis by the methods of Bang and Ostertag, Richter	81
Milk artificially infected with tubercle bacilli, Schroeder and Cotton	82
Behavior of the cows' udder toward infection with tubercle bacilli, Meyer	82
Tuberculosis of the male genital organs of cattle, Kowalewsky	83
Tuberculin tests, Nielsen	83
Tuberculin and the organism, Köhler	83
Demonstration of antituberculin and tuberculous tissue, Weil and Nakajama ..	83
The leucocyte and the tubercle bacillus, Bartel and Neumann	83
A special method for cultivating tubercle bacillus on potatoes, Anzilotti	84
The tubercle bacillus cultivated in a saccharine medium, Vailliant	84
A method for demonstrating anthrax bacilli in blood and tissues, Forster	84
Protozoan blood diseases of man and animals in German East Africa, Reutlein ..	84
Ticks and African coast fever, Lounsbury	84
Tissue alterations in udder in sporadic galactophoritis, Van der Linde	84
A disease of young cattle in county Wexford, Mettam	85
Proliferation of connective tissue in beef liver in distomatosis, Jaeger	85
A hoof disease occurring in connection with foot-and-mouth disease, Schenkl ..	85
Louping ill and braxy, Hamilton et al.	85
Diseases of swine, Craig	86
The hog cholera group of bacteria, Citron	86
Immunization of hogs against swine plague by means of aggressin, Weil	86
Intestinal emphysema of hogs, Jaeger	86
Treatment of tetanus, Desoubry	87
Trypanosomiasis of horses in Annam, Vassal	87
Horse botflies and their importance in raising colts, Kröning	87
The army horseshoer, Dowd et al.	87
The rapid diagnosis of rabies, Frothingham	87
The significance of Negri's corpuscles in the diagnosis of rabies, Ernst	88
Negri's corpuscles in rabies, Ball	88
The toxin produced by <i>Aspergillus fumigatus</i> , Bodin and Gautier	88
The forms of chicken pox and their relation to true pox, Reischauer	88
Cachexia due to <i>Syngamus trachealis</i> in pigeons, Rossi	89

RURAL ENGINEERING.

Interstate royal commission on the River Murray	89
Suggestions for construction of small pumping plants for irrigation, Newell ..	90
Agricultural machinery in the United States	90
Test of American manure-spreading machine	90
Two tools for the culture of root crops	90
Plowing by electricity at Dahlwitz	91
The windmill in agriculture, Lawford	91
Utilization of solar heat for industrial purposes, Güntner	91
Tests of the relative value of crude oil, kerosene, and gasoline	91

RURAL ECONOMICS.

Rural economy, Lanman	91
The transition in agriculture, Pratt	92

	Page.
Crop Reporter.....	92
Cotton production and cotton-seed products, 1905, Stenart and Roper.....	92
Virginia, its forests, minerals, and agricultural possibilities, Willey.....	93
How to keep farm accounts, Steiner.....	93
Farm accounts, Vye.....	93

MISCELLANEOUS.

Eighteenth Annual Report of Colorado Station, 1905.....	93
Publications of Colorado Station, 1903-4.....	93
Annual Report of Florida Station, 1905.....	93
Annual Report of New Jersey Stations, 1905.....	93
Fifteenth Annual Report of New Mexico Station, 1904.....	93
Sixteenth Annual Report of North Dakota Station, 1905.....	93
Work of the Plot Experiment Station, 1895-1904, Bichikhin et al.....	93

LIST OF EXPERIMENT STATION AND DEPARTMENT PUBLICATIONS REVIEWED.

Stations in the United States.

	Page.		Page.
Arizona Station:		Michigan Station:

Bureau of Plant Industry:		Doc. 344.....	10
Bul. 93.....	53	Doc. 347.....	10
Bul. 100, pt. 1 (5 cents).....	54		

NOTE.—The publications of the United States Department of Agriculture, except those of the Weather Bureau, may be purchased from the Superintendent of Documents, Washington, D. C. For the publications of the Weather Bureau, requests and remittances should be directed to the Chief of the Bureau. The price of the Record is \$1 per volume, or 10 cents per number. The prices of other technical publications are given in the list above. The publications of the State experiment stations are distributed from the stations and not from the Department.

EXPERIMENT STATION RECORD.

VOL. XVIII.

SEPTEMBER, 1906.

No. 1.

In all lines of investigation the individual is the all-important and determining factor. Buildings, equipment, the scientific atmosphere, and the inspiration of the field all contribute to make the conditions favorable and to stimulate activity; but without the genius and originality of the man himself the progress along original lines will be slow and uncertain. Upon him will depend in very large measure the character and the success of the investigation.

In agriculture this is especially the case. Agricultural research calls for very special qualifications in the way of native ability and scientific acumen. It requires as high order of training and experience as any line of research in either pure or applied science, and in addition it demands a general knowledge of practical methods and conditions in order that the investigation may be directed intelligently. It represents the culmination of efforts for the advancement of agriculture upon an enlightened and scientific basis, and as such it should have the very best material available, surrounded by conditions which will be conducive to the best results. More depends upon it for the progress of the human race than upon research in any other line of industry.

The problems in agriculture are complex, requiring a deep insight and the ability to separate them into their various phases. The investigator should have a sufficient grasp of the subject in both its practical and its scientific relations to be able to analyze it and determine the point of attack. This implies thorough familiarity with the methods of research, the ability to concentrate upon some phase and to make progress on the basis of definite knowledge. For scientific study the projects must not be too broad or include too many factors of possible influence. They must be simplified so as to bring them down to a working basis, and gradually as one point after another is cleared up, they can be broadened and extended.

The difficulty which some men have in outlining a project definitely, so that it may be considered by itself as a definite phase instead of as a broad problem, is in part due to insufficient training for research. Too few of our station men have had the advanced train-

ing which this requires. It is not acquired in the regular college course. It comes with special study under a trained mind, in the course of which something of the spirit of investigation is imbibed, the meaning of an investigation is learned, and familiarity is gained with the methods of procedure. Unless a man has had this or its equivalent, it is too much to expect that he can fully appreciate the real differences between research which gives definite knowledge, and more superficial experiments which give results only half understood, or that he can differentiate his subject and outline a scientific method of procedure.

Station men divide themselves into three general classes, all useful in the advancement of agriculture, but with special qualifications which should be recognized in organizing the work. There is the man in especially close touch and sympathy with the farmer, who is impressed with the need of disseminating information upon matters already known, and whose greatest interest and success lies along the line of demonstration experiments and extension work—a promoter as it were, who by the force of his enthusiasm and his ability to present matters in a convincing way has great influence in introducing improved methods and in spreading the work of the station. This is essentially extension work. It depends upon the work of others, and lacks originality except in interpretation and application. Such men are not suited temperamentally to the work of investigation, but they may be able to make better use of the results than the investigator himself.

Another class of men conduct trials and experiments upon a great variety of practical questions in farm management, using rather simple, conventional methods, and often carrying the work out upon a commercial scale. A considerable amount of scientific data may be collected in their work, but this is reported in a somewhat incidental manner, and is not digested and marshalled in such a way as to contribute to a scientific understanding of the results observed or the principles involved. The real object is to show the most economical method of fertilizing for a given crop, the comparative value of this and that feeding stuff, the yield returned under different methods of culture, and the like.

A third group of men always have in mind, even in what are apparently simple experiments, a recognition of the principles which are operative and which serve to explain the results. They so plan their work as to not only give the farmer a practical answer, but to answer the questions of science as well. They are not satisfied with the empirical result. The spirit of the investigator demands to know why, and they will not be satisfied until they have worked out the fundamental reason.

The last class unfortunately makes up the smaller number. The gap between them and the second class is often a narrow one, and shows itself chiefly in an attitude of mind. Their work often does not appeal as strongly to the popular mind, and arouses little interest until some brilliant result is secured. It is not spectacular in character, and there is greater difficulty in securing appropriations for it. It was largely for this reason that Congress was asked to provide the means for extending it through a permanent appropriation.

The scarcity of men suited to the advanced work contemplated by the Adams Act is the principal cause of difficulty experienced in preparing for operations under that act. It represents a certain unreadiness in some instances.

This scarcity is to a large degree a result of the ideals and tendencies which have dominated station work in the past. The practical phase—the immediately practical phase—has been constantly in the foreground. The earlier years of the stations' existence were given to winning the farmer's confidence and support by doing work which would appeal directly to his practical sense, and since then we have been busy trying to answer, usually in the quickest way, the questions he has showered upon us. There has been an increasing demand for such work, and there has grown up a too prevalent idea that, as the stations belong to the farmers, their duty is to serve the farmer in his own way. In our desire to recognize him we have gone to the extreme in some respects, and it has affected our progress as scientific institutions. It has done more; it has affected our standards of ourselves and of our own requirements. It has given false ideals to young men preparing to enter the work, and insufficient encouragement to those who have striven to give their work a deeper trend. Too often the measure of a man's success has seemed to be his ability to get at the farmers, and to do some comparatively simple work which attracted popular attention. The standard for station workers has been too low. This has already had its effect, which is now being keenly felt in a lack of the true spirit of investigation and a scarcity of men suited to undertake it.

There is no question as to the ultimate aim of the stations, or the desirability of doing work which will be of assistance to the farmer. The station is for the benefit of the farmers as a body—for agriculture; but it is a mistake to encourage the impression that the station is a question box, and to make the immediately practical experiment the only goal of our ambition. There is little danger at our American stations that the practical needs of the farmer will not be kept prominently in mind; but with the progress of our work year by year there is great need of broader and deeper study of the problems we are passing upon, to reduce the empirical results to a more scientific foundation and furnish a safer basis for generalizations.

The planning and inauguration of work under the Adams Act will require careful gauging of the abilities of different members of the station staff, in order to select those best suited to undertake investigations. It must recognize the advanced character of the work to be undertaken and the special qualifications of the individuals composing the staff.

At many of the stations there is a quite general demand from the different departments for a share of the new fund to supplement their resources, and the easiest method is naturally to divide it between the different departments of the station without a very critical consideration of the proposed work. This will not meet the requirements, and will surely not yield the best results. It will include work which does not belong under that fund, and it will usually provide too many projects, reducing the means available for each so that it will be impossible to do the thorough work which is contemplated. The projects need to be very carefully sifted, and those selected which commend themselves especially by reason of their character, their ultimate importance, and the facilities of the station.

In every station there are some men and some departments better fitted to this higher work than others. In every case a process of selection or elimination must be followed, and in some cases men must be secured from the outside to plan and conduct the new lines of investigation. At best only a few men in each station should be selected at the outset.

Not only does the new work raise the grade of requirements in the personnel, but it calls for a differentiation in the station work as a whole—for greater concentration upon investigation as distinguished from other duties. Obviously a man engaged in such work should not be hindered and burdened by elementary teaching or farmers' institute work or answering miscellaneous correspondence or supervising control or police work. The college and station work should be so organized as to free him from such interruptions and distractions, except on special occasions. Other men can attend to these various duties, but the man with the genius for investigation is too rare to be sacrificed to the duties more easily provided for.

Already there has been considerable demand for new men with good scientific education and capable of advanced work—usually for men who have developed as experts in special lines. This will result in a shifting of men from one institution to another, and the keen competition for the men of established reputation will doubtless result in many of the institutions with smaller revenues losing their most valuable men to the larger and more favored ones. This shifting is a very serious matter, often resulting in much waste of time and funds in incomplete investigations. Time is required for becoming familiar with new conditions and for establishing the work in a

new locality. On the other hand, much time is lost to the station in finding and training another man, and the efficiency of the station in that line is temporarily diminished. There is no saving in exchanging a man of known ability and usefulness for one a few hundred dollars cheaper who is an uncertain quantity and must learn the conditions and adjust himself. On the contrary, there is a period of unproductiveness and uncertainty which is expensive to the station and an added strain on the administration.

These changes in personnel might often be avoided by a fuller recognition of the relative value of the man to the station, and a breaking away from tradition or uniformity in the matter of salary. This should be appreciated by those responsible for the stations' welfare. Any station which has a man with a real genius for investigation in the lines it proposes to pursue should make every effort to retain him, even at the sacrifice of precedent. Given a similar line of problems, an investigator of recognized ability is usually as valuable to the station where he is as to another. The Adams fund has tended toward an equalization of the stations in the matter of investigation. The burden of such work rests upon all alike. Each station now has a special research fund of \$7,000 this year, which will go on increasing for the next four years, when it will represent an endowment of \$300,000 at 5 per cent. This is a very creditable research fund for any institution, and should enable the payment of salaries which will insure the best men the field affords.

At a considerable number of institutions the scale of salaries is too low to expect the most competent men to remain. The lesson this false economy has taught should have left its impression long ago. Cheap men are always expensive if of indifferent ability, especially in the advanced work of investigation, and if their work is stamped with high ability they are soon called to other positions. Better far to pay a good salary which will keep men satisfied and assure a certain degree of permanency than to lower the grade of efficiency by frequent changes or employing men of second-rate ability.

The station work should not be held down by a low salary standard in the college or university, as is sometimes the case at present. This is an unfortunate policy and fails to recognize three things—the relative scarcity of men of high attainments in agricultural science, the expert character of the service required, and the longer period of the working year in the station than in the instruction departments. Good business judgment must recognize that the supply of men who have specialized in agricultural science and won distinction as investigators is considerably short of the demand. In other walks of life a man's earning capacity is gauged by his ability and the supply of equally able men. There is no reason why this should not hold in

the station work, especially in the advanced work where the highest order of ability is required. Too great conservatism in the matter of salary will surely prevent the expectations of the Adams Act from being fully realized, by keeping down the grade of men who enter and continue in this work, and by causing the better ones to be drawn away to stations which bid higher.

More young men should be encouraged to enter experiment station work and to take advanced courses which will give them a thorough grounding and make them strong and resourceful investigators. A large number of such men are needed in nearly every department of agricultural work to-day. Surely there should be encouragement for men with a taste for research to prepare themselves for it along agricultural lines. A career is open to them which is attractive from the fullness of the field and the opportunity for great public usefulness. The pecuniary rewards are not such as may be reached in commercial lines, although there the higher salaries are actually reached by only the few. But such work is inviting to men with a taste for it, aside from the mere matter of salary, and in no line of research is a more inspiring field open. The high grade of the service should be fully recognized in both the dignity of the position and the salary. Competent recruits are needed now more than ever before in the history of our stations. They are essential to the development of their work and to meeting the requirements and expectations of the Adams Act.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY.

On the free acids in mineral and bone superphosphates, A. QUARTAROLI and G. MASONI (*Staz. Sper. Agr. Ital.*, 38 (1905), No. 5-6, pp. 492-502; *abs. in Chem. Centbl.*, 1905, II, No. 13, pp. 984, 985).—To determine free acids the authors shake up 25 gm. of material with 250 cc. of water for a few minutes, filter quickly through a folded filter, and titrate 50 cc. of the filtrate diluted to 300 cc. with one-half normal sodium hydroxid and methyl orange. Of 100 mineral superphosphates thus examined the majority contained from 5.29 to 10.98 per cent of free acids reckoned as phosphoric acid, a few contained as low as 2.6 per cent. The bone superphosphates seldom contained over 2.5 per cent of free acids. The presence of larger amounts, 5 to 6 per cent, indicated adulteration with mineral superphosphate. To further aid in the detection of adulteration the authors determined the constants for inversion of saccharose by the two superphosphates, by phosphoric acid, and by sulphuric acid, by treating 1 gm. of pure saccharose for 6 to 12 hours at 25° C. with 30 cc. of thirtieth-normal solution of these substances and determining the inverted sugar by the Fehling method. These constants, with the results of the titration for free acid and of a physical examination, are thought to furnish reliable means of detection of adulteration of bone superphosphate by mineral superphosphate.

Free acid in superphosphate, L. SCHUCHT (*Ztschr. Angew. Chem.*, 18 (1905), pp. 1020-1023; *abs. in Jour. Chem. Soc. [London]*, 88 (1905), No. 515, II, p. 619).—Five gm. of the superphosphate is extracted 10 times with acetone, using in all about 75 cc. of the solvent. The turbid solution obtained is cleared up with 200 cc. of water, a little sodium oxalate and sodium chlorid are added, the solution filtered if necessary, and the free acid is titrated with half-normal alkali, using methyl orange as indicator.

The oxidation of nitrous acid by means of hydrogen peroxid; determination of nitrates in presence of nitrites, M. BUSCH (*Ber. Deut. Chem. Gesell.*, 39 (1906), No. 6, pp. 1401-1403; *abs. in Chem. Centbl.*, 1906, I, No. 21, p. 1675).—The author found in experiments with nitro-cellulose that the use of a 3 per cent neutral solution of hydrogen peroxid is a convenient means of quantitatively oxidizing nitrous acid to nitric acid. In a solution containing both nitrous and nitric acids, nitrous acid is first determined in one portion by titration with permanganate, then in another portion of the solution the nitrous acid is oxidized with hydrogen peroxid to nitric acid and determined by means of nitron (E. S. R., 16, p. 945).

Examination of water, W. P. MASON (*New York: John Wiley & Son*, 1906, 3. ed., *rev.*, pp. 155, pls. 3, figs. 11).

Contribution to the determination of nitric acid in water, P. DRAWE (*Chem. Ztg.*, 30 (1906), No. 43, pp. 530, 531).—A modification of Frerichs' method (E. S. R., 14, p. 946) is described and recommended.

Modern methods of testing milk and milk products, L. L. VAN SLYKE (*New York: Orange Judd Co.; London: K. Paul, Trench, Trübner & Co., Ltd.*,

1906, pp. XVII+214, pl. 1, figs. 56).—This book has been prepared for the use of dairy students, butter makers, cheese makers, milk inspectors, etc., rather than for the chemist, and the methods described are such as do not necessarily require previous chemical training for their successful operation. The Babcock test is very fully considered. Chapters dealing with methods of commercial testing and scoring of butter, cheese, milk, and cream are included. The final chapter gives rules for the various arithmetical calculations frequently necessary in testing milk and milk products, with illustrative examples.

On the oxidation index of milk, E. COMANUCCI (*Abs. in Chem. Ztg.*, 30 (1906), No. 41, p. 564).—In determining the oxidation index of milk, which is believed to furnish important information concerning the quality of milk, 10 cc. of milk is diluted with water to 1 liter, 20 cc. of dilute sulphuric acid (1 to 5) added to 10 cc. of this solution, the mixture warmed to 60 to 70° C. on the water bath, and decinormal potassium permanganate solution added drop by drop until the appearance of a rose-red color remaining for 5 minutes. The number of cubic centimeters of permanganate solution required for the oxidation of 1 cc. of milk, the author calls the oxidation index. As a result of numerous determinations, the following indexes were found: Cows' milk 50 to 52, goats' milk 44 to 45, sheep's milk 43 to 48, asses' milk 55 to 58, and human milk 53 to 60. The oxidation index of milk diluted with 10 per cent of water was 44, with 50 per cent 25, and with 90 per cent 5.

Note on a recent paper by R. Steinegger on the "aldehyde figure" of milk, H. D. RICHMOND and E. H. MILLER (*Analyst*, 31 (1906), No. 364, pp. 224-226).—Steinegger's method (*E. S. R.*, 17, p. 696) is considered important because it gives (1) an approximate estimation of the amino-nitrogen, (2) an indirect but easy method for determining proteids, and (3) another easily determined figure capable of furnishing corroborative evidence.

In mixed milk sodium hydroxid was found to give a mean aldehyde figure of 18.4 and strontium hydroxid, 20.2, expressed in cubic centimeters of normal alkali per liter of milk. Assuming a proportion of casein to albumin in milk of 7:1, the authors find that 1 cc. of tenth normal soda corresponds to 0.0298 gm. of the nitrogen of milk and 1 cc. of tenth normal strontia to 0.0271 gm. Steinegger's average was 0.0303. The maximum, minimum, and average of 113 determinations of the aldehyde number were respectively 22.6, 18.1, and 19.9, expressed in cubic centimeters of normal strontia per liter of milk.

The estimation of fat in homogenized milk, H. D. RICHMOND (*Analyst*, 31 (1906), No. 364, pp. 218, 219).—As homogenized milk, prepared by forcing milk under a pressure of from 200 to 400 atmospheres through very small openings, is now an article of commerce, the author sought to ascertain what effect the fine state of division of the fat globules would have upon the determination of fat by ordinary methods. The Gottlieb, kieselguhr, and Werner-Schmid methods gave results in almost perfect agreement. Good results were also secured by the Gerber method. The Adams method, however, was always low. In the opinion of the author this method, so long a standard, should be discarded in favor of the Gottlieb method, which, for ease and accuracy, is considered the best method for this purpose.

The analysis of dried milk, H. D. RICHMOND (*Analyst*, 31 (1906), No. 364, pp. 219-224).—Several modifications of methods used for ordinary milk considered necessary in examining dried milk or milk powder are noted and analyses of 7 samples are given.

The Werner-Schmid method is considered suitable for determining fat which can not be estimated by direct extraction. In determining milk sugar polarimetrically, 10 gm. of the sample is ground up in a mortar with sufficient hot

water to make a paste and then gradually thinned with hot water and finally made up to 100 cc. If the powder is not all dissolved a little ammonia may be added. Cane sugar is determined by the method described by Harrison (*E. S. R.*, 16, p. 846). Proteids are calculated from the total nitrogen of the Kjeldahl method by the factor 6.87.

Two of the samples examined were apparently made from skim milk, two had received an addition of saccharate of lime, one an addition of a phosphate, two an addition of cane sugar, and one an addition of sodium carbonate. Only one sample was made without the addition of any substance designed to render the dried milk more soluble.

Determination of the proteids in milk, A. TRILLAT and E. SAUTON (*Ann. Chim. Analyt.*, 11 (1906), No. 6, pp. 205-207).—Five cc. of milk is diluted with water to 25 cc., boiled for 5 minutes and treated with 5 drops of commercial formalin. After again boiling for 2 to 3 minutes and allowing to stand for 5 minutes, 5 cc. of a 1 per cent solution of acetic acid is added. The fine precipitate is then collected on a weighed filter, washed with water, and the fat extracted with acetone in a Soxhlet extraction apparatus. The fat-free material is then dried at 75 to 80° C. and weighed. The entire operation occupies less than 2 hours. The fat may be determined by evaporating the acetone. The method is applicable to milk preserved with potassium bichromate.

Estimation of casein. A preliminary study, H. V. ARNY and T. M. PRATT (*Amer. Jour. Pharm.*, 78 (1906), No. 3, pp. 121-128).—In the volumetric method proposed a definite quantity (5 to 30 cc.) of milk is treated at ordinary temperatures with 20 cc. of decinormal ferric alum solution (48.1 gm. per liter), the mixture diluted with water, allowed to stand for a few minutes, filtered, the filter washed until free from iron, and the excess of ferric alum in the filtrate determined by titration with potassium iodid, hydrochloric acid, and decinormal sodium thiosulphate. The difference between the amount of ferric alum taken and that found in the filtrate gives the quantity required for the precipitation of the casein. Concordant results were obtained in numerous determinations. Experiments indicated that the reaction is not affected by the fat and sugar in the milk. Comparative determinations were made to establish a relationship between the quantity of ferric alum solution required to precipitate the casein and the nitrogen in the precipitate as determined by the Kjeldahl method, but further work is considered necessary in order to establish a definite standard.

The determination of fat in cheese, M. WEIBULL (*Svensk Kem. Tidskr.*, 17 (1905), No. 6, pp. 146-148).—The author recommends the Gottlieb method for the determination of fat in cheese. The results obtained by this method were somewhat higher than those obtained by the ordinary extraction method and the Schmidt-Bondzynski hydrochloric-acid method.—F. W. WOLL.

Chemistry in the kitchen and household, G. ABEL (*Chemie in Küche und Haus*, Leipzig: B. C. Teubner, 1905, pp. VI + 162, figs. 6).—In this volume, which is designed for popular use, some of the principles of chemistry are discussed with special reference to the household. The bulk of the volume deals with the application of chemistry in the home, the special topics treated being fire, lighting and heating, cooking utensils, etc., animal foods, vegetable foods, and condiments.

Chemical department, E. F. LADD (*North Dakota Sta. Rpt.* 1905, pp. 15-22).—In addition to meteorological observations noted elsewhere, this report contains analyses of several proprietary stock foods, 3 samples of manure, and 11 of Paris green.

Report of the chemist, R. F. HARE (*New Mexico Sta. Rpt.* 1904, pp. 36-46).—This report on the work of the chemical department during the year

includes analyses of 136 samples of bat guano and 6 samples of soil. Determinations are also given of the moisture in the soil and the protein content of the wheat of 25 plats. The results are interpreted as indicating a very slight increase of protein in wheat grown on soil with a limited amount of moisture.

The chemical laboratory of the Swedish Royal Agricultural Academy, 1856-1906, H. G. SÖDERBAUM (*Stockholm, 1906, pp. 60, figs. 6*).—A sketch of the laboratory with biographical notes of the directors, A. Müller, C. E. Bergstrand, L. F. Nilson, and the present author, and a complete bibliography of the publications of the laboratory during the past 50 years.—F. W. WOLL.

Report of the chemical control station at Trondhjem, 1905, E. SOLBERG (*Christiania, 1905, pp. 58*).—The report contains the usual tabular statements of the results of analyses of agricultural products made during the year, including soils, soil amendments, fertilizers, peat and peat litter, feeding stuffs, dairy products, human foods, also seed analyses.—F. W. WOLL.

METEOROLOGY—WATER.

Practical treatise on the weather, O. FREYBE (*Praktische Wetterkunde, Berlin: P. Parey, 1906, pp. VIII + 173, illus.*).—This claims to be a simple explanation of the use of weather maps in connection with local weather observations.

Instructions for cooperative observers (*U. S. Dept. Agr., Weather Bur. Doc. 347, pp. 31, figs. 10*).—This is the third edition of this pamphlet, which is designed "to furnish cooperative observers with brief instructions for their guidance in taking and recording observations, more especially of temperature and rainfall."

Summaries of temperatures, rainfall, sunshine, and evaporation, E. F. LADD (*North Dakota Sta. Rpt. 1905, pp. 16-19*).—These summaries show that the mean temperature for 1905 was 39.43° F., the maximum 93, in August, the minimum -34, in February. The total rainfall was 30.76 in. The average monthly evaporation from water surface for the 5 months May to September, 1905, was 5.29 in. A summary of observations on evaporation for the same period during the 4 years 1902-1905 shows that during 1902 the evaporation was 1.96 times the rainfall for the same period, in 1903 it was 2.58 times as great, in 1904 it was 2.47 times as great, and in 1905 the rainfall as compared with evaporation was as 1 to 1.003—that is, the evaporation was practically equivalent to the rainfall.

Studies on the diurnal periods in the lower strata of the atmosphere, F. H. BIGELOW (*U. S. Dept. Agr., Weather Bur. Doc. 344, pp. 51, figs. 71*).—Articles published separately in the Monthly Weather Review, February to August, 1905, are combined in this document. The subjects treated are diurnal periods of temperature, barometric pressure, vapor tension, the electric potential, coefficient of dissipation, terrestrial magnetic field, and the aperiodic disturbances; the variable action of the sun and its effect upon terrestrial weather conditions; and a general review of the status of cosmical meteorology.

Meteorological service for forecasting weather, H. DUFOUR (*Chron. Agr. Vaud, 19 (1906), No. 9, pp. 276, 277*).—A brief statement regarding the organization of the meteorological service of the Swiss department of agriculture and commerce with reference to dissemination of weather forecasts, especially by means of telephones.

Meteorology of Tunis, winter of 1905-6, G. GINESTOUS (*Bul. Dir. Agr. et Com. [Tunis], 10 (1906), No. 38, pp. 114-128, pl. 1*).—A summary of observations on pressure, temperature, rainfall, evaporation, humidity, etc., at a large number of stations in different parts of Tunis.

A contribution to the study of spring and fall frosts, E. VANDERLINDEN (*Ann. Serv. Mété. Observ., 1905; abs. in Rev. Gén. Agron., n. ser., 1 (1906), No. 3, p. 103*).—A note is here given on studies reported in the annual report of the Meteorological Service of the Royal Observatory for 1905 of conditions under which frosts are formed in the region of Uccle and of means of predicting frosts.

The conclusion is reached that the occurrence of spring and fall frosts is determined largely by local conditions. The three principal meteorological conditions which are believed to determine the occurrence of such frosts in the region in which the observations reported were made are (1) an anticyclone covering a large part or all of Europe, (2) a low to the east or northeast and an anticyclone to the west, (3) a low to the south of Europe and a high to the north. Many other conditions have an influence in the formation of white frosts. The determination of dewpoint was found to be an unreliable indication of night frosts. The theory that there is a constant relation between the temperature shown by the wet bulb thermometer at a given hour and the minimum night temperature was not verified in these investigations, and this instrument therefore did not prove reliable as a means of predicting frosts.

Balloons and kites in the service of meteorology, W. H. DINES (*Nature [London], 74 (1906), No. 1906, pp. 35, 36*).—This is a brief summary of progress which has been made in the study of the upper atmosphere by means of balloons and kites.

Recent practice in the erection of lightning conductors, A. J. HENRY (*U. S. Dept. Agr., Weather Bur. Bul. 37, pp. 20*).—The principal contents of this bulletin are a description of the lightning conductors on the Washington Monument; the preface to the Report of the Lightning Research Committee, by Sir Oliver Lodge; the rules for the erection of lightning conductors as issued by the Lightning Rod Conference of 1882, with observations thereon by the Lightning Research Committee of 1905, and brief statements of the latest practice abroad, in Holland, Hungary, and Germany.

[Amount of nitrogen as ammonia and nitrates in rain water collected at Pretoria], H. INGLE (*Transvaal Agr. Jour., 4 (1905), pp. 104, 105; abs. in Jour. Chem. Soc. [London], 90 (1906), No. 523, II, p. 302*).—Determinations of ammonia, nitrates, and nitrites in weekly samples of rain water collected at Pretoria during the year ended June 30, 1905, are reported. The results for the year are as follows: Rainfall 24.31 in., ammoniacal nitrogen 1.194 parts per million, nitric nitrogen 0.196 part; ammoniacal nitrogen per acre 6.587 lbs., nitric nitrogen per acre 1.083 lbs. The ammoniacal nitrogen was on the average 85.9 per cent of the total nitrogen. The nitrogen as ammonia varied from 0.32 (week ending March 18) to 45 (week ending August 27) per million, the rainfall being 70.36 mm. and 1.06 mm., respectively. The nitrogen as nitrates varied from 0.03 to 3.75 per million (rainfall 10.08 and 0.38 mm.). Nearly the whole of the nitrogen in the rain is brought down during the growing season."

Water and the law of minimum in the fertilization of soils, L. THURY (*Bul. Soc. Chim. Belg., 19 (1905), No. 8-9, p. 266*).—The rôle of water from the chemical, physical, biological, and electrical standpoints is discussed. Intensive culture is shown to reduce the water content of soil. This must be returned directly by irrigation or indirectly by improved methods of culture if the productive capacity of the soil is to be maintained.

Underground water resources of Long Island, New York, A. C. VEATCH ET AL. (*U. S. Geol. Survey Prof. Paper No. 44, pp. 394, pls. 34, figs. 71*).—This is a detailed report of studies of the geology and underground water conditions of Long Island, including also tests of methods of measuring velocity of underflow, data regarding wells, sizing and filtration tests, and descriptions of surface streams. It is shown that the conditions on the island are such as to cause it

to readily absorb, filter, and store the rain water, and thus to furnish large quantities of very pure water.

A study of the process of nitrification with reference to the purification of sewage, HARRIETTE CHICK (*Proc. Roy. Soc. [London], Ser. B, 77 (1906), No. B 517, pp. 241-266, fig. 1; abs. in Jour. Chem. Soc. [London], 90 (1906), No. 522, 11 p. 245*).—The process of nitrification was studied in experimental laboratory filters acting both as continuous filters and contact beds. It was found that nitrification of ammonia during sewage purification occurred in two stages due to activity of two distinct classes of bacteria, one producing nitrites and the other oxidizing the nitrites to nitrates. These bacteria exist not only in the substance of the filter, but are also carried away in large quantities in the filtrates. They belong to the same group as those producing nitrification in the soil. The action of the organisms producing nitrates may be retarded when the sewage is strongly ammoniacal.

The ability of the nitrifying organisms to live and work in sewage filters so highly charged with organic matter is discussed. This is ascribed to (1) the presence of organisms in symbiosis with the nitrifying organisms, rendering the latter more resistant; (2) the retention of the organic matter in large part near the surface of the filters; and (3) the presence of very large numbers of nitrifying organisms in the filters.

The influence of temperature on the oxidation of sewage was studied, and it was observed that the efficiency of the filters and the rapidity of the process of oxidation were greatly increased by raising the temperature. In any case nitrification was extremely rapid, being completed during the time required for percolation, 2 to 3 hours. The continuous filters were more efficient than contact beds in purifying the sewage.

The purification of sewage, W. RAMSAY (*Österr. Chem. Ztg., 9 (1906), No. 10, pp. 135-139*).—This is a paper which was presented before the Sixth International Congress of Applied Chemistry, Rome, 1906, which discusses the loss of fertilizing matter, particularly nitrogen, in sewage, and the various methods of sewage disposal which have been proposed. The difficulties in the way of the successful use of the irrigation method alone are pointed out.

SOILS—FERTILIZERS.

Some peculiarities of rock weathering and soil formation in the arid and humid regions, E. W. HILGARD (*Amer. Jour. Sci., 4. ser., 12 (1906), No. 124, pp. 261-269*).—The author summarizes in this article his observations and conclusions regarding various phases of this subject, especially as regards soil formation, which have been recorded in various previous publications. It is made clear that the processes of soil formation in arid regions are very different from those operating in humid regions and show "the need of caution in applying the maxims of the humid region in arid climates."

On the changes which minerals undergo in cultivated soil, T. BIÉLER (*Bul. Soc. Nat. Agr. France, 66 (1906), No. 2, pp. 186-195*).—The author presents evidence to show that the solution of silicates in the soil is a very complex and gradual process, resulting in partial or total decomposition of these compounds under the action of various factors working in association. Among these factors, which are enumerated and discussed, are chemical decomposition, and the solvent action of air and water, of organic matter, roots, and micro-organisms.

The wire-basket method for determining the manurial requirements of soils, F. D. GARDNER (*U. S. Dept. Agr., Bur. Soils Circ. 18, pp. 6, figs. 2*).—The methods of constructing the wire baskets and of using them in determining the manurial requirements of soils are described (see E. S. R., 17, p. 227).

Soil analysis and agricultural charts in Italy, G. FASCETTI (*Abs. in Ztschr. Angew. Chem.*, 19 (1906), No. 20, pp. 913, 914).—The need of systematic soil examination and charting is pointed out. It is claimed that this work should be done with the aid and under the supervision of the Ministry of Agriculture in order to secure uniformity of methods and results.

The soils of Victoria, T. CHERRY (*Year Book Agr. Victoria*, 1905, pp. 29-44).—The physical features of Victoria with especial reference to soils are briefly described, and analyses of 190 samples of typical soils are reported and discussed. The average results of the analyses are given in the following table in comparison with typical English and American soils:

Average composition of Victorian and other soils.

	Number of samples.	Soils.					Subsoils.				
		Nitrogen.	Phosphoric acid.	Potash.	Lime.	Chlorin.	Nitrogen.	Phosphoric acid	Potash.	Lime.	Chlorin.

The characteristics of the soils of the different classes are quite fully described. In general it was found that judged by European standards the amount of fertilizing matter in Victorian soils is often small, but "the marvelous growth that occurs everywhere when the rain comes after a dry spell shows that there are forces at work during the months of bright sunshine which are very friendly to the husbandman." Small applications of super-phosphate sometimes prove beneficial, but applications of nitrogen in many cases actually reduce the yield.

Some preliminary notes on the physical properties of the soils of the Ganges Valley, more especially in their relation to soil moisture, H. M. LEAKE (*Jour. Agr. Sci.*, 1 (1906), No. 4, pp. 454-469).—This article reports a series of observations extending over about one year with reference to the temperature, moisture, and other conditions under which indigo is grown on these soils, with the ultimate object of finding means of rendering these as favorable as possible. Observations on rainfall, temperature, humidity, methods of cultivation, general physical properties of the soils, and studies of specific gravity and soil moisture (to a depth of 8 inches) and its movement are reported, and bring out the following points:

"(1) A large daily evaporation is taking place from the surface of the soil.

"(2) This evaporation is entirely, or in greater part, counteracted by a large upward flow of moisture from a lower level and ultimately from the ground water."

Some banana soils of St. Mary and Upper St. Catherine [Jamaica], H. H. COUSINS (*Bul. Dept. Agr. [Jamaica]*, 4 (1906), No. 2, pp. 25-33).—The results of examinations with reference to mechanical condition and percentages of lime as carbonate and humus soluble in ammonia of 39 samples of typical

banana soils are reported, and the condition and needs of the soils are discussed. The examinations were limited to the three points named because previous analyses and experiments had indicated that the soils are not in present need of commercial fertilizers, but require special attention to drainage and humus and in some cases lime.

The lime content of some esparcet soils, F. G. STEBLER (*Landw. Jahrb. Schweiz*, 20 (1906), No. 3, pp. 177-180).—Examinations of a number of soils on which esparcet was grown show that this and like plants can be successfully grown only on soils containing very small amounts of calcium carbonate and of good physical properties.

Regeneration of overlimed soil, S. MAKI and S. TANAKA (*Bul. Col. Agr., Tokyo Imp. Univ.*, 7 (1906), No. 1, pp. 61-65, fig. 1).—Pot experiments with barley are reported which indicate that only one-twentieth as much magnesia (MgO) in sulphate as in magnesite is needed to bring about favorable conditions for barley on overlimed soil.

On the formation of humus, S. SUZUKI (*Bul. Col. Agr., Tokyo Imp. Univ.*, 7 (1906), No. 1, pp. 95-99).—Observations on decomposition of oak leaves in flasks under different conditions show "that magnesium carbonate promoted the development of carbonic acid, while calcium carbonate retarded it," and lead to the conclusion that "the humification process is promoted by magnesium carbonate and retarded by calcium carbonate." The addition of soluble phosphate overcame in a measure the retarding action of the calcium carbonate. An examination of the physical and microscopic properties of the leaves indicated that "the change in color and brittleness and also the development of mycelium go parallel with the development of carbonic acid. . . ."

"After sterilization and introduction of the peculiar kind of *Penicillium* known thus far only under the name of 'Schokoladenfarbener Schimmelpilz' the humification process proceeded much slower than under the original conditions."

Plant nutrition studies, E. B. VOORHEES and J. G. LIPMAN (*New Jersey Stat. Rpt.* 1905, pp. 211-221, pls. 6).—The methods and appliances devised for "a comprehensive study, first, of the needs for plant food of certain rather well-defined soil types, when used for general farming; and second, the mineral requirements in the growth and development of legumes" are described, and the first year's results with cowpeas, oats, and oats and cowpeas on red shale soil classed as (1) good (producing 20 bu. of wheat per acre), (2) medium (producing 15 bu. of wheat), and (3) poor (producing 10 bu.) are reported.

"While these studies were carried out by means of the pot system, in which small amounts of soil are used under controlled conditions, the system used varied somewhat from that generally practiced in work of this character, where the pots are carried on trucks, which may be run to shelter during showers or rainy weather. The system adopted avoided the removal of the pots from the open air at any time, prevented an undue raising of the temperature, as the surfaces of the pots were not directly exposed to the atmosphere, and provided an easy means of weighing for controlling the amount of water added. The system may be described as follows: . . . In the first place, a framework was erected, 3 ft. high, 3 ft. wide, which was enclosed with matched boards, with openings on the top for insertion of the pots. . . ."

"In order to protect the jars from heat radiated from the covering of the frame, boards were nailed to cleats on the inside, thus providing an air space between the jars and the outside covering.

"An iron ring of the same diameter as the hole for the jar was placed on the top of the box for each jar, in order to facilitate weighing the jars without

removing them from the box. This, together with the balance used, is shown in figure 1. The jars were the ordinary museum jars, without tops, having an extended flange at the top, serving as a support for the jar, though the cross-pieces were carried through the frame under the boxes in order to relieve any sudden strain upon the flange. These jars were $7\frac{1}{2}$ in. in diameter and 10 in. deep. They were all tared by adding small quartz pebbles, and each contained exactly 20 lbs. of soil. In order to protect the plants from high winds and from rain, a detachable roof was made by a framework, hinged in the middle and covered with duck. In order to provide for the growth of the plants stakes were fastened to the sides of the frame, with holes bored in them at different distances. The roof could, by this device, be adjusted at different heights, and was held in place by means of iron staples."

The detailed results of studies of the effect of small, medium, and large amounts of potash and phosphoric acid on the growth of the cowpeas and of small, medium, and large amounts of potash, phosphoric acid, and nitrogen on oats are reported, but no conclusions are drawn.

"The experiments begun in Hammonton in 1904, to study methods of development of the light soils, as well as their adaptability for the growing of forage crops, were continued through the present year." The object in the first case is "to grow profitable forage crops, in succession, by the use of commercial fertilizer alone." Data are given for crops of crimson clover followed by soy beans, rye

FIG. 1.—Balance for weighing soil pots.

and vetch followed by corn, red clover followed by millet, wheat followed by cowpeas, and oats and vetch grown in 1905.

The measure of soil fertility from the nitrogen standpoint, J. G. LIPMAN (*New Jersey Stat. Rpt. 1905, pp. 225-280*).—This is a review and contribution to the study of the biological activities of the soil bearing upon the various processes of nitrogen fixation, decay, nitrification, and denitrification, each of which plays a certain rôle in the nitrogen feeding of the crop, with a view to finding means "to intensify the desirable processes of nitrogen fixation and nitrification; to suppress the objectionable denitrification, where it is at all apt to take place; to suppress, likewise, the too rapid oxidation of the organic matter, and those phases of decay that might lead to the liberation of elementary nitrogen."

Series of studies of ammonia production in peptone solution inoculated with soils of different kinds fertilized in various ways and of experiments with *Azotobacter* cultures isolated at various times in 1903, 1904, and 1905 are reported.

"The cultures of *Azotobacter vinelandii*, isolated at the beginning of 1903 and kept in the laboratory since that time, were found to have lost none of their nitrogen-fixing power. A similar comparison of fresh cultures of *A. beyerincki* with those isolated a year earlier showed that also this species had retained its original power of fixing atmospheric nitrogen. As to the quantitative production of combined nitrogen, *A. vinelandii* is markedly superior to either *A. beyerincki* or *A. chroococcum*, with an output frequently more than double that

produced by either of the other species. *A. beyerincki* and *A. chroococcum*, while quite different in their cultural characteristics, are physiologically alike in so far, at least, as their power of nitrogen fixation is concerned. Like *A. vinelandii*, these two species may also increase their output of combined nitrogen when growing together with certain smaller bacilli."

Investigations on the biology of nitrogen-fixing bacteria: A contribution to the knowledge of the variations in nitrogen content of bare soils, II. WARMBOLD (*Landw. Jahrb.*, 35 (1906), No. 1-2, pp. 1-123; *abs. in Chem. Centbl.*, 1906, I, No. 12, p. 1041).—In this article the author reviews with considerable fullness previous investigations on denitrification and nitrogen fixation in the soil, discusses the general conditions controlling such changes in nature, and reports a series of experiments on the influence of temperature, water content, aeration, associative action of pure and mixed cultures, etc., on these processes.

The principal conclusions drawn from the results obtained are as follows: Sterilized soils of very porous structure, containing 16 to 30 per cent of water, when subjected to thorough aeration fixed nitrogen to an appreciable extent, indicating that under certain conditions there is a chemical fixation of nitrogen in the soil without intervention of organisms. This is in agreement with results obtained by Berthelot. The increase in nitrogen of both sterile and unsterilized soils was dependent to a considerable extent upon the temperature. The water content of thin layers of porous soils in which aeration was not interfered with exerted no appreciable influence on the nitrogen content of the soil. In pot experiments with larger amounts of soil (about 13½ kg.) the water content exerted a very appreciable influence. In such cases the most desirable water content from the standpoint both of preservation and increase of nitrogen in the soil was 20 per cent. With 10 per cent and less there was either no increase or a very decided decrease of soil nitrogen, the loss of nitrogen being especially large in case of the lighter soils. The loss of nitrogen with a water content of less than 3 per cent can not be ascribed to denitrification, but must be due to some purely chemical process, since nitrates were not present at the beginning of the experiment and the nitrifying organisms could not develop with so small a water content.

The growth of algae on the surface of the soil favored an increase of nitrogen in the soil, but it is not clear whether this was due to nitrogen assimilation by the algae or to their influence in retarding denitrification. With large amounts (about 3 kg.) of sterile soils a water content of 3 to 20 per cent did not influence the nitrogen content. With a water content of 30 per cent, however, a loss was observed. No influence of aeration on the nitrogen content of soils was observed in case of small amounts (150 gm.) of soils in thin porous layers either in sterile or in unsterilized condition. In pot experiments with about 13½ kg. of soil and 15 per cent of moisture thorough aeration increased the nitrogen content.

The use of artificial humus favored the fixation of nitrogen, indicating that this material is a suitable source of carbon in artificial culture media for soil bacteria. With a temperature of less than 5° C. or greater than 50° C. there was no fixation of nitrogen in the artificial cultures. The most favorable temperature zone for nitrogen fixation in artificial cultures lies between 18 and 21° C. Wide variations were observed in the capacity for fixation of nitrogen of the various organisms experimented with, both in pure cultures and in mixed cultures. In artificial cultures of *azotobacter* weak diffused light appeared to exert a favorable influence upon nitrogen assimilation.

Some work of the Agricultural-Bacteriological Institute of Göttingen University, A. KOCH (*Mitt. Deut. Landw. Gesell.*, 21 (1906), No. 10, pp. 111-115).—A brief review is given of recent investigations at this institute on

nitrogen-fixing bacteria, the influence of carbon bisulphid in increasing the yield of crops, green manuring, solvent action of bacteria on phosphatic fertilizers, and a source of error in estimating the yield of cereals.

The author's experiments show that the activity of the nitrogen-fixing bacteria is controlled more by the temperature of the soil than by the nutrient materials available. For example, in soil supplied with sugar and kept at a temperature of 7° C. there was no fixation of nitrogen. When, however, the temperature was raised to 15, or better, 21°, there was rapid fixation of nitrogen. Moreover, in presence of substances such as sugar, which promote the action of the denitrifying organisms, denitrification is more likely to prevail at the lower temperatures than at the higher. Raising the temperature apparently enables the nitrogen-fixing organisms to overcome the denitrifying organisms.

Observations on the effect of carbon bisulphid on the organisms of the soil indicate that the use of large quantities of this material does not prevent denitrification, a result which does not bear out Hiltner and Störmer's explanation of the action of this substance in increasing the yields of crops.

Experiments are reported which show that the turning under of mustard as a green manure resulted in a loss of nitrogen from the soil, the cause of which was not ascertained.

The author's investigations confirm those of Stoklasa in showing that soil bacteria and other lower organisms produce acids in the soil which aid in dissolving and rendering assimilable the difficultly soluble phosphates.

Data are reported to show that the appearance of crops in the field is by no means an accurate index of their actual yield when harvested.

On the question whether nitrites or nitrates are produced by nonbacterial processes in the soil, E. J. RUSSELL and N. SMITH (*Jour. Agr. Sci.*, 1 (1906), No. 4, pp. 444-453).—The experiments reported in this article "were made with a view to discover how far purely physical and chemical processes, known to take place in the soil, may be expected to give rise to nitrites and nitrates." They dealt with the possibility of the formation of nitrites and nitrates during (1) the evaporation of water, (2) the oxidation of free nitrogen by catalytic processes and induced oxidation, and (3) the oxidation of ammonia. The first dealt mainly with a study of Schönbein's observations, from which he concluded that ammonium nitrite is produced when water is evaporated in air; the second with the catalytic action of platinum black as studied by Loew, ferric oxid as studied by Bonnema, humus, and soil; and the third with the oxidation of ammonia in the soil by catalytic action and induced oxidation.

The results as a whole are claimed to show conclusively that there is no measurable formation of nitrites or nitrates in the soil from atmospheric nitrogen or from ammonia by chemical or physical processes and that under no circumstances does the evaporation of water produce ammonium nitrite. The evidence as to the oxidation of free nitrogen by catalytic or induced oxidation processes in the soil is not conclusive, but the results obtained in the experiments reported indicate "that if induced oxidation takes place at all its effects are so extremely slight that in practice they would be altogether negligible.

"Catalytic oxidation of nitrogen does not seem to occur in the soil.

"Slightly different results were obtained with ammonia. As the higher oxids of iron and manganese possess a slight power of catalytically oxidizing ammonia, it might be expected that soils in which they occur to any extent would possess the same power; in any case, however, the effect is only small, and appears to be of no practical consequence.

"On the other hand, ammonia oxidizes more readily in presence of other sub-

stances undergoing oxidation. Experiments with soils showed that this induced oxidation may, under certain rather artificial circumstances, come into play as a factor in producing nitrates; but it must be remembered that at the low partial pressures of ammonia obtaining in nature, bacterial nitrification would be more prominent than in our experiments. Taking this point into consideration, the induced oxidation of ammonia can not be regarded as an important source of nitrates under natural conditions."

The fixation of atmospheric nitrogen during the decomposition of forest leaves, L. MONTEMARTINI (*Staz. Sper. Agr. Ital.*, 38 (1905), No. 10-12, pp. 1060-1065).—Carefully conducted experiments with 50 to 60 gm. lots of plane-tree, alder, hornbeam, and oak leaves sterilized and inoculated with extracts of decomposing leaves showed a considerable gain of nitrogen in the course of decomposition during the period from about the end of November to the last of March, thus confirming Henry's claim (*E. S. R.*, 9, p. 1041; 15, p. 764) that during the process of decomposition of the leaves of trees there is a fixing of atmospheric nitrogen and that such fixation does not take place when the material studied is sterilized, thus signifying that the phenomenon is due to the presence of micro-organisms.

Investigations relative to the use of nitrogenous materials, E. B. VOORHEES and J. G. LIPMAN (*New Jersey Stas. Rpt.* 1905, pp. 138-211).—The experiments of previous years (*E. S. R.*, 17, p. 344) were continued during 1904 and 1905, the crop grown in this year being oats. "The two oat crops of the first rotation added to those of the second rotation furnish an abundance of experimental material, which may be used to demonstrate how a one-sided system of fertilization affects the crop-producing power of the soil. It becomes clear here what the comparative value of nitrate, ammonia, or organic nitrogen may be and to what extent they may be used as a source of nitrogen when applied alone or together with animal manures."

The relative availability of the nitrogen of the nitrogenous materials, as shown by the four crops of oats, is given in the following table:

The availability of nitrogen in different nitrogenous materials with oats.

	1899.	1900.	1904.	1905.
Sodium nitrate.....	100.0	100.0	100.0	100.0
Ammonium sulphate.....	77.9	87.7	64.7	78.1
Dried blood.....	61.3	73.1	65.2	53.5
Solid manure, fresh.....	43.1	26.4	48.6	33.2
Solid manure, leached.....	46.4	22.0	40.3	42.7
Solid and liquid manure, fresh.....	88.4	51.5	71.0	37.8
Solid and liquid manure, leached.....	33.0	35.9	52.9	42.3

On the direct utilization of the nitrogen of the air for the preparation of fertilizers and other chemical products, A. FRANK (*Ztschr. Angew. Chem.*, 19 (1906), No. 19, pp. 835-840; *Chem. Ztg.*, 30 (1906), No. 38, p. 449).—A paper before the Sixth International Congress of Applied Chemistry at Rome, 1906, which reviews the history of investigation and invention in relation to this subject, the progress made in establishment of manufacturing enterprises, as well as experiments to test the value of the product for industrial and agricultural purposes.

Comparative fertilizer tests of lime nitrogen and nitrate of soda on oats, R. OTTO (*Deut. Landw. Presse*, 33 (1906), No. 32, p. 275).—The two materials were applied on light soils in amounts furnishing equal rations of nitrogen. The lime nitrogen was applied about one week before the seeding of the oats.

The results were in all cases favorable to the lime nitrogen except that the grain produced with this fertilizer contained a somewhat smaller percentage of nitrogen than that produced with nitrate of soda.

Calcium cyanamid and calcium nitrate, two new fertilizers derived from atmospheric nitrogen, and results of their use, H. VON FEELITZEN (*Österr. Moor. Ztschr.*, 7 (1906), p. 38; *abs. in Chem. Ztg.*, 30 (1906), No. 34, *Reperit. No. 12*, p. 143).—The fertilizing value of these materials is discussed, especial attention being given to the results of tests of hygroscopic and basic calcium nitrate in comparison with sodium nitrate. It was found that these materials were about equally effective as fertilizers.

A new nitrogenous manure, lime nitrogen or calcium cyanamid, J. HENDRICK (*Trans. Highland and Agr. Soc. Scot.*, 5, ser., 18 (1906), pp. 75-77).—Comparative tests of calcium cyanamid, nitrate of soda, and sulphate of ammonia in pot and field experiments with oats and barley are reported. "The results show that the cyanamid gives returns very little behind those given by nitrate of soda or sulphate of ammonia."

Experiments with lime nitrogen as a fertilizer for sugar beets, F. STROHMER (*Österr. Ungar. Ztschr. Zuckerindus. u. Landw.*, 34 (1905), pp. 661-685; *abs. in Chem. Centbl.*, 1906, 1, No. 9, p. 781).—When applied 15 days before planting, the lime nitrogen produced no injurious effects and proved but little less efficient than sodium nitrate and superior to ammonium sulphate both as regards yield and quality of beets.

Experiments on the action of nitrogen lime, O. BÖTTCHER (*Deut. Landw. Presse*, 33 (1906), No. 34, pp. 289, 290).—Pot experiments on oats with so-called nitrogen lime (*Stickstoffkalk*), which is prepared by passing atmospheric nitrogen freed from oxygen over a fused mixture of calcium carbide and calcined calcium chloride and containing about 22 per cent of nitrogen, are reported. The results show that this material is very similar in its action to calcium cyanamid (lime nitrogen), that like it it should not be used as a top-dressing, and should be applied some time before planting seed.

Lime nitrogen, B. SJOLLEMA (*Cultura*, 18 (1906), Nos. 269, pp. 3-27; 210, pp. 90-97).—Investigations on the fertilizing value of lime nitrogen are quite fully reviewed and experiments by the author on rye and oats are reported which show that the lime nitrogen (180-270 lbs. per acre) was as a rule nearly as efficient as nitrate of soda and somewhat more so than sulphate of ammonia. A mixture of 134 lbs. of lime nitrogen and 180 lbs. of nitrate of soda per acre gave the highest increase in yield in case of rye.

The results of experiments with calcium cyanamid (lime nitrogen), A. POZZOLI (*Abs. in Chem. Ztg.*, 30 (1906), No. 38, p. 454).—This is an abstract of a paper presented at the Sixth International Congress of Applied Chemistry at Rome in 1906, reviewing the results of tests by various investigators of the fertilizing value of this material. It is pointed out that the results of a large number of experiments show that the action of this material varies widely with different plants.

Experiments by Frank are cited to show that the injurious effects observed in the use of lime nitrogen as a top-dressing in pot experiments would not be observed in practice where much smaller amounts of the material would be used. Experiments by the same investigator also indicate that the fear of injury from acetylene gas, which may be generated in small amounts when lime nitrogen is applied to soils, is groundless. Experiments with various plants showed no injury from the presence of this gas.

The various factors which influence the decomposition of calcium cyanamid, J. STOKLASA (*Abs. in Chem. Ztg.*, 30 (1906), No. 38, p. 455).—This is an

abstract of a paper presented at the Sixth International Congress of Applied Chemistry at Rome, 1906, dealing especially with the water and air capacity of cultivated soils in its relation to the bacteriological decomposition of calcium cyanamid in the soil. It is noted especially that in humus soils, in which the nitrification process goes on very slowly, calcium cyanamid shows very little effectiveness as fertilizer.

Vegetation experiments with "N" fertilizer in the year 1905, VON LEPEL (*Mitt. Deut. Landw. Gesell.*, 21 (1906), No. 3, pp. 19-24, figs. 5).—A series of field and pot experiments with this material on various crops is reported.

Previous experiments (E. S. R., 16, p. 860) having shown no injurious effects with the amounts of "N" fertilizer used, field experiments with rye, oats, wheat, potatoes, and beets, and pot experiments with barley, oats, maize, timothy, buckwheat, mustard, and flax were undertaken in 1905 to further study the limits of efficiency of this material as a fertilizer.

The results confirmed those of previous years in showing a high fertilizing efficiency for the "N" fertilizer on cereals and like crops (at rates of 50 lbs. per acre). Its value for hoed crops is, however, less certain.

Green manuring experiments in 1905, BAESSLER (*Mitt. Deut. Landw. Gesell.*, 21 (1906), No. 22, pp. 233-237).—Plat experiments which have been carried on in various localities for several years to determine (1) the best depth to which to plow under green manures, (2) the relative merits of spring and fall green manuring, (3) the utilization of the nitrogen of green manures by the following crop, are reported. Shallow plowing under (10 to 15 cm.) gave in general the best results. Spring green manuring appeared to be as a rule more effective than fall. The utilization of the nitrogen and the general effect of the green manure was found to vary widely with conditions of soil, season, etc.

Experiments with fertilizers, J. H. STEWART and H. ATWOOD (*West Virginia Sta. Bul.*, 99, pp. 185-210, pls. 6).—The results of 6 years' experiments with various kinds and combinations of fertilizing materials on tenth-acre plats on the station farm are summarized.

Mechanical and chemical analyses of the soil are reported. These show no striking peculiarities as regards chemical composition, but that the soil is a clay loam fairly well supplied with fertilizing constituents. The crops grown during the different seasons included rye, clover, wheat, corn, and cowpeas.

The results show that the yields were uniformly increased by applications of phosphoric acid. The only case in which nitrogen was beneficial was in the form of nitrate of soda applied as a spring top-dressing on rye. Potash in form of sulphate was of little or no value, and a mixture of potash and nitrogen gave like results. The indications are that the stock of available phosphoric acid in the soil is so low that this deficiency must be supplied before either nitrogen or potash can be of any particular value, and after the deficiency of phosphoric acid is supplied the plants feel the lack of nitrogen more than that of potash. Stable manure increased the yields materially and uniformly. The results of applications of lime were totally unsatisfactory, in many cases reducing the yield. In general it was observed that the fertilizer combination which gave good results with one crop in the series tested also gave good results with the others. That is, a fertilizer containing phosphoric acid gave good results with all of the crops tested. In a comparison of the effects of commercial fertilizers and barnyard manure it was found that corn responded more favorably to a dressing of stable manure than it did to an application of commercial fertilizers, while with cowpeas the opposite was true. It was observed also that although the roots of the cowpeas were well supplied with nodules, the yield was slightly increased by adding nitrate of soda to the fertilizer mixture applied.

In general it is held that "this experiment shows that this soil is very deficient in available phosphoric acid, and that as soon as this deficiency is supplied then there is a lack of nitrogen and to a less extent of potash also. When commercial fertilizers are relied upon entirely to maintain a high degree of crop production a fertilizer containing all three constituents—nitrogen, potash, and phosphoric acid—will give better results than a fertilizer containing only one or two of these constituents. . . ."

"If leguminous crops are raised and either plowed under or fed on the farm and the resulting manure carefully saved and applied to the soil it is very probable that in practice it will be necessary to purchase only phosphoric acid in order to increase the productiveness of soils of this type and to maintain them in a condition of high fertility.

"Stable manure has demonstrated again its great value as a restorer of fertility to a poor worn-out soil."

Results of cooperative experiments with fertilizers on swamp soils, R. HARCOURT (*Ann. Rpt. Ontario Agr. and Expt. Union*, 27 (1905), pp. 33-35).—The results of 11 cooperative experiments with oats and 7 with corn on swamp soil in different parts of Ontario are briefly reported. Potash (muriate) produced an increase in yield in every case and Thomas slag gave an increase in every case except two, the increase being in every case sufficient to make the use of fertilizers profitable.

Comparative tests of Peruvian guano and ammoniated superphosphate 9:9, A. ARNSTADT (*Deut. Landw. Presse*, 33 (1906), No. 19, pp. 159-161).—Experiments of previous years (E. S. R., 16, p. 758) were continued with oats and fodder beets. The results for 3 years are partly summarized, showing a high fertilizing value for the Peruvian guano as compared with the ammonium superphosphate.

The action of ammoniacal nitrogen as a fertilizer, T. PFEIFFER (*Fühling's Landw. Ztg.*, 55 (1906), No. 5, pp. 153-159).—Various causes for the frequently observed inferiority of ammoniacal nitrogen to nitrate nitrogen as a fertilizer are discussed. It is claimed that there are so many unknown factors causing wide variations in the efficiency of ammoniacal nitrogen that the only safe plan is for the farmer to make field experiments to test the matter for himself.

On the use of commercial nitrogen in connection with barnyard manure, BACHMANN (*Fühling's Landw. Ztg.*, 55 (1906), No. 5, pp. 180-183).—The conditions under which it is advisable to supplement farm manures with the more active commercial forms of nitrogen are discussed.

The use of waste organic substances as manures, E. J. RUSSELL (*Jour. Bd. Agr.* [London], 13 (1906), No. 2, pp. 65-72).—This article deals briefly with the use as fertilizer of dried blood, feathers and feather waste, greaves (refuse from making tallow or soap grease), hair, hoofs and horns, rabbit flick (rabbit waste, consisting of ears, feet, tail, etc.), slaughterhouse refuse, waste fish, damaged oil cake, shoddy, refuse from tanneries, destructor refuse, night soil and poudrette, and sewage sludges.

Action of phosphoric acid on higher plants and a new nutritive solution, C. VON DER CRONE (*Inaug. Diss. Bonn*, 1904; *Naturw. Rundschau*, 1905, p. 264; *abs. in Centbl. Agr. Chem.*, 35 (1906), No. 1, pp. 30-33; *Jour. Chem. Soc.* [London], 90 (1906), No. 521, II, pp. 191, 192).—Water culture experiments with different plants are reported which showed that when phosphoric acid was absent the root development was retarded and the roots were yellow when iron (as sulphate) was present. The addition of phosphate precipitated the iron and prevented its injurious action, but in this case the plants suffered from chlorosis. Good results were obtained when ferrous phosphate and tricalcium phosphate were added to the solution. When dicalcium phosphate was

used the plants were chlorotic and the root development was retarded. The author believes that the assumption that the constituents of the culture medium should all be in solution is incorrect. He recommends the following solution: Potassium nitrate 1 gm. per liter, calcium sulphate and magnesium sulphate each 0.5 gm., ferrous phosphate and tricalcium phosphate each 0.25 gm.

On phosphoric acid of ashes, D. N. PRIANISHNIKOV (*Abstr. in Chem. Ztg., 30 (1906), No. 37, p. 439*).—This is an abstract of a paper presented at the Sixth International Congress of Applied Chemistry at Rome, 1906, in which pot experiments are reported which show that the phosphoric acid of straw ashes is nearly as effective as that of soluble phosphates, the phosphoric acid of birch wood ashes is somewhat less effective, and that of fir wood ashes still less effective. (See also E. S. R., 17, p. 847.)

Analysis of deposits of calcium phosphate in the United States, P. JUMEAU (*Ann. Chim. Analyt., 11 (1906), No. 5, pp. 167-170*).—The location, extent, and composition of the hard rock deposits of Florida are discussed in this article. The following complete analyses of two samples of ground phosphate are given as representing the composition of products of good quality:

Composition of Florida hard rock phosphate.

	A.	B.
	<i>Per cent.</i>	<i>Per cent.</i>
Moisture.....	1.80	1.08
Loss at red heat.....	1.10	1.00
Phosphoric acid.....	a 35.44	b 35.82
Lime.....	47.30	47.47
Iron oxid.....	.70	.72
Alumina.....	1.60	1.48
Silica and insoluble.....	3.70	5.30

aCorresponding to calcium phosphate, 77.43 per cent.

bCorresponding to calcium phosphate, 78.26 per cent.

The utilization of sugar beet slump by the Dessau method, H. OST (*Ztschr. Angew. Chem., 19 (1906), No. 14, pp. 609-615, figs. 4*).—The preparation of cyanids, ammonium sulphate, and other products from this material is briefly described. It is shown that in general about one-half of the nitrogen of the slump is utilized by the various processes described, one-fourth as sodium cyanid and about an equal amount as ammonium sulphate.

History of the fertilizer industry, J. RUHM, Jr. (*Bien. Rpt. Tenn. Dept. Agr., 1903-4, pp. 205-217, fig. 1*).—A brief general summary of the history of the phosphate industry in Tennessee, containing also notes on geology, location and description, and mining of the phosphates.

The chemical fertilizer industry, L. SCHUCHT (*Die Chemische Düngemittelindustrie. Brunswick: Friedrich Vieweg & Son, 1906, pp. VII + 164, figs. 27*).—This is practically a summary intended for young chemists of the author's earlier work on the manufacture of superphosphates, the second edition of which was published in 1903. It deals with the preparation of bone meal for fertilizing purposes, superphosphates, double superphosphates, Thomas slag, dicalcium phosphate, industrial by-products, and atmospheric nitrogen, and gives methods of analysis of fertilizers, with various tables useful in connection with such work.

Commercial fertilizers, A. Goss and W. J. JONES, Jr. (*Indiana Sta. Bul. 112, pp. 135-208*).—This bulletin gives the text of the State fertilizer law, with explanations as to how the law is administered and terms used in fertilizer

analyses, statistics of fertilizer sales in different sections of the State, and results of analyses of 308 samples of fertilizers collected during the spring of 1905 and 426 samples collected in the fall of 1905.

Analyses of commercial fertilizers, M. A. SCOVELL ET AL. (*Kentucky Sta. Bul.* 123, pp. 191-223).—Analyses and valuations of 151 samples of fertilizers inspected during 1905 are reported.

Analyses and valuations of fertilizers, J. P. STREET, W. P. ALLEN, and V. J. CARBERRY (*New Jersey Stat. Rpt.* 1905, pp. 15-76).—This is a reprint of matter contained in Bulletins 187 and 188 of the station (E. S. R., 17, pp. 450, 846), with the addition of a list of manufacturers whose goods were sampled and analyzed during 1905, and data relating to the wholesale prices of fertilizing materials in New York during different months of the year 1904 and valuations for 1905.

Fertilizer analyses, fall season, 1905, and spring season, 1906, B. W. KILGORE (*Bul. N. C. Bd. Agr.*, 27 (1906), Nos. 3, pp. 48; 4, pp. 48).—The names and guaranteed composition of fertilizers registered for 1906, and analyses and valuations of 230 samples of commercial fertilizers and 39 samples of cottonseed meal, examined during the fall of 1905 and spring of 1906, with explanations regarding terms used in fertilizer analyses, freight rates, valuation, etc.

Analyses of commercial fertilizers (*Bien. Rpt. Tenn. Dept. Agr.*, 1903-4, pp. 37-77).—The results of fertilizer inspection in the State during 1903 and 1904 are reported, with the text of the State fertilizer law and the rules and regulations adopted in accordance with the law.

Standard fertilizers, 1906, T. MACFARLANE (*Lab. Inland Rec. Dept. [Canada] Bul.* 118, pp. 19).—Analyses of 153 samples of fertilizers inspected during the year are reported and briefly discussed. Attention is called to an apparent tendency toward increased use of low-grade fertilizers, and it is pointed out that this is poor economy.

Fertilizers, J. A. VOELCKER (*Jour. Roy. Agr. Soc. England.* 66 (1905), pp. 153-159).—Analyses of slag, steamed bones, soot, lime, mustard cake, poultry manure, feather waste, and other barnyard manures are reported and briefly commented upon. Nitrogen (2.19 and 3.72 per cent) and siliceous matter (51.36 and 19.34 per cent) in 2 samples of soot are reported. The first, as the analysis shows, was fully one-half ashes and similar matter, while the second is considered of good quality.

Analyses of one sample each of poultry manure and feather waste are reported. The poultry manure contained 62.5 per cent of water, 0.83 per cent of lime, 2.13 per cent of "alkalis, etc.," 0.65 per cent of phosphoric acid, and nitrogen equal to 1.93 per cent of ammonia; the feather waste contained 9.12 per cent of water, 1.25 per cent of lime, 2.74 per cent of "alkalis, etc.," 1.4 per cent of phosphoric acid, and nitrogen equal to 12.08 per cent of ammonia.

The use of chemical fertilizers in Belgium during the decennial period 1895-1905, M. BERGER (*Rev. Gén. Agron., n. ser.*, 1 (1906), No. 3, pp. 98-101).—The consumption of unmixed fertilizers in Belgium in 1904 is stated to be 307,676 metric tons (2,200 lbs.), an increase of 83.8 per cent over that of 1903. The consumption of mixed fertilizers was 70,002 metric tons, an increase of 4.6 per cent over that of 1903.

Production and commerce in basic slags in Belgium (*Rev. Gén. Agron., n. ser.*, 1 (1906), No. 3, pp. 127, 128).—This is a brief review of a report published by the Minister of Public Works of Belgium, showing that this country produces about 225,000 tons of Thomas slag annually, 210,000 tons of which is ground for use as fertilizer. About three-fourths of the total product of the country is exported to foreign countries. The slag contains on an average 18 to 20 per

cent of phosphoric acid and is ground so that not less than 75 per cent of it will pass a sieve having 0.17 mm. meshes.

AGRICULTURAL BOTANY.

Agricultural botany, E. SCHREIBAU and J. NANOT (*Botanique Agricole. Paris: J. B. Baillière & Sons, 1906, pp. XI + 376, figs. 294*).—This work, which is a part of the Agricultural Encyclopedia issued by the publishers, is a general treatise on the subject of botany, in which the morphology, physiology, anatomy, etc., of the different parts of plants are described, and special chapters are given on the preservation of agricultural products, their improvement by breeding and selection, etc.

Native economic plants of Montana, J. W. BLANKINSHIP (*Montana Sta. Bul. 56, pp. 38*).—The object of this bulletin is to enumerate, so far as possible, the native plants of the State utilized by the Indians, the early explorers, trappers, and settlers, as well as to mention the chief species now employed in our own industrial life. The lists are given arranged alphabetically according to the scientific names. Additional lists are given grouped according to their use in various arts, as foods, medicines, etc.

Report of the botanist, H. L. BOLLEY (*North Dakota Sta. Rpt. 1905, pp. 23-32*).—The investigations of the botanist have been confined largely to studies on wheat, flax, potatoes, grass, and native plants, breeding and selection for resistance being prominent items in his work.

Attention is called to some of the results of selection for resistance to wheat rust, and the discovery of uredo and teleutospores in the grains of shriveled samples of durum and fife wheats is noted. Thus far attempts to propagate the rust from these infested grains have failed, but the occurrence of these spores in the seed is believed to offer a possible explanation for the wintering of the rust.

In connection with the author's studies on the wilt of flax, immune strains have been found that seem to be quite resistant to the wilt, but during the season's observations it was found that these plants were especially attacked by a form of rust (*Mcclumpsova lini*). So severe was the rust that in some instances the flax plants were almost completely destroyed. It has already been observed that some sorts of flax are more resistant to rust than others, and in the future investigations will be carried on for immunity both to rust and wilt.

Some notes are given on potatoes, and the variation of some varieties and of individual plants in resisting disease is pointed out.

A brief account is given of the use of commercial cultures in inoculating legumes, and in the experiments no distinction could be drawn between the treated and the untreated plats.

The tree-feeding experiments, which have been described in previous reports (E. S. R., 16, p. 131; 17, p. 261), were discontinued in 1905 on account of other work, but some observations made showed that the native plum trees which had been treated for the prevention of plum pockets were less attacked than untreated trees in the immediate vicinity. Trees treated for apple blight in 1904 remained healthy during 1905 and produced fruit.

Further observations on the germination of the seeds of the castor-oil plant, J. R. GREEN and H. JACKSON (*Proc. Roy. Soc. [London], Ser. B, 77 (1905), No. B 514, pp. 69-85*).—The results of a series of investigations extending back about 15 years in which the authors endeavored to ascertain the course of the decomposition and utilization of the reserve materials in the seed of the castor-oil plant during germination are given.

Various conclusions are drawn from earlier experiments, which are modified somewhat, and the authors state that the germination of the seed of castor bean is associated with a remarkable activity of the cells of the endosperm, which set up a very complex metabolism. The protoplasm takes a prominent part in the metabolic changes produced, secreting enzymes, and causing various chemical changes in the cells. In this renewed activity the embryo contributes to enzyme formation, and the result is the production of a great variety of nutritive material, part of which is the direct product of enzyme action and part is due to the secretory activity of the protoplasm as well as to the interaction of the products of both these agents. Two varieties of sugar, lecithin, fatty acids and the products of their oxidation, proteids and the products of their digestion, including various nitrogenous bodies, amino-compounds, and amido-compounds are present. Analyses of the cotyledons showed them to contain varying quantities of lecithin, in some cases amounting to 1.36 per cent of their dry weight. Both sugars may be detected in the cotyledons, the relative amounts varying, but cane sugar being usually present in the largest quantity.

The reaction of the cell sap is acid, showing traces of phosphoric acid mixed with an organic acid whose nature has not yet been ascertained. It is probable that in the transportation of the nutritive substances to the embryo the protoplasmic threads in the cell walls play an important part, and dialysis undoubtedly plays a large part in the absorptive processes, especially where crystalline substances are concerned.

On stimulants of nutrition in plants, II. MICHEELS (*Rev. Sci. [Paris]*, 5, ser., 5 (1906), No. 14, pp. 427-429).—Experiments on the influence of solutions of colloidal tin on the germination and early growth of wheat, oats, peas, buckwheat, etc., are reported, showing that this substance has a very marked influence in promoting germination and growth. It apparently acts upon the reserve material of the seed in much the same manner as diastase or other ferments.

On the nature of the galvanotropic irritability of roots, A. J. EWART and JESSIE S. BAYLISS (*Proc. Roy. Soc. [London]*, Ser. B, 77 (1905), No. B 514, pp. 63-66).—The authors review and attempt to explain the contradictory statements of a number of investigators on the nature of the galvanotropic irritability of roots, after which they briefly describe some experiments which tend to show that the galvanotropism of roots is due to chemotropic stimulation by the products of electrolysis, of which the acid is more effective than the alkali. It is claimed that in Brunchhorst's experiments, which seem to show that strong currents produced a curvature toward the positive electrode and weak ones toward the negative electrode, the electrolysis probably occurred in the superficial cells of the roots submerged in water, the tissues being sufficiently impermeable to the liberated acid and alkaline ions to allow them to accumulate beyond the minimum for stimulation. Although the curvature is usually sharp and strongly localized to the point of application of the electrode, the indications are that the response is a stimulatory one and is not due to the direct action of the products of electrolysis, retarding growth on one side or accelerating it on the other.

The action of certain organic substances on the form and structure of leaves, M. MOLLIARD (*Bul. Soc. Bot. France*, 53 (1906), No. 1, pp. 61-65).—Experiments are reported that were conducted to determine the relation which exists between the structure of some of the higher plants and the organic medium in which they were grown. All the experiments were with radishes, one lot being grown in mineral solutions, the others in various forms of carbohydrates. The growth in the mineral solutions was comparable with that of plants grown under normal conditions, but when grown in solutions of saccharose, glucose, levulose, dextrin, etc., the morphological structures showed marked departures

from normal. The color, size, form, and structure of the leaves were greatly modified by the different carbohydrates, and in some cases the changes were in proportion to the strength of the solutions. Saccharose intensified the coloration, reduced the size of the leaves, and modified their contour. Glucose reduced the size of the leaves, their margins were more deeply dentated, and very important changes were noted in their structure, especially in the palisade tissues. Mannite and glycerin modified the leaves so greatly as to indicate an injurious action.

The growth of chlorophyll bearing plants in amids in the absence of carbon dioxid, J. LEFÈVRE (*Compt. Rend. Acad. Sci. [Paris], 141 (1905), Nos. 3, pp. 211-213; 17, pp. 664, 665; 24, pp. 1035, 1036*).—An account is given of experiments with common garden cress, nasturtiums, and sweet basil grown in artificial soils to which various media were added, but with the entire exclusion of carbon dioxid. The seedlings were placed in pots filled with crushed silica that had been washed with acid and incinerated, sterilized artificial moss being mixed with it to give proper consistency. To each 350 gm. of the artificial soil there were added 0.1 gm. each of tyrosin, oxamid, and leucin, and 0.4 gm. of glycocoll and alanin. The plants were placed under bell jars and kept free from carbon dioxid by passing all air through Schloesing baryta tubes. Numerous check pots were maintained, and the results in all cases were analogons.

It was found under the conditions of the experiments that the plants grew in the absence of carbon dioxid, increasing their height 5 to 10 times, with a corresponding increase in the number of leaves. When both carbon dioxid and amids were excluded, no growth resulted and the plants speedily died. It is claimed that the growth was due to actual nutrition of the plants and not to artificial hydration.

The results show that in the light, green plants are able to carry on synthesis in the presence of amids and in the exclusion of carbon dioxid. This synthesis is held to be a function of chlorophyll.

On the water relations of the cocoanut palm, E. B. COPELAND (*Philippine Jour. Sci., 1 (1906), No. 1, pp. 6-57, pls. 3*).—An investigation was inaugurated to determine, through a study of the physiology of the cocoanut palm, results that would be available for improving existing methods of the cultivation of the plant. The investigations are reported upon in the following order: The root, its structure and growth, and the absorption of water; the leaf, its structure, the activity of the stomata, and transpiration; with final conclusions as to the fitness of the plant for its characteristic habitat and suggestions as to its most advantageous cultivation.

Among the practical conclusions, the author states that a considerable supply of water must constantly be at the disposal of the tree, or it will protect itself against injurious desiccation by a partial suspense of its vitality. The quantity of mineral food which the tree takes is roughly proportional to the amount of water which it absorbs, and by increasing the plant's transpiration the same results are obtained as would follow the application of fertilizers to the ground. The amount of transpiration can be increased either by increasing the amount of water at the disposal of the roots or by improving the conditions for its evaporation from the leaves. The transpiration of the cocoanut is accelerated by the action of the wind, and to a still greater extent by increase of illumination. In planting the trees the author doubts whether any increase beyond 15 meters' distance between trees would be advantageous. In his opinion, under ordinary conditions trees in a grove usually do best when placed at intervals of about 9 meters. In order to secure increased yield, the author suggests better cultural methods and improvement through the selection of the seed used in planting.

FIELD CROPS.

Results of cooperative experiments in agriculture, C. A. ZAVITZ (*Ann. Rpt. Ontario Agr. and Expt. Union, 27 (1905), pp. 12-33*).—A description of these experiments is given in connection with previously reported results (E. S. R., 17, p. 351). In the cooperative experiments in the season of 1905 the leading varieties of grain crops gave the following average yields per acre: Joannette oats, 120 tests, 53.58 bu.; Mandscheuri Six-rowed barley, 28 tests, 37.73 bu.; Black Hulless barley, 13 tests, 24.63 bu.; Wild Goose spring wheat, 24 tests, 34.87 bu.; Common emmer, 19 tests, 39.94 bu.; Red spelt as compared with emmer, 31.90 bu.; Japanese buckwheat, 7 tests, 37.50 bu.; Early Britain field peas, 19 tests, 28.32 bu.; New Prize Winner field beans, 20 tests, 27.21 bu.; Early Yellow soy beans, 2 tests, 18.33 bu.; Dawson Golden Chaff winter wheat, 14 tests, 23.16 bu.; and Compton Early corn, 17 tests, 56.74 bu. The best and most popular mixture of grains consisted of 34 lbs. of Daubeney oats and 48 lbs. of Mandscheuri barley, which produced on the average in 11 tests 2,073 lbs. of grain per acre. In all cases except one the varieties here mentioned ranked first in popularity with the experimenters. Joannette oats stood second in this regard.

The leading varieties of field roots and fodder crops gave the following yields per acre: Yellow Leviathan mangels, 8 tests, 33.57 tons; Giant White Feeding sugar beets, 7 tests, 35.65 tons; Sutton Magnum Bonum swede, 2 tests, 18.04 tons; Red Top White Globe fall turnips, 2 tests, 34.53 tons; Mastodon White Intermediate carrots, 8 tests, 24.56 tons; Henderson Eureka fodder corn, 7 tests, 17.48 tons; Japanese Panicle millet, 2 tests, 16.72 tons, and Dwarf Essex rape, 1 test, 17.82 tons. In 3 tests grass peas, common vetches, and hairy vetches gave 10, 8.93, and 8.65 tons per acre, respectively. Nearly all these varieties were the most popular with the experimenters, excepting Henderson Eureka fodder corn, which was outranked by White Cap Yellow Dent, and grass peas, which ranked next to the vetches.

Three varieties of sweet corn, Ringleader, Mammoth White Cory, and Golden Bantam, requiring 84, 87, and 88 days, respectively, to mature for table use, were grown in 21 tests. In comparative value Ringleader stood first and in table quality Golden Bantam. The average results for 6 years in 38 tests show that corn in hills gave an average of 11 tons of whole crop as compared with 10.16 tons for corn planted in drills.

In the fertilizer experiments conducted as in previous years, the greatest yield of total crop of corn was secured from the use of muriate of potash and the greatest yield of husked ears from the complete fertilizer. An application of 160 lbs. of muriate of potash per acre increased the yield 1.5 tons at a cost of about \$3 per ton for the fertilizer used. The best yield of swedes, 23.1 tons per acre, was secured where barnyard manure was applied. In 41 tests during 5 years the best average yield of mangels, 26.5 tons per acre, was obtained with nitrate of soda, and during this same period in 74 experiments the highest average yield of oats, 48.7 bu. per acre, was secured with the complete fertilizer.

In 1905 the average yields of 3 late varieties of potatoes, Dempsey Seedling, Empire State, and American Wonder, grown in 93 tests, were, respectively, 177.1, 160.3, and 159.4 bu. per acre. Of 2 medium varieties grown in 70 tests, Rose of the North stood first with 184 bu. per acre, while among early varieties in 158 tests Early Fortune headed the list with 167.4 bu. Dempsey Seedling, Rose of the North, and Early Fortune ranked first in popularity in their respective classes. The average results of 33 tests for 5 years show a slight advantage in growing potatoes on ridges as compared with growing them on the level.

The Woburn field experiments, 1904, J. A. VOELCKER (*Jour. Roy. Agr. Soc. England, 66 (1905), pp. 192-205*).—Earlier results have been previously noted (*E. S. R.*, 17, p. 543). In the continuous wheat-growing experiments the largest yield this year, 17.1 bu. per acre, was secured from the plat receiving in alternate years, including 1904, $3\frac{1}{2}$ cwt. of superphosphate of lime, 200 lbs. of sulphate of potash, 100 lbs. each of sulphate of soda and sulphate of magnesia, with nitrate of soda sufficient to furnish the quantity of nitrogen contained in 100 lbs. of ammonia per acre. The injurious effect of the continued use of ammonia salts and nitrate of soda was strongly shown this year with a rainfall of only 22 in. The effect of 2 tons of lime applied in December, 1897, was still noticeable this season. Where nitrate of soda was omitted for a single year the yield fell below that of the unmanured plat. In quality of grain the barnyard manure plat ranked with the best, while the nitrate of soda plat stood last.

The highest yield of barley, 37 bu. per acre, was secured with a heavy dressing of nitrate of soda and minerals. As with wheat, the continued use of ammonia salts showed its injurious effects, while lime proved beneficial. In the green manuring experiment mustard plowed in with mineral manures gave better results with both quantity and quality of barley than tares used in the same way.

Of 2 Canadian wheats compared Red Fife yielded 20.2 bu. and Preston 12.6 bu. per acre. Both varieties produced grain of high quality.

The use of 4 cwt. each of superphosphate, bone dust, and sulphate of potash, and 2 cwt. of sulphate of ammonia per acre for alfalfa gave a yield of more than $9\frac{1}{2}$ tons of hay. Where 2 cwt. of nitrate of soda was substituted for sulphate of ammonia the yield was a little over 8.3 tons, while single applications of these substances gave in all cases less than 4 tons per acre.

English common sainfoin proved more satisfactory than English Giant, and both gave much heavier yields than the French Giant and common varieties. Sulphate of potash gave better results as a fertilizer for potatoes than kainit.

In the finger-and-toe experiments on swedes 2 tons of carbolized lime per acre was the only application which produced no unsound roots.

The Woburn pot-culture experiments, 1904, J. A. VOELCKER (*Jour. Roy. Agr. Soc. England, 66 (1905), pp. 205-211*).—A report on the Hills experiments is given. The results of this year indicate that the use of solutions of sulphate of manganese and sulphate of iron not over 2 per cent in strength, improves the germination of seed grain. Soaking wheat in solutions of sulphate of manganese gave no appreciable increase in grain and straw, while soaking in a 2 per cent or 5 per cent solution of sulphate of iron produced a gain in total yield. It is concluded that solutions of sulphate of manganese up to 2 cwt. per acre, applied directly to the growing plant, increased the yield and that sulphate of iron used at the rate of one-half or 1 cwt. per acre has a similar effect. Silicates of potash and soda did not improve germination, but when given at least at the rate of 4 cwt. per acre were beneficial, especially in improving the yield of straw.

The germination of barley was not injured by soaking in these solutions. The use of a solution of sulphate of manganese up to a strength of 5 per cent was of some benefit, while soaking in a solution of sulphate of iron did not injure germination, but was not productive of any improvement. These solutions applied directly to the growing plant produced some increase of crop. Silicates of potash and soda benefited the crop, especially the straw.

[Report on the] subsection of agronomy, W. H. OLIN (*Colorado Sta. Rpt. 1905, pp. 24-36*).—The work of the season consists of field nursery work, testing of grains and forage plants, cooperative field work, and sugar-beet investiga-

tions. Of 9 varieties of barley grown Hanchion and U. S. No. 12023, both 2-rowed varieties, headed the list in yield with 59.6 and 53.4 bu. per acre, respectively. The barleys were grown on alfalfa sod, which encouraged a rank growth and a tendency to lodge. Of 16 varieties of wheat Colorado No. 45 and Colorado No. 50 were the earliest, ripening the first week in August. Minnesota No. 169 ripened last. The grain of this variety was only in the milk when the grain of the two varieties mentioned above was in the dough stage. Kubanka sown in April and May was not seriously injured by rust, but Defiance, sown at the same time, suffered from this disease and lodged very badly before it was fully ripe. Sonora was more severely attacked by rust than any other variety. The results of seedings made at intervals of about 1 month from January to June seemed to indicate that the earlier seedings are the more satisfactory. In connection with milling wheat investigations it was found that, in the opinion of the millers, Defiance is the best spring wheat and Turkey Red the best winter wheat for milling purposes. Baking tests by over 40 experienced bread makers of Fort Collins showed that the flour of durum wheat produces bread of an excellent flavor and of good texture and volume.

Among 10 varieties of oats Early Champion and U. S. No. 12303 ripened earliest and produced the finest straw. The most productive varieties were White Russian, Kansas No. 2, and Colorado No. 13, yielding 93.1, 92.8, and 92.4 bu. per acre, respectively. Colorado No. 5, the heaviest variety, produced grain weighing 47 lbs. per bushel.

Cooperative field work with farmers in different sections of the State and the sugar-beet investigation work conducted by the station are briefly noted.

Report of the agriculturist, J. J. VERNON (*New Mexico Sta. Rpt. 1904*, pp. 24-27).—A brief description of the work of the department with field crops is given and some of the results are reported. Twenty-four varieties of wheat were tested, the yields ranging from 57.5 bu. per acre for Rodi to 15.8 bu. for Ruby. Ruby also stood last in the yield of straw with 1,486.8 lbs. per acre, while Defiance stood first with 7,973 lbs.

For the purpose of determining the best means of incorporating humus in the soil 1 plat received a heavy coating of stable manure, 1 was sown to cowpeas, and 1 to hairy vetch. These were compared with a spring-plowed plat and a check plat which were cropped as usual. The cowpeas and the hairy vetch had made a very rank growth when they were plowed under. The largest yield of corn stover was secured on the cowpea plat, the largest yield of barley straw on the manure plat, of oat straw on the hairy vetch plat, and of wheat straw on the cowpea plat. In grain production the manure plat stood first in the yield of corn and barley, while the hairy vetch plat ranked first in the yield of oats and the spring-plowed plat in the yield of wheat.

[**Report on field crops**], J. H. SLEPPARD (*North Dakota Sta. Rpt. 1905*, pp. 33-46, pls. 5).—A general outline of the work during the year is given, together with more detailed notes on the plant-breeding work and the results of experiments with red clover and alfalfa.

Twenty samples of red clover from different States and countries are under test in a cooperative experiment with this Department. The yield of cured hay ranged from 1.87 to slightly more than 3 tons per acre. The clover was sown with life wheat as a nurse crop in the spring of 1904. On August 2 after the wheat had been mown for hay the seed from Missouri, eastern Ohio, and Russia showed the best stand and most thrifty appearance, with the seed from Illinois and Wisconsin about as good. October 5 the seed from Illinois and Wisconsin had the best general appearance. The second growth was ready for cutting about September 10, 1905, and the yields secured during the year are regarded as positive evidence that with proper treatment red clover can be

successfully grown in the Red River Valley. At the time of the second cutting one-half of each plat was left to produce seed. The highest yield secured was 2 bu. 26 lbs. It was observed during this season that a clover seeding made in the spring with wheat as a nurse crop did not suffer as much from heavy rains as alfalfa.

Alfalfa sown in 1901 and 1902 after 3 and 4 winter seasons still makes vigorous growth. On June 27 of this year, when the first crop was cut, the Turkestan variety was 36 in. high and formed 90 per cent of a stand, giving a yield of 2.37 tons per acre. The second growth, which was as heavy as the first, was allowed to ripen seed. Grimm alfalfa as compared with Turkestan had finer stems and produced more branches and leaves. The first cutting of Grimm alfalfa gave a yield of 3.24 tons per acre.

Forage crops, 1905, G. A. BILLINGS (*New Jersey Stat. Rpt. 1905, pp. 349-376, pls. 10*).—The summer system of soiling was continued as in previous years (E. S. R., 17, p. 353). With the exception of two weeks in July, summer forage crops were fed to the station herd from May 1 to October 15, a period of 153 days. The average cost of production was \$1.93 per ton and the average yield on 16 acres 12.3 tons per acre.

In this connection a series of forage crop rotations was studied. This included 1 plat of corn for silage, 1 plat of wheat and winter vetch for the first crop and white flint corn for the second crop, and 1 plat of alfalfa for hay. A plat of oats and vetch and 1 of millet suffered from dry weather, while oats and peas began to mature when the dry weather set in and produced an average yield. Five plats gave an average yield of 14.8 tons of forage per acre, while 3 gave an average yield of only 7.3 tons. Excellent results were secured on the plat on which wheat and winter vetch were followed by corn. The wheat and winter vetch produced 7.10 tons of forage per acre and the flint corn 108.7 bu. of ears and 5.6 tons of dry fodder. It is stated, however, that the high price of vetch seed makes its profitable use doubtful. General notes on rye, wheat, winter vetch, crimson clover, and alfalfa are given.

Inoculation experiments were made, but weather conditions interfered with the accuracy of the results. The inoculating material consisted of 450 lbs. of soil from an old alfalfa field and the same quantity from a field of sweet clover. The plats so treated were compared with a plat receiving no inoculation and one inoculated the previous year. Before inoculation the land received 200 lbs. of oyster-shell lime and about 300 lbs. of fertilizer per acre. The examination of the roots on all plats showed the nodules equally abundant. They were most numerous where the soil was deep and the foliage green and thrifty. On yellow spots with less thrifty plants the nodules were found in more compact masses than where the plants were green. An examination by the station bacteriologist showed that these masses also contained more of the branched forms of bacteria, which are usually found on healthy, vigorous plants, but in this case seemed so abundant on the sickly ones. This condition was not due to lack of nitrogen, as an application of nitrate of soda at the rate of 100 lbs. per acre showed no beneficial effect. This clustering of the nodules is considered as possibly due to the ventilation of the soil or its porosity, soil acidity, or different bacteria entering in to influence the form of the nodules. The results secured do not admit of giving definite conclusions, but it is suggested that some time previous to seeding organic matter be incorporated into the soil by a liberal application of barnyard manure or green manuring, and that an application of at least 2,000 lbs. of stone lime be given at the time of seeding, or preferably, 2,000 lbs. a year or two before seeding and 1,200 lbs. at the time the seed is sown.

Cylinder experiments were made with lime for alfalfa on different types of soil. These soils were benefited by the lime in the following order: Augusta limestone, Freehold marl, New Brunswick red shale, Oakland glacial drift, Woodstown heavy clay, and Woodbine sand. In another test it was shown that nitrate of soda applied in June, July, and August did not increase the yield. In this test the use of 300 lbs. of acid phosphate and 200 lbs. of muriate of potash gave an increased yield of only 4.1 per cent over the use of 200 lbs. of acid phosphate and 150 lbs. of muriate of potash.

Thoroughbred white flint corn planted July 19 yielded 8.25 tons of green forage per acre, and a mixture of 12 qts. of Kafir corn and 1½ bu. of cowpeas, sown broadcast, per acre, gave a yield of 11.3 tons. Twelve varieties of cowpeas were compared and notes on the habit of growth and the yields are given. Clay ranked first in the production of green forage, with 8.3 tons per acre, and Warren New Hybrid in the production of seed, with 13.3 bu. In a test of 4 varieties of soy beans Medium Yellow No. 12399 stood first in production of both green forage and seed, the yields being 6.9 tons and 24.5 bu., respectively. The average cost of producing a ton of hay from 10 acres of oats and peas was \$7.91, the average yield per acre being 2.15 tons. Four varieties of corn grown for the silo produced a ton of forage at an average cost of \$1.14, the range being from \$1.10 to \$1.19. Southern White stood first in yield, with 9.7 tons per acre. A comparison of soiling and silage crops showed that corn silage cost per ton 18 cts. more than soiling crops.

Nitrate of soda proved profitable when applied as a top-dressing to rye, but on wheat and vetch it was used at a loss. It is stated that this substance should be applied only on cereals and grasses very early in the spring.

Observations and experiments on clover, alfalfa, and soy beans, H. GARMAN (*Kentucky Sta. Bul. 125, pp. 37-61, pl. 1, fig. 1*).—Soil inoculation for leguminous crops is discussed and results obtained in experiments along this line are reported. The failures in growing leguminous plants—are considered due to poor seed, insufficient humus content of the soil, inadequate soil preparation, weeds, plant diseases and insect enemies, and the absence of lime, potash, or other mineral elements. The results of investigation with these different crops indicate that clover should be grown on clean land containing some humus and alfalfa on good land not too wet. Both crops give best results from spring planting on well-prepared land, the seed being worked in with a drag or harrow. Inoculation with cultures or soil did not help the stand of either clover or alfalfa, and nodules are developed on both plants in Kentucky soils without inoculation, although this treatment may increase the number of nodules in any soil. Inoculation of the seed failed to increase the yield of the leguminous plants, but it is believed that the benefit from inoculation in these particular soils falls largely to the succeeding crop. It was observed that the nodules were large when few and small when numerous, and that fresh moist cultures are better than dry ones.

Culture tests in 1904 and 1905, A. DAMSEAUX (*Bul. Agr. [Brussels], 22 (1906), No. 1, pp. 54-61*).—Experiments were made with cereals, root crops, and various other forage plants. The results of fertilizer experiments with sugar beets, in which 300 and 500 kg. of salt was applied in conjunction with 500 kg. each of superphosphate and nitrate of soda per hectare, showed that the use of the salt increased the yield of sugar. The largest yield of roots and leaves of carrots was obtained on a plat where 20,000 kg. of barnyard manure, 500 kg. of superphosphate, and 200 kg. each of sulphate of potash and nitrate of soda were applied per hectare. This plat produced 72,100 kg. of roots and 12,500 kg. of leaves, furnishing 8,940 kg. of dry matter per hectare.

The manurial value of different potassium compounds for barley and rice, K. Aso (*Bul. Col. Agr., Tokyo Imp. Univ., 7 (1906), No. 1, pp. 67-72*).—It was found that potassium chlorid accelerated the flowering process and augmented grain production in barley, while it reduced the yield of rice. The fertilizer value of the silicate was highest in several cases and martellin is regarded as a good potash fertilizer for grasses. The chlorid acted very favorably on the production of grains, while the sulphate tended to increase the formation of straw. The carbonate was inferior to the sulphate in all cases when applied with secondary sodium phosphate, a physiologically alkaline manure.

On the influence of the reaction of the manure upon the yield, K. Aso and R. BAHADUR (*Bul. Col. Agr., Tokyo Imp. Univ., 7 (1906), No. 1, pp. 39-46, pl. 1*).—Different combinations of plant food substances were used in sand with rice, peas, and barley, and soil culture with onions and barley. The influence of the reaction of the manuring compounds was observed to be very great. The combination of ammonium sulphate and disodium phosphate produced the best results with paddy rice, while the mixture of sodium nitrate and monosodium phosphate gave the best results with barley and peas. In the test with onions ammonium sulphate produced a much better result than sodium phosphate when phosphoric acid was given as disodium phosphate and potash in the form of potassium carbonate.

On the lime factor for flax and spinach, S. NAMIKAWA (*Bul. Col. Agr., Tokyo Imp. Univ., 7 (1906), No. 1, pp. 57-60*).—The lime factor is here determined as the best ratio of lime to magnesia, and the results secured show that this factor for flax and spinach is about equal to 1.

Plowing experiments, W. FARRER and G. L. SUTTON (*Agr. Gaz. N. S. Wales, 17 (1906), No. 4, pp. 319-326, fig. 1, dgms. 2*).—In connection with experiments with wheat at the Cowra Experiment Station a comparison of disk and mold-board plows for preparing the soil showed that in new ground of a loamy character and during a wet fall and winter the use of the mold-board plow is preferable to the disk plow. The results obtained further indicate that it is much better to plow 6 in. deep with the mold-board plow than to plow only 4 in. deep; and when the work is done with the disk plow a depth of 8 in. seemed to give better results than shallower plowing.

Alfalfa, W. P. HEADDEN (*Colorado Sta. Bul. 110, pp. 16*).—This bulletin is a general and brief treatise on the culture of alfalfa in Colorado, the discussion being based largely on the subject-matter contained in Bulletin 35 of the station (E. S. R., 8, p. 768). Since the publication of that bulletin vitality and germination tests of alfalfa seed were made and the results are here briefly stated. It was determined that the first quality seed purchased in 1905 by the station contained 288,267 seeds per pound, while 2 samples of first quality screenings contained 259,340 and 266,233 per pound, respectively. Twelve samples of seed and screenings were kept for a series of years, the age of the samples in 1906 varying from 2 to 16 years, 11 of the samples being over 11 years old. The average percentage of germination in these samples ranged from 14 to 92.5. The sample averaging highest was 12 years old and had lost during this period only 2.5 per cent of its germinating power. Four other tests were made with this sample and the average of these 4 tests showed a germination of 94.25 per cent, or very nearly as high as in the test made in 1896 when the seed was only 2 years old. The results with this sample show that "good, plump, mature, clean alfalfa seed does not lose its vitality rapidly when kept with ordinary precaution to prevent injury from moisture." The oldest sample had a germinating power of 93 per cent when 6 years old, of 72 when 10 years old, and of 63 when 16 years old. The author believes that the limit for the

vitality of good, mature alfalfa seed exceeds 16 years. The variation between different lots of seed is shown in this test by the sample which was only 2 years old and had a germinating power of but 67.5 per cent. The seeds in this sample were small.

Alfalfa, W. P. HEADDEN (*Colorado Sta. Bul. 111, pp. 12*).—A synopsis of Bulletin 35 of the station (E. S. R., 8, p. 768).

The alfalfa seed crop and seeding alfalfa, A. M. TEN EYCK (*Kansas Sta. Bul. 134, pp. 111-131*).—This bulletin presents the experience in saving alfalfa for seed as described by several hundred prominent alfalfa growers throughout the West, but mainly in Kansas. In this way complete directions are given for growing alfalfa for seed and also for seeding the crop and obtaining a good stand.

Alfilaria (Erodium cicutarium) as a forage plant in Arizona, J. J. THORNBERR (*Arizona Sta. Bul. 52, pp. 23-58, figs. 5, map 1*).—The introduction and dissemination of alfilaria in Arizona is discussed, the botanical characters of the plant described, and the factors favoring its growth in the Southwest are pointed out. Chemical analyses of two samples by A. E. Vinson, of the station, resulted in the following data for alfilaria in seed: Moisture content 81.53 per cent, ash 3.52, protein 2.38, crude fiber 4.46, nitrogen-free extract 7.82, and ether extract 0.39. Good alfilaria hay contained 8.88 per cent of moisture, 13.30 per cent of ash, 13.49 per cent of protein, 20.55 per cent of crude fiber, 41.58 per cent of nitrogen-free extract, and 2.20 per cent of ether extract. Directions for collecting and sowing the seed are presented. It is shown that sheep have been very instrumental in spreading the plant.

On the formation of anthokyan in the stalk of barley, S. SUZUKI (*Bul. Col. Agr., Tokyo Imp. Univ., 7 (1906), No. 1, pp. 29-37*).—The author observed in pot experiments that the red coloration shown in stalks of certain barley plants was due to anthokyan. Plants manured differently produced good stalks of a normal green color. Experiments were made on a sandy soil of great natural fertility and on a loam of poor fertility. Different combinations of fertilizers were applied. The data secured led to the conclusion that formation of anthokyan in the stalks is a sign of deficiency in the soil of available phosphoric acid or nitrogen, or of both these elements.

The influence of distance between plants on the quantity and quality of fodder beets, G. FRÖLICH (*Fühling's Landw. Ztg., 55 (1906), No. 8, pp. 264-269*).—Distance experiments were conducted for several years with fodder beets and the results indicated quite clearly that narrow planting produced not only a larger quantity of beets and an increase in food material, but also favored the production of healthier and better-formed beets with improved keeping qualities. The author recommends planting the Friedrichswerth fodder beet in rows 14 in. apart, leaving the plants at intervals of 9 in. in the row.

Clovers and how to grow them, T. SHAW (*New York: Orange Judd Co., 1906, pp. 349, pl. 1, figs. 11*).—A general description of the clover plant is given and popular directions for the growing of clovers are presented. An entire chapter is devoted to each of the more important varieties and species. In this list are included medium red, alsike, Mammoth, crimson, white, Japa, burr and sweet clovers, and alfalfa. A number of miscellaneous varieties of lesser importance, including sainfoin, Egyptian clover, yellow clover, sand lucern, Japanese clover, and beggar weed are briefly noted.

Cotton industry in the Leeward Islands, F. WATTS (*West Indian Bul., 7 (1906), No. 1, pp. 30-35*).—The growth of the cotton industry in the islands since 1900, when the present movement was begun by planting a small plat at the Antigua Experiment Station, is described. In 1904, 3,560 acres, and in 1905

approximately 5,000 acres were grown. The results of fertilizer experiments show that commercial fertilizers are not yet necessary in cotton culture, and the author advises that the cotton seed be fed to stock and the land enriched by the use of the manure.

Report on manuring of hay, 1906, R. B. GREIG (*Aberdeen and No. of Scot. Col. Agr. Bul. 5, pp. 13, figs. 2*).—Results of cooperative fertilizer experiments in 1904 and 1905 are tabulated and briefly noted. It was shown that a complete fertilizer of nitrate of soda, superphosphate, and sulphate of potash given at the rate of about 4 cwt. per acre produced the largest crop and the largest profit in one application. Nitrogen was found essential and potash more necessary than phosphates. Superphosphate and basic slag were more useful than bone meal and ground Florida phosphates in the first year's application. Sulphate of potash and all the phosphatic manures showed considerable residual value.

Cultural methods for sugar beets, W. H. OLIN (*Colorado Sta. Bul. 109, pp. 12, figs. 3*).—This bulletin points out the progress made in the culture of sugar beets in the State and records the methods practiced by the most successful sugar-beet growers, as shown by question circulars sent to 1,000 farmers distributed over 3 beet-growing regions of Colorado. From the answers received it was found that 54 per cent of the growers practiced spring plowing, that usually early planting is best for yield and quality, and that nearly all those reporting used from 15 to 20 lbs. of seed per acre. The average space between the plants in the rows is 10.4 in., and the best average results were secured where the crop was cultivated 3 times. The average tonnage for 1904 is given as 17.4 tons, and for 1905 as 14.25 tons per acre. The average expense per acre is estimated at \$33.05. Various other brief statements regarding the culture of this crop are also given.

Progress of the beet-sugar industry in the United States in 1905, C. F. SAYLOR (*U. S. Dept. Agr. Rpt. 82, pp. 130, figs. 5*).—A general review of the beet-sugar industry for the year is given and discussions on the conditions favorable to the establishment of the industry, the culture of the sugar beet, climatic conditions, and farm and factory results, together with the probable future of the industry in this country by States are presented. Statistics of the sugar industry in the United States and the world at large are also given. Sugar-beet investigations in 1905 by the Bureau of Plant Industry of this Department are briefly described.

The total number of factories operating in 1905 was 52. Four were idle during the year, and in March, 1906, 12 factories were in building. A tabulated summary of the results for 1905 shows that a total of 307,364 acres of beets averaging a yield of 8.67 tons per acre were harvested. The total quantity of beets worked was 2,665,913 tons, producing 312,920.60 tons of sugar. The average sugar content of the beets was 15.33 per cent, the average purity coefficient 82.96, the average length of the campaign 76.6 days, and the estimated average extraction of sugar 11.74 per cent.

Reports from agriculturists at sugar factories show briefly how irrigation was practiced in connection with beet growing, and reports from State experiment stations summarize the recent experimental work carried on by these institutions.

The work in growing single-germ beet seed has reached a point where strains have been secured producing approximately 25 per cent of single-germ seed.

It is reported that during the year blight or leaf spot in the Eastern States and curly top in the Rocky Mountain and Pacific Coast areas did serious damage. It has been shown that the blight may be prevented by spraying with Bordeaux mixture. No definite cause for the curly top has as yet been worked

out. It was observed that this disease rarely occurs twice in the same place consecutively. The work in growing sugar-beet seed is described and the results secured in 1904, which are the latest complete returns at hand, are again given. Earlier work in this line has been previously noted (E. S. R., 17, p. 29).

The sugar industry of Natal, A. N. PEARSON and A. PARDY (*Natal: Dept. Agr. [1906], pp. 16, figs. 2*).—Historical notes on the sugar industry are given and its present position and prospects are described. Statistics of imports and exports of sugar and of the production in Natal, and the total consumption in South Africa are presented. The varieties of cane generally grown are enumerated and briefly noted and analyses of different canes are reported.

Report on the experimental work of the sugar experiment station for the year 1905, H. H. COUSINS (*Rpt. Jamaica Sugar Expt. Sta., 1905, pp. 140*).—Fertilizer, varietal, selection, and distillery experiments are reported. In the variety tests a yield of nearly 50 tons per acre was secured on 2 acres of seedling B 208. In the selection tests this variety also showed the most merit, giving a tonnage of 65.5 tons of canes per acre. Other varieties worthy of some attention as shown by results secured at Hope are D 1429, B 316, D 109, and D 95. Among Jamaica seedling canes resulting from naturally cross-fertilized seed grown in 1903, No. 30 gave an indicated yield of 74.4 tons per acre, equal to 20,955 tons of sucrose, and No. 22 gave a very rich juice containing 2.2 lbs. of sucrose per gallon.

The bulletin includes a report by C. Allan, fermentation chemist, on the manufacture of Jamaica rum.

Manurial experiments with sugar cane in the Leeward Islands, 1904-5, F. WATTS ET AL. (*Imp. Dept. Agr. West Indies, Pamphlet 42, 1906, pp. 47, figs. 4*).—As in former years, the results with plant canes were unfavorable to the use of commercial fertilizers, but with the ratoon crop the use of sulphate of ammonia and nitrate of soda was of benefit. The details of these experiments have been previously given (E. S. R., 17, p. 460).

Tobacco breeding experiments in Connecticut, A. D. SHAMEL (*Connecticut State Sta. Rpt. 1905, pt. 6, pp. 331-342, pls. 3, fig. 1*).—A general outline of the breeding work carried on by the station in cooperation with this Department is given and two new varieties produced by hybridization, known as the Cooley hybrid and the Brewer hybrid, are described in detail. The Cooley hybrid was obtained by crossing Havana seed with pollen from plants grown from Florida Sumatra tobacco seed, and the Brewer hybrid by crossing Connecticut Broadleaf tobacco with Cuban as the male parent.

Methods of testing the burning quality of cigar tobacco, W. W. GARNER (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 100, pt. 4, pp. 14, pls. 2, figs. 3*).—Complete descriptions are given of the methods of testing the burning quality of cigar tobacco by means of different kinds of apparatus. The general results obtained indicated that in order to secure a good burn a heavy filler should be wrapped with a comparatively heavy wrapper and a light-bodied filler with a light-bodied wrapper, and that of the three components the filler exerts the strongest influence on the evenness of the burn. It was also shown that the wrapper and binder strongly influence the character of the ash and that the binder very materially affects the ash of the wrapper.

Garlicky wheat, J. W. T. DRVEL (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 100, pt. 3, pp. 14, pls. 2*).—Experiments are reported in which garlic was removed from 3 lots of wheat by drying the samples artificially and then removing the garlic bulblets by means of cleaning machinery. The quantity of garlic by weight in the 3 lots, A, B, and C, was 2.17, 0.56, and 2.04 per cent, and the

average loss in weight due to the removal of garlic was 2.12, 0.50, and 1.88 per cent, respectively. Other results secured are shown in the following table:

Results in experimental drying and cleaning of garlicky wheat.

Sample mark.	Duration of drying.	Temperature of air current in drying.	Maximum temperature of wheat.	Water content of wheat.	Germination.
	<i>Hours.</i>	<i>Degrees F.</i>	<i>Degrees F.</i>	<i>Per ct.</i>	<i>Per ct.</i>
Lot A:					
Original sample				16.55	
Experiment No. 1	2½		136	8.94	
Experiment No. 2	4		140	5.87	
Lot B:					
Original sample				15.08	80
Experiment No. 3	3	153-158	155	7.92	83.5
Experiment No. 4	3½	153-158	145	6.88	85
Experiment No. 5	2½	155-108	138	8.48	79.5
Lot C:					
Original sample				16.20	82
Experiment No. 6	2½	113-154	149	8.20	83
Experiment No. 7	3	146-122	131	8.83	85

Lot A was increased in value by 17 cts. per bushel, equivalent to 28.6 per cent; Lot B by 30 cts., or an increase in its value of 54.5 per cent; and Lot C by 24.5 cts., or 40.8 per cent. In none of the experiments was all the garlic removed, but its quantity was reduced considerably more than was necessary to make the wheat grade as No. 2 Red. The cost of removing the garlic was 5½, 2¾, and 4½ cts. per bushel for Lots A, B, and C, respectively, as governed by the prices current at the time.

The origin of Rietti wheat, E. A. NOBBS (*Agr. Jour. Cape Good Hope*, 28 (1906), No. 5, pp. 675-677).—The history of Rietti wheat is given and its composition compared with that of hard, medium hard, and soft wheats.

Specimen pages of a pedigree register for cereal breeding purposes, W. DIX (*Mitt. Deut. Landw. Gesell.*, 21 (1906), No. 20, pp. 211-213).—Samples of the register forms are given and their arrangement, value, and use described in detail.

References to recent work in plant breeding, C. FRUWIRTH (*Jour. Landw.*, 54 (1906), No. 2, pp. 139-158).—About 40 references to books, bulletins, and articles treating of plant breeding are briefly given.

The Swedish plant breeding work at Svalöf, A. ULANDER (*Jour. Landw.*, 54 (1906), No. 2, pp. 105-124, pls. 6).—The methods of carrying on the work in plant breeding at this institution are briefly described. The author points out that the old so-called methodic selection did not give the results that were expected, and improvement of large numbers of individuals at the same time, even with the best equipment, does not lead to fixation and never to new varieties with good distinguishing characters. He believes that the improvement of agricultural plants must be based solely upon the laws of transmission and variation in the individual. The work must be conducted on a purely scientific basis and only morphological characters be taken into account. He is of the opinion that in this way the important and transmissible characters of a plant may be most easily found, and that it gives to the newly bred varieties characters which are not influenced by climatic and soil conditions. While this line of work can be satisfactorily conducted only in specially equipped institutions, the efforts of the practical farmer and seedsman are to be applied in maintaining the productivity and the purity of the new variety after it leaves the institution.

What benefit can the farmer derive from plant breeding, variety tests, and seed growing? C. FRUWIRTH (*Wie kann sich der Landwirt Pflanzen-*

züchtung, Sortenversuche und Saatgutbau zu Nutze machen? Berlin: P. Parey, 1906, pp. 65, figs. 4).—The topics discussed in this book are plant breeding and the application of its results, the testing of varieties and breeds, seed growing, changes in a variety when taken to another locality, and the maintenance of the standard of a variety in general farm practice.

On the adulterants and weed seeds in Kentucky samples of blue grass, orchard grass, timothy, red clover, and alfalfa seeds, H. GARMAN (*Kentucky Sta. Bul. 124*, pp. 35, pls. 24).—Brief notes are given on the adulterants of Kentucky blue grass, orchard grass, red clover, Mammoth clover, and alfalfa, as well as on weeds of which seeds were found in seed samples examined under the Kentucky law. The sections of the law referring to Canada thistles are reproduced.

HORTICULTURE.

Cyclopedia of American horticulture, L. H. BAILEY and W. MILLER (*New York: Doubleday, Page & Co., 1906, vols. 6, 4, ed., ent., pp. XLIII+92+2016, pls. 145, figs. 2800*).—This work has been corrected in minor details, enlarged and increased in usefulness by the addition of a synopsis of the vegetable kingdom, with index of families and genera, making in all 92 pages of original matter. In the preface a rather extensive review is given of current horticultural progress. A large number of additional plates have been incorporated in the work.

Report of the South Haven Substation for 1905, T. A. FARRAND (*Michigan Sta. Spec. Bul. 35, pp. 30*).—This bulletin is the regular annual report on the orchard and small fruits and nuts grown at the South Haven Substation, and is similar in character to the previous ones (E. S. R., 17, p. 37).

A number of early and late varieties of potatoes were tested, as well as remedies for the San José scale. The most effective remedy for San José scale was the lime and sulphur mixture either with or without salt, in the proportion of 25 pounds of lime and 15 pounds of sulphur, boiled 35 minutes. This remedy cost but one cent per gallon, while a number of commercial preparations tried cost \$1.25 per gallon. The lime, salt, and sulphur mixture, as well as a number of commercial mixtures were also tried half strength on trees when in full leaf. All were more or less injurious. A commercial mixture, Scalecide, diluted to 1 to 20, was least injurious to the foliage, but even this did some injury. Sulphate of iron was used as a fungicide but proved without value as a spray on fruit trees.

Among the strawberries tested Bederwood and Gersonda stood out conspicuous, producing more fruit than any of the other varieties in either the old or new plantations. Notes are given on the varieties of currants, gooseberries, raspberries, blackberries, grapes, cherries, peaches, plums, apples, quinces, and chestnuts grown at the South Haven Station, with the results of spraying experiments in some instances and of a test of cover crops. The russetting of apples caused by spraying with Bordeaux mixture is believed to be due to the copper in the mixture, which in some way becomes soluble, since trees sprayed with sulphate of iron, Paris green and lime did not show the russetting, while it was quite apparent where sulphate of copper, Paris green, and lime were used.

Report of the horticulturist, G. F. WARREN (*New Jersey Stas. Rpt. 1905, pp. 281-292, pl. 1*).—The author made a study of the peach orchards of the State, giving some attention also to apples and asparagus. Popular notes are given on the enemies of these crops, especially insect pests and fungus diseases, with suggestions for their control. With attention to spraying, the peach industry can again be put upon a paying basis.

Report of assistant in horticulture, JENNIE A. VOORHEES (*New Jersey Stas. Rpt. 1905, pp. 295-332, pl. 1*).—A further report is given on the fertilizer, irrigation, and variety tests of vegetables and small fruits started at the station some years ago and regularly reported upon since then (E. S. R., 17, p. 363). The yields secured with asparagus, raspberries, blackberries, gooseberries, currants, pears, plums, cherries, apples, and peaches under the different and combined methods of treatment are shown in detail in tabular form and discussed. The results are not markedly different from those reported last year.

Report of the botanist, B. D. HALSTED, E. J. OWEN, and J. K. SHAW (*New Jersey Stas. Rpt. 1905, pp. 423-509, 517-525, pls. 17, dgm. 1*).—The work of the year has been along the plant breeding lines outlined in former station reports (E. S. R., 17, p. 364). In addition to the work with many sweet-corn crosses, a study was made of 36 varieties of popcorns, 35 crosses of summer and several winter squashes, crosses of many varieties of eggplants, green and wax bush beans, tomatoes, and salsify. The details of the work and the results obtained with each of these crops are given at length.

In crossing tomatoes the hybrids obtained seem to follow closely the laws of inheritance as outlined by Mendel, standard size, fine leaves, yellow foliage, red fruit and smooth fruit being dominant characters as compared with dwarf size, coarse leaves, green foliage, yellow fruit and hairy fruit, respectively.

Hybrids of the scarlet runner bean (*Phaseolus multiflorus*) and bush bean (*P. vulgaris*) were profuse bloomers and produced pods and beans much like the Scarlet runner parent. No results have been secured in crossing Limas and bush beans. A fertile hybrid was secured between the scarlet Chinese eggplant (*Solanum integrifolium*) and the Fordhook Improved variety (*S. melongena*).

After nine years' observation the weed experiment at the station has been brought to a close, the perennial species finally gaining the upper hand.

Notes on breeding and selection experiments with morning glories, primroses, marshmallow, Rose of Sharon, daisies, etc., are given, as well as methods of removing and preserving seeds, keeping records, marking stakes, and making ink prints of vegetable fruits.

Report of the horticulturist, F. GARCIA (*New Mexico Sta. Rpt. 1904, pp. 32-35*).—An outline of the work of the year, with some data relative to a test of varieties of potatoes and the yield of onions secured at the station. Of the 4 varieties of early potatoes tested Early Six Weeks gave the best results, the yield being \$6.67 bu. per acre. Celery was found to be pithy on the drier portions of the field, but where plenty of moisture was available this defect was not observed.

Importance of accurate descriptions, W. W. TRACY (*Amer. Florist, 26 (1906), No. 945, pp. 1128-1130*).—The desirability of accurate descriptions of varieties of vegetables in order that seed growers may produce plants true to type is pointed out. It is believed that if seed could be selected from plants of exact type for five generations, the improvement in seeds and market conditions would be greater than has come from the development of new varieties by hybridization or selection for the past 25 years.

Acetylene light for forcing plants, M. J. IORNS (*Cornell Countryman, 3 (1906), No. 8, pp. 183-185, figs. 2*).—The author first demonstrated the absence of any injurious qualities in acetylene light. Further, it was found that plants may be grown successfully in acetylene light without any sunlight whatever, though the plants are not quite as green as when grown in sunlight. In using it as a forcing agent it was found that as a general thing the warmer the house and the more sunshine the plants received the less visible was the effect of the acetylene light on the plants.

Sweet peas under the influence of acetylene light blossomed 5 weeks earlier than those not receiving the light. Easter lilies also responded promptly to the effects of the light. On the other hand, tomatoes, pole beans, and leeks showed little, if any, response to the light. The results secured with root crops were inconclusive.

It is concluded that with some special crops acetylene light will prove of undoubted commercial value. It is the nearest to being a complete substitute for sunlight that the author has found.

Forcing plants by means of ether, J. E. HOWITT (*Cornell Countryman*, 3 (1906), No. 8, pp. 187, 188, figs. 2).—Persian lilacs, subjected to fumes of ether November 24, were in full bloom December 25, 6 days earlier than those not etherized. When the plants were etherized 48 instead of 24 hours they bloomed 8 days earlier, and when etherized 72 hours 10 days earlier than unetherized plants.

When *Astilbe japonica* was etherized 24 hours it was in full bloom a month to 5 weeks ahead of another clump not etherized.

The book of rarer vegetables, G. WYTHES and H. ROBERTS (*London and New York: John Lane Co., 1906, pp. 109, pls. 7, figs. 30*).—Brief directions for the culture and culinary uses of a large number of the more rare garden vegetables. Among the more unusual described may be mentioned chervil, chick-pea, chicory, coco, commonly known as *Colocasia esculenta*, evening primrose, good King Henry (*Chenopodium bouus*), hops, nettles, oxalis crenata, patience (*Rumex patientia*), black Congo potatoes, fir apple potatoes, quinoa (*Chenopodium quinoa*), rampion (*Campanula rapunculus*), romaine (*Allium scorodoprassum*), scurvy grass (*Cochlearia officinalis*), skirret (*Sium sisarum*), sorrel, soy beans, sweet cicely, tuberous glycine (*Apios tuberosa*), etc.

Development of the Rockyford cantaloupe industry, P. K. BLINN (*Colorado Sta. Bul. 108, pp. 17*).—A historical account is given of the development of the cantaloupe industry at Rockyford from the first plantings to the present time. During the past 9 years 5,999 acres of cantaloupes have been shipped out of the Rockyford district. The yearly average is 666 acres. The largest number was shipped in 1904—1,182 cars. The cars used at present are 40 ft. long and carry 366 standard crates of 66 lbs. each. The Market Development of the Rockyford Cantaloupe is treated by H. Woods, and the Early Market Conditions of Cantaloupes on the New York Market, by Lyon Bros. Co. A brief paper on The Cantaloupe From a Luxury to a Necessity, by M. O. Coggins, is also included.

Onion growing, R. W. FISHER (*Montana Sta. Bul. 60, pp. 119-130*).—This bulletin contains the results of experiments in growing onions for three years, both from seed sown in the open and sown in greenhouses and transplanted. The period between killing frosts in Montana is placed at 100 to 120 days, while the time required for onions to mature from seeding is 135 to 150 days, and if onions are not thoroughly ripe their keeping quality is injured. The experiments are recorded in detail for each year and yields given by both methods of culture.

Generally speaking, the yields from transplanted onions were from 50 to 200 per cent larger than from seed sown in the field, while there was but little or no increase in cost of labor. The transplanting insures an even crop, the maturity of the crop, and the keeping quality of the onions. Prize Taker gave the largest average yield of the 19 varieties grown, and was one of the best keepers, though not usually advertised as a winter onion. The seedling bulbs of this variety, however, kept poorly because the growing season was not long enough to properly mature them. The use of well-rotted manure increased the

yield of both field-sown and transplanted onions. Suggestions are included for making hotbeds.

Notes on the truffle, E. BOULANGER (*Lous-le-Sannier; Lucien Declume, 1906, pp. 16, pls. 4*).—This pamphlet is made up of three papers presented before the Société Mycologique during the years 1904 to 1906 supplementing the author's work previously noted (E. S. R., 15, p. 472). In these articles various phases of truffle culture and spore germination are considered.

The best fruits for all sections, S. W. FLETCHER ET AL. (*Country Life Amer., 9 (1906), Nos. 5, pp. 571-574, 598; 6, pp. 760, 762, 764; 10 (1906), No. 1, pp. 100-106*).—A general discussion on the selection of fruits of high quality and planting, with recommendations as to varieties of orchard, bush, and other small fruits for each of the different States and Canada, the varieties suggested being largely those recommended by the horticulturists of the experiment stations.

Effects of stocks upon varieties, A. G. GULLEY (*West. N. Y. Hort. Soc. Proc., 51 (1906), pp. 14-20*).—Sweet Bough and Jersey Black varieties of apples were used as stocks upon which Red Canada and Red Astrachan were worked. No effect of the stocks upon the quality of the fruit could be detected. The use of Northern Spy as a stock did not delay the fruiting period of Jonathan or Red Canada worked upon it, showing again no visible influence of the stock on the scions.

Influence of bagging on the quality of fruit, M. GARNIER (*Rev. Hort. [Paris], 78 (1906), No. 9, p. 208*).—An account is given of some experiments carried on by Messrs. Rivière and Bailhache at the agronomic experiment station at Versailles on the composition of fruits as affected by bagging. Grapes and pears were the fruits investigated. The analysis of the fruit thus produced showed that the bagged grapes contained 205 gm. of sugar per liter of juice, while in the fruit not bagged there were but 198.5 gm. The acid content of the fruit grown in the bags was 2.86 gm. per liter of juice, and in the open 3.08. In the case of the pears, likewise, the total sugar content of the pulp in the bagged fruit was greater than in the fruit grown in the open. The acid content of the pears grown in the bags averaged 2.30 gm. per 1,000 parts of fresh pulp, as compared with 1.75 gm. for fruit grown in the open.

Fertilizer experiments with grapes, E. ZACHAREWICZ (*Prog. Agr. et Vit., (Ed. l'Est), 27 (1906), Nos. 4, pp. 118-122; 6, pp. 171-174; 7, pp. 215-218*).—Numerous experiments were made with fertilizers on different soils. Analyses are given of the soils and details of the results secured. The general conclusions drawn from the experiments are to the effect that nitrate of soda associated with sulphate of potash and superphosphate of lime is a valuable fertilizer, increasing the yields, hastening the maturity, and raising the sugar content of the fruit. In order to obtain maximum results with this manure, the sulphate of potash and superphosphate of lime should be applied in the fall and worked into the soil, the nitrate of soda being added the following spring in March or April, and also worked in.

The Görz prune industry with special reference to sulphuring the fruit, A. DEVARDA (*Ztschr. Landw. Versuchs. Oesterr., 9 (1906), No. 4, pp. 485-639*).—An account of the prune industry in the vicinity of Görz with the result of studies of various factors in the process of manufacture with the idea of improving the product. Only well-ripened fruit should be used for drying. The dried product should not contain over 25 to 30 per cent of moisture. In sulphuring the fruit not over 5 to 6 pounds should be used per hundred pounds of fruit, the duration of the sulphuring to last 20 to 30 minutes. In rainy weather sulphuring every 4 to 5 days is necessary. The time for each sulphuring under such conditions should not exceed 15 minutes. When pleasant weather again returns

the sulphured fruit should be fully exposed to sunlight and fresh air. Prunes in storage a year lose practically all the sulphuric acid they contain. A chemical study was also made of the free and organic sulphur in prunes and of the effect on the sulphur content of different methods of preparation for table use.

Home preservation of fruits, HENRIETTA W. CALVIN (*Industrialist*, 32 (1906), No. 34, pp. 533-535).—As a result of some experiments along this line, it is calculated that a bushel of peaches will can 16 to 20 qt.; blackberries and raspberries 13 to 17 qt. per crate; tomatoes 13 qt. to the bushel; grapes 1 pt. of juice to each 2 lbs. of fruit; medium-sized pineapples, 1 to a pint jar. With grapes 1 qt. of juice and 1.5 lbs. of sugar produced 6 glasses of grape jelly.

Preventing the decay of ripe fruit, T. R. SIM (*Natal Agr. Jour. and Min. Rec.*, 9 (1906), No. 3, pp. 202, 203).—Strawberries and Cape gooseberries were dipped in a formalin solution to prevent rot. The results were practically a failure as the dipped berries did not keep in good condition any longer than the untreated fruit and were greatly injured in appearance.

Utilizing waste apples, G. T. POWELL (*Amer. Agr.*, 78 (1906), No. 2, p. 24, fig. 1).—The author gives a drawing and detailed description of his two-story evaporating plant, and describes its method of operation, methods of packing the product, and the grades put up and prices received. It is stated that Baldwins will produce 6.5 lbs. of dried fruit to the bushel, Greenings 6 lbs., King 5.5 lbs., Ben Davis 4.75 lbs., Gilliflower 4.5 lbs., Twenty Ounce 5 lbs., Belleflower 5.5 lbs., Seek-no-Further 4.5 lbs., and Roxbury Russet 9 lbs.

Small fruits in 1905, J. P. PILLSBURY (*Pennsylvania Sta. Bul.* 77, pp. 10).—Popular data are given on the results secured in testing 48 varieties of strawberries, 27 of raspberries, 20 of blackberries, 2 of dewberries, 12 of currants, and 10 of gooseberries, with notes on the more important varieties.

Varieties of raspberries and blackberries, with cultural directions, O. M. TAYLOR (*New York State Sta. Bul.* 278, pp. 111-151).—Notes are given on the varieties of raspberries and blackberries cultivated at the station during the past 8 years, with general cultural directions and descriptions of a number of varieties of each. Among the red raspberries Cuthbert is stated to be the most popular variety throughout the State. Cline is an early variety, but the fruit is small and the plant unproductive. King and Royal Church are inclined to crumble. Marlboro is rather dwarf but very productive. The fruit of the Turner variety is considered too small.

The author states that purple raspberries are superior for canning. Their value for this purpose is not fully appreciated. Both Columbian and Shaffer are desirable kinds. Haymaker is productive and a promising variety.

Black raspberries require frequent renewal because of injury from anthracnose. A new variety, Beyer, ripens its fruit on the current season's growth, but it has not as yet shown many desirable characters. The varieties Cumberland, Gregg, Mills, and Onondaga produce fruit of excellent size and quality. Among the more desirable early kinds are Eureka, Mohler, and Palmer.

Agawam and Ancient Britain are among the better blackberries, producing large crops of berries medium to above in size. Snyder is the most cosmopolitan of all the varieties, very hardy and productive. Many varieties of blackberries require winter protection.

In the notes on the various varieties of berries a discussion is given of their earliness and hardiness, and descriptive and historical data given.

Raspberries and blackberries, O. M. TAYLOR (*New York State Sta. Bul.* 278, popular ed., pp. 12).—A popular edition of the above.

Table of the principal kinds of teas and representative tea-growing districts of the world (*Tea and Coffee Trade Jour.*, 10 (1906), No. 4, pp. 196.

197).—An extensive table showing the various tea districts in the world and the kinds of teas produced in each.

The fermentation of tea, I, H. H. MANN (*Indian Tea Assoc. [Pamphlet], 1906, pp. 22*).—Three former reports have been issued by the author on this subject (E. S. R., 17, p. 254), in which it has been shown that the oxidizing enzyme developed during withering is the principal and probably the only active agent in bringing about the changes of color and flavor which take place during fermentation. In the present report the changes which take place in some of the constituents of the tea itself, more specifically the tannin, are considered.

The marketable value of tea is closely connected with the quantity of tannin which may be easily extracted from the tea by boiling water. Caffein, which is the principal stimulating material of tea, does not bear a close relationship to market value. In good teas it appears to be present in quantities varying from 3 to 5 per cent, and in the lowest grades it may go down to 2 or 3 per cent. Analyses are given of several samples of tea to show that the market value is closely related to the total soluble matter and tannin content. Tannin is the chief source of pungency in teas, and is caused in greatest measure by the unfermented tannin. The color of the liquor, on the other hand, is caused chiefly by the fermented tannin. The body of the liquor is measured principally by the total soluble matter, of which a large part is tannin, fermented and unfermented.

The tannin in the leaf appears to be combined with sugar. During fermentation the enzyme of the tea causes slight oxidation of the tannin, as a result of which the sugar is separated and the tannin undergoes a loss of water and the colorless tannin of the tea leaf is transformed into brown products.

In investigations on the withering of tea it was found that "(1) The soluble matter and the soluble tannin in the leaf increase during the withering process, so long as the leaf does not dry up. (2) This increase in the important constituents of the leaf continues right through the process, so long as no drying takes place. . . . (3) So soon as the drying of the leaf takes place, a large reduction in the amount of soluble matter and soluble tannin is noticed."

Data are given which show that during fermentation a considerable reduction in the amount of soluble matter and soluble tannin in the leaf takes place, and this is increased with heavy rolling. In the absence of fermentation organisms it was found that normal fermentation of the leaf is complete in about 5.5 hours at most, including the rolling, where the temperature is maintained at 80° F. In fact, very little change takes place after 4 hours have passed. At a temperature above 85° F, a darker brown oxidation product of tannin is produced which is completely insoluble in water, the formation of which rapidly reduces the pungency, color, and body of the liquor and therefore greatly injures the quality of the tea. Among the practical conclusions reached is, that in order to make the best tea the temperature of the fermenting room must be kept down to 82° F. Suggestions are given on the construction of fermenting houses whereby this temperature may be maintained. This temperature, with a saturated atmosphere, and the absence of injurious organisms are believed necessary conditions to the manufacture of the best tea.

Some observations were made to determine the effect of light on fermentation, as some planters use yellow, some red, and some blue light in this process. The rapidity of fermentation was practically the same under white, red, and yellow light, but was less rapid under a blue light. No difference was noticed in the percentage of tannin, but only in the total soluble matter. The ultimate result was the same whatever the lighting used, providing direct sunlight and

glare were avoided. It is believed that where extremely short fermentations are given the blue light may have some advantage in producing better colored tea.

Investigations on the effect of thickness of spreading on the fermenting floor indicate that if the thickness did not go beyond 1.5 in. there was no noticeable difference in the results. Investigations in firing indicate that until the leaf is crisp or until no juice remains unsolidified, drying should be as rapid as possible, and at as low a temperature as possible, providing it is high enough to stop the normal fermentation of the leaf at once.

Relative to the absorption of moisture by made teas, it is found that teas when packed contain normally 2 to 3 per cent of moisture, when exposed for 15 hours the sample examined contained 9.6 per cent of moisture, after standing 26 hours, 10.4, and after standing 136 hours, 16.4 per cent. No marked change in the composition of the tea occurred, but when the tea was allowed to absorb moisture at a temperature of 90 to 100° F. for 17 hours there was a loss of both soluble matter and soluble tannin.

The renovation of deteriorated tea, H. H. MANN (*Agr. Jour. India, 1 (1906), No. 2, pp. 83-96*).—The author discusses the deterioration in tea plantations due to unfavorable physical conditions of the soil, exhaustion of plant food, bad pruning, etc., and suggests methods of correction.

Packing cocoa seeds (*Mo. Consular and Trade Rpts. [U. S.], 1906, No. 306, p. 115*).—It is reported that excellent results have been obtained in packing cocoa seeds for export by selecting seeds from ripe pods, thoroughly washing them in water and then gently rubbing them with a rough towel in order to remove most of the pulp. The seeds are then cooled in a current of air for 24 hours and packed in a material composed of equal parts of vegetable mold and finely ground powdered charcoal moistened just enough to resemble earth taken out of a shady place. The seeds are shipped in a tin box 8 by 4 by 4 in. A layer of earth and charcoal about $\frac{3}{4}$ in. deep is placed in the bottom of the box and then a layer of seed, leaving a little space between each seed, followed by a layer of charcoal and earth and then of seed until the box is full.

A neglected nut, J. W. KERR (*Country Gent., 71 (1906), No. 2786, pp. 594, 595, figs. 2*).—Shellbark hickory nuts from exceptionally good trees were secured in Pennsylvania and planted by the author in Maryland. They were from 13 to 15 years in coming into bearing. Ten of the better varieties thus obtained are briefly described and illustrations given of the nuts.

The seasons in a flower garden, LOUISE SHELTON (*New York: Charles Scribner's Sons, 1906, pp. 117, pls. 4*).—A popular garden book giving specific directions for the planting of different kinds of flowers and the work to be done in the garden during each month of the year.

The amateur gardener's rose book, J. HOFFMANN (*London, New York, and Bombay: Longmans, Green & Co., 1905, pp. XVI+155, pls. 20, figs. 16*).—This book has been translated into English by John Weathers and is intended primarily as an adviser to garden lovers who devote special attention to roses. It treats principally of the varieties grown in Germany and England. A feature of the work is 20 colored plates of as many different varieties of roses.

Handbook on pruning roses (*Croydon, Eng.: National Rose Society, 1906, pp. 83, figs. 14*).—Directions are given for pruning the different kinds of roses grown in England. Numerous illustrations are given to supplement the written descriptions.

A manual on the phlox, C. S. HARRISON (*York, Nebr.: 1906, pp. 31, figs. 6*).—This manual treats of the character and culture of different varieties of phlox, and is intended for the use of the nurseryman and amateur. Suggestions are also given on the showing of phlox and on the origination of new varieties.

The preservation of cut flowers, L. FOURTON and V. DUCOMET (*Rev. Hort. [Paris]*, 78 (1906), No. 11, pp. 260-262).—The results are given of experiments in preserving cut flowers by adding to the water in which they are kept various mineral and organic acids, bases, salts, antiseptics, etc. The flowers used were violets (*Viola odorata*), *Ficaria ranunculoides*, *Narcissus poeticus*, iris (*Iris germanica*), stellaire (*Stellaria holostea*), *Fumaria borci*, *Myosotis alpestris*, asperula (*Asperula odorata*), marguerite, seringal (*Philadelphus coronarius*), *Silene pendula*, snapdragon (*Antirrhinum majus*), and primrose.

The various materials were used in concentrations varying from 5 to 1,000 gm. per hectoliter. The test showed that it was advisable to use mineral materials in solutions less concentrated than 100 gm. per hectoliter. A mixture of mineral and organic materials did not give as good results as either alone. The length of time which each of the different flowers mentioned above could be kept by the various chemicals used is given in detail.

The following materials have proved useful in prolonging the life of cut flowers: Chloral, sugar, limewater, potash, etherized water, nitrate of potash, kainit, sulphate of potash, phosphate of potash, phosphate of ammonia, chlorid of calcium, glycerin, and alcohol. Mineral substances have been favorable in very weak concentrations—1 to 10,000—and organic materials have given favorable results in concentrations of 1 to 10 per cent. One of the conditions which has influenced the keeping quality of the flowers has been the distance of the surface of the liquid from the base of the flower. The keeping quality was longest when this distance was least. Flowers keep as well when cut as when left on the plant, providing water is supplied to the cut stems and putrid fermentation is prevented. The work is to be continued.

The effect of different chemical substances on the flowers of plants, J. C. HOGENSON (*Cornell Countryman*, 3 (1906), No. 8, pp. 188-190, fig. 1).—The effect of iron filings, copper sulphate, sugar, lime, salt, potassium hydroxid, iron sulphate, alum, and many other substances on the color of flowers, when added to the soil in which they were grown, was studied. So far as the experiment has gone it shows that with quickly-growing plants like narcissus and lily-of-the-valley no effect is noticeable. Azaleas and rhododendrons, which normally grow on acid soils, were successfully grown on limestone soils when these soils were made acid. This was conveniently done by adding magnesium sulphate, "which upon coming in contact with moisture of the soil hydrolyzes and forms magnesium hydroxid and sulphuric acid. The magnesium is absorbed by the soil and plant, thus setting the sulphuric acid free. This tends to neutralize the lime by acidifying the soil. Pyrogallol, tannic acid, and hydrochloric acid will also neutralize lime, but care must be taken not to put in too much. The results of this experiment are quite satisfactory."

Forcing bulbs by means of ether, C. I. LEWIS (*Cornell Countryman*, 3 (1906), No. 8, pp. 190, 191, fig. 1).—A large number of varieties of bulbs, such as narcissus, tulips, hyacinths, alliums, callas, gladiolus, lilies, etc., as well as seeds, were subjected to fumes of ether, using an ounce of sulphuric acid for every 14 gal. of space for a period of from 24 to 72 hours. Smaller amounts of ether were also used. With narcissus the gain in time of blooming from etherization was from 2 days to 3 weeks. With *Lilium longiflorum* var. *multiflorum*, there was no gain in early bloom, but a decidedly taller growth. With a longer exposure there was a considerable gain in time of blooming as well as in height.

Etherized seeds, such as peas, beans, radish, melon, lettuce, and onion, germinated sooner and more uniformly than unetherized seeds.

Wild flowers worth cultivating, W. MILLER (*Country Life Amer.*, 10 (1906), No. 3, pp. 322-327, figs. 15).—Six types of wild gardens, including bog

gardens, water gardens, rock gardens, etc., are described and the kinds of wild flowers used in planting them noted. Tables are given showing the common name, season of bloom, color, etc., of a large number of annuals and perennials which may be used in making wild-flower gardens.

FORESTRY.

Exotic forest and park trees for Europe, H. MAYR (*Fremdländische Wald- und Parkbäume für Europa*. Berlin: Paul Parey, 1906, pp. VIII + 622, pls. 20, figs. 258).—The trees described in this work are those grown primarily in North America, northern Mexico, Japan, Korea, Siberia, and northern China. Forestry conditions in these countries are described, based upon the author's personal observations, and the forest zones in the different countries outlined and compared with those of Europe. The cultural requirements and the uses of the various exotic trees dealt with are given with an account of their botany and correct nomenclature. General rules for the culture of exotic trees in Europe are given with plans for their culture in parks and forests.

Principles involved in determining forest types, R. ZON (*Proc. Soc. Amer. Foresters*, 1 (1906), No. 3, pp. 179-189).—This is a general paper on the subject in which it is held that a study of the life habits of forest trees and the establishment of forest types must go hand in hand. Yield and volume tables should be made separate for each type. If silviculture is to be placed on a safe basis each forest should be divided into permanent, natural forest types, or types of situation with forest growth corresponding to them in a manner similar to that of mapping soil types. It is held that when the laws of development and growth have been established for a forest type it will hold good for the same forest type everywhere, thus giving to silvicultural deductions the character of scientific truths of a wide application.

The rôle of light in forests, A. GIESLER (*Centbl. Gasam. Forstw.*, 32 (1906), Nos. 2, pp. 49-73; 3, pp. 97-122, *dgms.* 4).—Results and many of the details are given of extensive investigations to determine the effect of light on the crown and stem development of forest trees thinned to different degrees, and the corresponding floral development of the forest floor.

It appears that the crowns even of strongly lighted forests hold back a large portion of the chemical light rays. In the case of Austrian black pine this was found to be 60 per cent, fir forest 80 per cent, and red beech 90 per cent. The numerous small trees of lightly thinned forests do not retain proportionally as many of the chemical light rays as less numerous but more thickly leaved crowns of the larger trees found in more heavily thinned forests. Moderately thinned and heavily thinned forest trees contain practically two and four times as extensive a leaf area respectively as thinly forested trees.

A limit was found in the case of red beech, over which the mass production was no longer proportional with the increase in crown growth. Photometric studies with this tree favor thinning in the dominant condition, but not in the dominated.

When only 40 per cent of the chemical light rays reach the soil, the flora develops to such an extent as to hinder natural regeneration. In thickly closed stands of light-demanding trees the abundance, vigor, and number of species of plants on the forest floor were incomparably smaller than in a stand of tolerant trees, a fact of importance in the natural regeneration of such woods. Perennials made up 80 to 96 per cent of the flora species of forest floors.

Practical suggestions for the Massachusetts tree planter, R. C. HAWLEY

(*Mass. Forester's Off. Bul. 4, pp. 23, fig. 1*).—Suggestions are given for the preparation and care of a forest nursery, treatment in the nursery of the more important trees, planting out seedlings, with a discussion of the best species to plant, protection from fire, the cost of forest planting, and the returns to be expected from plantations.

The forestry problem in Canada, E. STEWART (*Ann. Rpt. Ontario Agr. and Expt. Union, 27 (1905), pp. 46-59*).—The author estimates the total amount of timber fit for lumber and pulp wood now growing in Canada at 532,000,000,000 ft. and the forest area at about 266,000,000 acres. In addition to this amount of timber there is an immense quantity that has not yet attained sufficient size for cutting.

Forestry in the East Africa Protectorate, E. BATTISCOMBE (*Indian Forester, 32 (1906), No. 3, pp. 115-120, pls. 2*).—The present activities of the conservator of forests in the East Africa Protectorate are to stop the encroachments of the natives in the destruction of the forests; to properly define the boundaries of the forests, and to find out the amount of timber available for extraction. A description of the forests at different altitudes from 5,000 ft. up is given.

Between the altitudes of 5,000 and 6,000 ft. the forests are composed essentially of hard wood of no great size. From this distance to 7,500 ft. the forests are varied, consisting of hardwoods and many quick-growing, large-leaved species. Juniper (*J. procera*) begins to appear at an elevation of 5,500 ft. and gradually increases in quantity with the elevation. This is the most useful forest tree in the country. Podocarpus begins at an elevation of about 7,000 ft.

Both these conifers flourish at an altitude of 8,000 to 8,500 ft., the former being found pure on the dry wind-swept hillsides, the latter preferring the deep soil of the broad-leaved forests but never found pure.

Bamboos appear at an elevation of 8,000 ft., while the tree limit is reached at about 8,500 ft. Rubber, derived chiefly from the species *Landolphia*, is found over nearly the whole of the Protectorate. A description is given of a small block of forest for which a working plan has recently been made.

Notes on the commercial timbers of New South Wales, J. H. MAIDEN (*Sydney: Govt. Printer, 1904, 2. cd., pp. 42, pls. 9*).—Popular information is contained in this pamphlet relative to the principal commercial timbers of New South Wales. The timbers of New South Wales are classified, their characteristics and principal uses pointed out, as well as their distribution, and the quantity available. The timbers are classified also as to special purposes for which they may be used.

Chaparral as a watershed cover in southern California, L. C. MILLER (*Proc. Soc. Amer. Foresters, 1 (1906), No. 3, pp. 147-157*).—A partial list of the species of trees forming the chaparral in southern California is given, with notes on the density of the chaparral in the Pasadena and Santa Ana watersheds at different elevations. The density of the chaparral appears to increase with the height from 2,000 to 3,000 ft. on east, south, and west exposures, and decreases in passing from the lower to the higher zones on northern exposures. In the improvement of California watersheds, it is stated that the question of fire protection must be solved before successful reforestation can be carried out.

Transverse test of *Catalpa speciosa* (*Arboriculture, 5 (1906), No. 4, p. 109*).—The results are given of two bending tests of this species of catalpa, using posts 3.5 in. in diameter and 8 years old. The average load carried when the distance between each post was 4 ft. was 795 lbs., and when the distance was 2 ft., 1,243 lbs.

How spurious seed is disseminated (*Arboriculture, 5 (1906), No. 4, pp. 113, 114*).—The results of an examination of 21 samples of catalpa seed from 19

firms are given. In every case the catalpa seed was bought for *Catalpa speciosa*. Nine of the samples were found to be *Speciosa bignonioides*, while a number of others were hybrids. Only 3 of the samples were pure *Catalpa speciosa* seed.

Grafting chestnuts on oak for the reconstruction of chestnut orchards, BIXON (*Bul. Soc. Nat. Agr. France*, 66 (1906), No. 4, pp. 345-348).—Of the oaks with which the author worked *Quercus pedunculata* seemed to be the only one which he could recommend as a stock for chestnuts. Tests with the American red oak did not give satisfactory results. Grafting by the flute or whip method is recommended, the operation being performed when vegetation commences in the stock.

On the increment and form of growth of larch trees, G. SCHOTTE (*Skogs-rårdsför. Tidskr.*, 4 (1906), No. 1, pp. 18-23, figs. 3).—Siberian larch grown in Sweden was found to have an average height, when 2 years old, of 18.7 cm. (range 9-28 cm.), and European larch, 12.1 cm. (range 5-19 cm.). The former were of straight growth without many branches, while the latter ramified strongly even the first or second year and acquired a shrublike habit of growth.—F. W. WOLL.

Litter experiments in large pine forests, K. BÖHMERLE (*Centbl. Gesam. Forstic.*, 32 (1906), No. 4, pp. 145-165, figs. 7).—The amount of litter produced and the increment growth on separate areas in forest are given for 5 year periods for the 20 years from 1882 to 1903. In one case the trees were 37 years old at the beginning of the experiment, and in the other 57 years old. In some instances the litter was removed annually and in others at the end of 5 years, and in still others not removed at all. When the litter was harvested yearly, about four cords or 3,000 pounds dry matter per acre was secured. When harvested at the end of five year periods, only 51 to 53 per cent of the average yearly leaf fall was secured, owing to the decay of the older matter. The removal of litter had but little effect on tree growth, probably due to the stimulation from annual raking and to the deleterious effects of moss growth which was greatest on the plats raked only every 5 years. The data are given in extensive tabular form largely as a report of progress.

On the drying up of pine forests in northern Sweden in the spring of 1903, G. ANDERSON (*Skogs-rårdsför. Tidskr.*, 3 (1905), No. 12, pp. 449-477, figs. 7, map 1).—The disease manifested itself in the drying up of more or less of the new tip growths, some districts being much more affected than others. The cause could not be determined with certainty, but is thought to be due to unfavorable weather conditions. A résumé in German is given and a map showing the affected districts.

Size of seed as related to vigor of germination and seedlings, G. EISENMENGER (*Österr. Forst u. Jagd Ztg.*, 24 (1906), No. 22, pp. 185, 186, figs. 6).—As the result of experiments with seed of spruce, Scotch and Austrian pine, the author found that large seeds germinated quicker and reached the period of maximum germination earlier than small seeds. The dark-colored seed of spruce and Austrian pine gave a larger percentage germination than light-colored seeds, while large dark-colored seed of both these trees produced much larger and more vigorous seedlings than large light-colored seeds. Small light-colored seeds produced the weakest seedlings of all.

Rubber culture in the Philippine Islands, W. I. HUTCHINSON (*Forestry and Irrig.*, 12 (1906), No. 5, pp. 230, 231).—An account is given of the planting of Para, Ceara, Castilloa, and Rambong seed during the year 1905, with some measurements of seedlings with reference to growth. Para rubber seedlings in 50 days averaged 15 in. in height. Ceara seedlings 7 months and 5 days

old averaged 12 ft. 5 in. in height. At a lower elevation the average height was 9 ft. 9 in. Castilloa seedlings about 5 months old averaged 17 in. in height.

History of a rubber creeper in tropical Africa (*Landolphia dawei*), M. A. CHEVALIER (*India Rubber Jour., n. ser., 31 (1906), No. 10, pp. 514-517*).—This article is a translation of the official report of the Botanical Society of France, and contains a botanical description of *Landolphia dawei*, *Clitandra elastica*, and *L. turbinata*. It is held that the *L. florida* of Dr. Preuss is identical with *L. dawei*. This creeper is believed to be the most promising rubber plant of a creeping nature now known with reference to tropical agriculture.

Coagulation of Castilloa rubber, S. W. SINCLAIR (*Bul. Dept. Agr. [Jamaica], 4 (1906), No. 5, pp. 99, 100*).—The author's method of coagulating Castilloa rubber consists essentially in the use of a box about 1.25 in. deep with a filter-paper bottom. When the latex is brought in from the field, about 4 times its volume of water is added. The mixture is then strained and allowed to settle in a cone bottom tank, after which the water is decanted off and the latex poured into the box. The surplus water rapidly passes through the filter paper and the remaining rubber layer is exposed to a heat of 110° F. for 5 to 6 hours. After being used 10 or 12 times the filter paper must be replaced. This method is suitable for Castilloa only. The Hevea latex passes through the filter paper.

Exportation and packing of Hevea seeds, U. BERNARD (*Jour. Agr. Trop., 6 (1906), No. 58, pp. 99-101*).—An account is given of sending hevea seeds from Penang in the Malay States to Holland, packed as follows: 1 and 2, charcoal saturated with benzine; 3, charcoal; 4, dried leaves; 5, sand, the seeds being first previously well dried; 6, sawdust; 7, sawdust saturated with benzine. None of the seed germinated which had been packed in material saturated with benzine. Seeds packed in charcoal alone gave 66 per cent germination; in sand and dried leaves, 46 per cent, and in sawdust, 25 per cent.

DISEASES OF PLANTS.

Report of the botanist, G. P. CLINTON (*Connecticut State Sta. Rpt. 1905, pt. 5, pp. 263-330, pls. 13, figs. 2*).—Notes are given on various fungus diseases observed during 1905 and accounts of investigations made upon the downy mildew (*Phytophthora phascolii*) of Lima beans and the downy mildew or blight (*P. infestans*) of potatoes.

During the season of 1905 fungus diseases on the whole were less troublesome in Connecticut than for several years previous, and the author calls attention to a number which have not hitherto been reported as occurring within the State. Among these were a fruit speck of apples due to an undetermined species of fungus, and a pod and leaf blight of Lima beans, which resembled that described as due to *Phoma subcircinata*, although the author states that his specimens did not agree with the description of that fungus and that the fungus might be a species of Ascochyta, possibly *A. phascolorum*. Among the other diseases described are leaf scorch of the sugar maple, which is due to some physiological disturbance, probably drought or winter injury to the roots; wilt of okra, and a disease of onions to which the name brittle is given and which is believed to be caused by a species of Fusarium. This disease is generally characterized by the brittleness of the onion leaves, and from this character its name is taken. An examination of the above-ground parts failed to reveal the presence of any insect or fungus attack, but when the underground portions were examined the smaller roots were found to possess irregular swellings, and when examined microscopically the mycelium of some fungus was found present. Specimens exposed in moist chambers for several days developed a fungus that is believed

to be species of *Fusarium*. Experiments with soil taken from infested fields produced the disease, and as the trouble is apparently due to some soil fungus, a rotation of crops, the use of commercial fertilizers, etc., are recommended.

The author also reports the occurrence of *Botrytis patula* on raspberries, causing a gray mold, and associated with it was the cane wilt fungus (*Leptosphaeria coniothyrium*). The occurrence of *Heterosporium variable* on spinach leaves, producing the leaf mold, is mentioned, and while the fungus does not appear to be a very vigorous parasite, yet the spots caused by it on the leaves depreciate the market value of the spinach to a considerable extent. A brief account is also given of the damping off of tobacco plants, which was suspected as being due to a *Rhizoctonia*, but an examination of specimens did not reveal this fungus in any of the young plants. Cultures of diseased material were made, and while they never produced any spores the sclerotia formed resembled those attributed to *Sclerotinia*, and it was thought possible that the fungus in this case was a species of that genus.

In the studies on the Lima bean mildew the author reviews the previous investigations, describes the various stages of growth, and reports having found the oospores, thus completing the life cycle of the organism. Attention is called to the fact that, aside from notes on the limited distribution of the Lima bean mildew, practically all that is known about it has been worked out by the various botanists connected with the station. The microscopical characters of the fungus are described at considerable length, and the oospores, which the author was the first to discover, are found in the seed coats and cotyledons of the seeds and to a limited extent in the tissues of the pods, but not in the stems or leaves. Artificial cultures were successfully made, and both conidial and oogonial stages were formed. The presence of the oospores in the seed emphasizes the necessity for proper selection as a precaution against the disease, but in addition the rotation of crops, the destruction of rubbish, spraying, proper cultivation, etc., are recommended. A bibliography of literature relating to this fungus completes the account of this disease.

In continuation of the work of the author in 1904 (E. S. R., 17, p. 153), studies were carried on on the downy mildew or blight (*Phytophthora infestans*) of potatoes, the author seeking to determine the means by which the fungus first infects the vines in the summer, the means by which it is carried over from year to year, the inoculation of the tubers, etc. The author believes that one of the means of primary infection is through the contact of the leaves with the ground at critical wet periods during July and August, when the germs of the blight are probably first generally available in the soil for infection. While the author has not yet determined from his own observations whether the fungus is carried over the winter in the soil, so far as the observations go they seem to indicate that blight starts earlier and more vigorously in fields that bore a blight-diseased crop the year before, and such factors as earliness of planting, situation of land, previous crop, etc., must be considered. Notes are given on secondary infections, growth in artificial cultures, perpetuation of the fungus, etc., and in commenting on the delayed appearance of the blight, the author advances the opinion that its appearance in July and August is to be attributed possibly to the fact that the mycelium from primary infections on young, rapidly growing tissues remains localized until after vegetative growth of the host ceases and then renews its activity on the appearance of favorable weather conditions. If the primary infections take place, as the author believes, by contact of the leaves with the ground, this would best be accomplished after the plants have attained full growth.

Plant diseases of the year, W. PADDOCK (*Colorado Sta. Rpt. 1905, pp.*

44-46).—Brief accounts are given of diseases observed during the year. Among them are grape mildew, peach mildew, raspberry yellows, asparagus rust, bacterial blight to tomatoes, strawberry leaf blight, and *Rhizoctonia* of sugar beets.

Report of the horticulturist, F. M. ROLFS (*Florida Sta. Rpt. 1905, pp. 29-47*).—A report is given of observations made relating to the diseases of a large number of plants of economic importance, the diseases being listed under the different host plants. Directions are given for the preparation and use of a number of standard fungicides.

Fungi as related to weather, B. D. HALSTED, E. J. OWEN, and J. K. SHAW (*New Jersey Stat. Rpt. 1905, pp. 516-517*).—A tabular account is given showing the rainfall, temperature, and sunshine, and also statements regarding the occurrence of plant diseases during the months from April to September. The rainfall was somewhat below the average during the early part of the summer, but it exceeded the normal in August and September. Comparing the rainfall, dryness, temperature, etc., with the reported occurrence of diseases there seems to be shown a close relationship between the occurrence of diseases and the meteorological conditions. The occurrence of fungi on various economic plants in the station grounds is briefly noted.

Channels of entrance and types of movement in bacterial diseases of plants, E. F. SMITH (*Abs. in Science, n. ser., 23 (1906), No. 585, pp. 424, 425*).—A discussion is given of the various ways in which bacteria enter living plants, and some doubt is expressed as to whether certain stomatal infections may not take place through the action of drops of water standing on the plant, causing the destruction of cells underneath the epidermis. While this may account for infection through stomata, it does not remove the possibility of infection through the water pores. The various means by which the bacteria are distributed through the plants are briefly mentioned, and the author states that the transpiration stream appears to have little to do directly with the movement of bacteria in the stems of diseased plants. It appears that in some cases bacteria are able to pass from cell to cell through the pits or thin places in the cell wall without any extensive solvent action being necessary. Attention is also called to the distribution of starch in young potato tubers affected by *Bacterium solanacearum*. This organism has little diastatic action on potato starch, and the irregular distribution of the starch in affected tubers seems to indicate the paralysis or destruction of considerable areas of tissue surrounding the bacterial foci, so that it is impossible for the plant to store up the starch in such cells.

Cultures of Uredineæ in 1905, J. C. ARTHUR (*Jour. Mycol., 12 (1906), No. 81, pp. 11-27*).—An outline is given of culture experiments with some 30 species of rusts which have been successfully grown during 1905, particular attention being called to the plum rust (*Puccinia pruni-spinosa*). The author investigated the possible relationship between *Aecidium punctatum* occurring on various species of Anemone, Hepatica, etc., in the United States and the rust of plum, and as a result of his investigations he arrives at the conclusion that there is no doubt of the general identity of the American and European plum and cherry rusts and their connection with *Aecidium punctatum*.

Experiments with *Puccinia sorghi* in 1905, W. A. KELLERMAN (*Jour. Mycol., 12 (1906), No. 81, pp. 9-11*).—In a previous report (E. S. R., p. 787) the author gave a brief account of some experiments with the maize rust, and in the present publication a summary of previous work is included and the results of his experiments in 1905 are described.

Attention is called to the discovery of the aecidium stage on *Oxalis* by Dr. J. C. Arthur (E. S. R., p. 986), and the author states that by using teleutospores of the maize rust he has been able to secure the aecidium on *Oxalis*, thus com-

pleting the demonstration of the relationship between the two different forms of the fungus. The author believes it is very probable that a few viable uredospores are carried over the winter in the teliosporic pustules and in this case give rise to the infection of corn, and it is doubtless a fact that the rust is carried over from year to year in part by means of surviving uredospores.

The curly top or western blight of the sugar beet, C. O. TOWNSEND (*Abs. in Science, n. ser., 23 (1906), No. 585, pp. 426, 427*).—An abstract is given of a paper by the author in which there was a discussion of various theories that have been investigated as to the cause of the curly top or western blight of the sugar beet. These theories included the action of parasites, unfavorable soil, climatic, and cultural conditions, and inherent tendencies in the plant toward the disease. The bacterial theory has heretofore received more attention than others, but the results thus far seem to show that none of the organisms isolated from diseased beets is the sole cause of curly top. In some instances parasitic fungi have been found in the tissues, but inoculations made with the fungus in healthy plants in the field have not produced the disease under the conditions employed. It is believed that a combination of unfavorable conditions is necessary to produce the curly top, and the most important discovery thus far made in connection with the disease is that it does not usually attack beets in the same locality or even in the same field two years in succession.

Some diseases of beans, H. H. WHETZEL (*New York Cornell Sta. Bul. 239, pp. 197-214, figs. 16*).—This bulletin is largely compiled from previous publications of the New York State Station, the New Jersey Stations, and the Ontario Agricultural College (E. S. R., 4, p. 557; 13, p. 466; 16, p. 477). The diseases described are the anthracnose due to *Colletotrichum lindemuthianum*, bacterial blight caused by *Bacterium phaseoli*, and bean rust due to *Uromyces appendiculatus*. The nature of these diseases and methods of treatment are discussed, the author contributing a number of illustrations and notes on the life histories of the organisms.

Irish potato diseases, J. B. S. NORTON (*Maryland Sta. Bul. 108, pp. 63-72, figs. 4*).—This bulletin is based on observations by the author and also publications of the New York State Station, the Vermont Station, and this Department. The diseases described are scab, Rhizoctonia, dry rot, bacterial rot, and early and late blight, and suggestions are given for their prevention.

Spraying notes, 1904-5, E. R. BENNETT (*Connecticut Storrs Sta. Bul. 41, pp. 48-65, figs. 8*).—During the seasons 1903, 1904, and 1905, experiments were carried on with Bordeaux mixture for the prevention of late blight of potatoes, and the results obtained in the different years did not agree in all respects. In 1904 but little difference was noticed between the sprayed and unsprayed rows, but the results in 1903 and 1905 showed that on the whole spraying is very beneficial.

In 1905 the experiments were continued to ascertain the least number of applications of Bordeaux mixture that would be necessary to prevent loss from blight. With this in view, different plats were sprayed with fungicides and the check plat was sprayed with Paris green to protect it from insects. One plat was sprayed twice with Paris green, once with Paris green and Bordeaux mixture, and once with Bordeaux mixture; a second similar area was given 7 sprayings, the first and third having Paris green added to the mixture; and on still another plat 8 sprayings were given, the first 3 being of Bordeaux mixture and Paris green and the last 5 Bordeaux mixture alone. The total yields per acre from the different plats were as follows: Check plat 42.5 bu.; plat No. 2, which received 2 sprayings of Paris green and 2 of Bordeaux mixture, 180 bu.; plat 3, which received a total of 7 sprayings, 270 bu.; and plat 4, which received 8 sprayings, 345 bu. per acre.

Observations were made on the possibility of preventing discolored potatoes from rotting after digging, and it was found that where the discoloration was due to the presence of a fungus nothing could be done to stop the rot. There appears to be little indication that the disease spreads in the soil after ripening, and on this account it is recommended that potatoes rotting in the ground should be left as long as the season will permit before digging.

Notes are given on tomato spraying, in which Bordeaux mixture was applied on 9 different dates for the prevention of leaf spot, and while the treated vines remained green until frost, no data relative to the weights of fruits or yields were kept. In another series of experiments the plants were given 5 applications of Bordeaux mixture, and the yield of sprayed and unsprayed plants is shown in tabular form. In every case the yield from the sprayed plants was largely in excess of that from the unsprayed ones.

In a previous publication of the station (E. S. R., 16, p. 66) an account is given of spraying cucumbers for the prevention of blight. These experiments have been continued, and as the result of 3 years' work with Bordeaux mixture on cucurbits it is shown that there was a decided increase in yield for the first and third years, when the downy mildew was present, and a decided decrease the second year, when no fungus was troublesome on the plants. This showing raises the question as to whether it pays to spray melons and cucumbers, and in the absence of knowledge relative to the probable occurrence of disease, it would doubtless pay to spray the plants or at least to be prepared to give thorough spraying on the first appearance of disease.

Potato spraying experiments in 1905, F. C. STEWART, H. J. EUSTACE, and F. A. SIRRINE (*New York State Sta. Bul.* 279, pp. 153-229, pls. 5, map 1).—A report is given of the fourth year's experiments in potato spraying carried on by the authors in the 10-year series of experiments which have been previously described (E. S. R., 14, p. 875; 15, p. 781; 17, p. 46).

During 1905 the experiments carried on by the station at Geneva gave an increase of 119½ bu. per acre when the plants were given 5 sprayings and 107 bu. when given 3 sprayings. At Riverhead, on Long Island, the gain due to 5 sprayings was 82 bu. per acre and to 3 sprayings 31½ bu. At this place the flea beetle was the chief enemy of the potato.

In what are called the farmers' business experiments, in which potatoes were sprayed under the direction of the station officers, in 13 experiments, including 166⅓ acres, the average gain due to spraying was 46½ bu. per acre, the cost of spraying \$4.25 per acre, and the average net profit \$20.04 per acre. In 50 volunteer experiments, including 407 acres of potatoes, the gain due to spraying was 59½ bu. per acre, and the average net profit in 29 of the experiments was \$29.85 per acre.

In comparative tests of the efficiency of soda Bordeaux and lime Bordeaux mixture the rows sprayed 4 times with lime Bordeaux yielded at the rate of 9 bu. per acre in 1 test and 35 bu. per acre in another test more than similar plats sprayed with soda Bordeaux. The addition of Paris green or arsenate of soda to Bordeaux mixture can be performed without any danger of injury where used in moderate amounts.

During 1905 in unsprayed fields the loss from blight, rot, and flea beetles was estimated at 50 bu. per acre. The experiments conducted by farmers in the past 3 years have shown net profits due to spraying of \$22.79 per acre.

The authors recommend beginning spraying when the plants are 6 to 8 in. high and repeating it throughout the season at intervals of 10 to 14 days, or until 5 or 6 applications have been given the plants. When bugs are troublesome Paris green or other poison may be added.

Good results from spraying potatoes, F. H. HALL ET AL. (*New York State Sta. Bul.* 279, popular ed., pp. 16).—A popular edition of the above.

Spraying for potato blight in 1905, C. A. MCCUE (*Michigan Sta. Bul.* 236, pp. 131-143, figs. 2).—After briefly describing the cause of potato blight, the author gives the results of experiments in which potatoes were sprayed with Bordeaux mixture and comparisons made with similar plats receiving a spraying of lime water. Where the potatoes were given 14 sprayings of Bordeaux mixture at intervals of 4 days a net gain of \$11.90 per acre is reported. Where they were sprayed at intervals of 10 days, 6 applications being given, a net gain of \$15.44 per acre is given. On plats sprayed every 15 days a net gain of \$13.38 per acre is reported, and where given 4 sprayings at intervals of 20 days \$11.03 per acre net gain is reported. For the plat which received 14 sprayings of lime water at intervals of 4 days a loss of \$1.76 is reported. The cost of the spraying is said to have been 72 cts. per acre for each application. This amount the author believes could be reduced to not more than 55 cts. per acre.

The author gives compiled information relative to spraying by individual farmers, the results obtained at other stations, etc., and notes that the station expects to carry on experiments for the prevention of late blight for at least 5 years.

The spraying of potatoes for prevention of leaf blight and rot, E. P. SANDSTEN and J. G. MILWARD (*Wisconsin Sta. Bul.* 135, pp. 24, figs. 7).—In 1904 experiments were begun in spraying potatoes for the prevention of blight and rot and continued in 1905, the details of the experiments being described in the bulletin. In the different experiments in 1905 important gains were noted for nearly every treated lot, in some cases the gains ranging from \$19.20 per acre to \$36 per acre, which were made at a cost of less than \$4 per acre for spraying.

The control of apple bitter rot, W. M. SCOTT (*U. S. Dept. Agr., Bur. Plant Indus. Bul.* 93, pp. 36, pls. 8, fig. 1).—An account is given of experiments for the control of the bitter rot of apples, which is due to the fungus formerly known as *Gleosporium fructigenum*, but which has received the name *Glomerella rufo-maculans*. A detailed account of the disease and the fungus has been given in a previous publication (*E. S. R.*, 15, p. 270).

In the present bulletin the author briefly describes the fungus, and the relation of bitter-rot cankers on the branches of trees to infection, which was previously noted (*E. S. R.*, 14, pp. 367, 581; 15, p. 270), is discussed at some length. A discussion is given of the effect of moisture and temperature on the disease, and the relative susceptibility of different varieties is commented upon.

The investigations which are reported were carried on in Nelson County, Va., in a region famous for the production of Yellow Newtown or Albemarle Pippin apples. The object of the experiment was to determine to what extent bitter rot can be controlled by spraying with Bordeaux mixture, the number of applications required, and the proper time to make the applications. The season of 1905 was so favorable to the development of bitter rot and the disease appeared so early and continued with such abundance throughout the season that the results obtained are believed to be a safe guide for almost any season.

It was found that bitter rot can be almost completely controlled by proper applications of Bordeaux mixture, 93 to 98 per cent of sound fruit having been saved by such treatment, while the fruit of the trees not sprayed rotted completely. Four applications made at the proper time are believed to be sufficient to control the disease, and these should be made at intervals of 2 weeks, beginning about 6 weeks after the trees bloom. Thorough applications of Bordeaux mixture are necessary, so that the fruit may be well coated with the fungicide.

Other diseases, such as scab, leaf spot, and sooty blotch may be controlled in

connection with the treatment for the bitter rot. For the combined treatment of apple scab and bitter rot the trees should be sprayed just before they bloom, as soon as the petals fall, a week to 10 days later, and about 6 weeks after the shedding of the petals, to be followed at intervals of 2 weeks thereafter until 7 or 8 applications have been given.

In a dry, cool season the intervals between the later sprayings may be lengthened. On the other hand, in a hot, humid season it will probably be found necessary to shorten the intervals and increase the number of applications. If the treatment for any reason should be delayed until after it is discovered that infection has taken place, the trees should be thoroughly sprayed twice in rapid succession with an interval of a few days in order to coat the fruit thoroughly as quickly as possible.

The wrapping of apple grafts and its relation to the crown-gall disease, H. VON SCHRENK and G. G. HEDGCOCK (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 100, pt. 2, pp. 12*).—In a previous publication (*E. S. R.*, 17, p. 779) the nature and cause of crown-gall disease of apple trees and its different types are discussed, and in the present publication only 2 forms are considered, the hairy root and the crown gall. The hard and soft types of the crown gall have not yet been fully differentiated.

In the present paper an account is given of experiments in which cloth, rubber, waxed paper, plain thread, waxed thread, and plain thread with union waxed were tested to determine their effect in preventing the occurrence of crown gall by providing conditions under which a perfect union is formed between the stock and scion in the shortest possible time. A large number of grafts were made, and the detailed results are shown, from which it appears that wrapping the grafts reduced the number of crown-gall trees very materially.

The most effective wrapping, so far as the true crown gall is concerned, was that made of rubber, followed closely by cloth. The cloth wrappings, however, showed the highest percentage of smooth trees, when not only the crown gall but also the hairy root form were considered. From the results thus far obtained, the use of either cloth or rubber as a material for wrapping apple grafts is recommended, and when the question of expense is to be considered it is believed that cloth will be found more desirable, as in most cases it gives results fully as satisfactory as rubber. The writers strongly advise against the wrapping of grafts with thread and subsequently waxing the grafts.

Peach mildew, O. B. WHIPPLE (*Colorado Sta. Bul. 107, pp. 7, figs. 2*).—According to the author, peach mildew has made its appearance in some parts of Colorado, and the purpose of the bulletin is to point out the nature of the disease and describe some of the means of combating it.

Notes on rougeot of grapes, L. RAVAZ and L. ROOS (*Compt. Rend. Acad. Sci. [Paris], 141 (1905), No. 6, pp. 366, 367*).—The authors claim that this disease is characterized by an accumulation of red coloring matter in the leaves and is produced under varying circumstances. They reject the theory that it is caused by the development of parasites within the leaves and show that it may be produced by the ringing of a branch or the severing of one of the principal veins of a leaf. That the disease is not parasitic they claim is further shown by analyses of many parts of the vines at different stages of growth. Their figures show that in the diseased vines there is a large accumulation of starch and sugar in the diseased parts and a deficiency of lime and magnesium in most parts of the affected plants.

Cranberry spraying experiments in 1905, C. L. SHEAR (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 100, pt. 1, pp. 8 fig. 1*).—In a previous publication (*E. S. R.*, 17, p. 51) a brief account was given of cranberry diseases and the results of

spraying experiments with Bordeaux mixture. The results in 1904 were not entirely satisfactory and the experiments were repeated in 1905 with greater success. Applications were made of Bordeaux mixture to which was added $4\frac{1}{2}$ lbs. of commercial resin-fishoil soap to 50 gals. of the solution. Different plats were sprayed at different dates during the season, and in addition to the experimental plats several acres were treated, and the results showed marked differences in the appearance of the fruit on the sprayed and unsprayed plats by the middle of summer.

In order to determine whether any injury would result from spraying plants while in bloom, one plat was sprayed while in full bloom and the fruit compared with that on adjoining plats not sprayed. No difference could be noticed in the amount of fruit on the sprayed and unsprayed plats.

In order to compare the keeping qualities of sprayed and unsprayed fruit, more than 3,000 berries were collected and placed in glass dishes in the laboratory and counted each week to determine the amount of disease which developed. On October 18, about the time the fruit from the bog was marketed, 9.8 per cent of the sprayed fruit showed diseased berries, while 38.1 per cent of the unsprayed fruit and 37.4 per cent of fruit which had been treated with a simple copper sulphate solution were decayed. In other words, four times as much of the unsprayed fruit decayed between the time of picking and marketing as of the sprayed fruit.

As a result of 3 years' spraying experiments, it is believed that by the proper use of Bordeaux mixture the loss from fungus diseases may be reduced to 10 per cent or less. As a rule the benefit is more marked in the second year than the first, and this is evident not only in the prevention of scald and rot of the fruit, but in the general improvement and productiveness of the vines.

The cost of spraying in the experiments described above averaged from \$15 to \$20 per acre, about 1,000 gals. of solution being applied in 5 applications.

A new disease of coffee in New Caledonia, I. GALLAUD (*Compt. Rend. Acad. Sci. [Paris]*, 141 (1905), No. 22, pp. 898-900).—The author reports the occurrence on the coffee trees of New Caledonia of the fungus *Pellicularia kolcroga*. This parasite which was first described from Mysore in 1880 has since been reported from Venezuela and now from New Caledonia. In Venezuela it is said to have proved a very serious pest, and attention is called to the disease to prevent its spread if possible.

The fungus makes its appearance during the rainy season at a time when the coffee trees are most actively growing, and attacking the leaves it causes them to turn yellow, and finally the entire tree is defoliated and killed. In addition to the leaves it is found on all the aerial organs of the plant, causing by its brownish mycelium the presence of yellowish-brown patches on the leaves, fruits, etc.

The fungus seems to be a superficial one, and it is thought that probably it can be held in check by the use of fungicides without injury to the host plant. Experiments along this line are to be undertaken.

Cacao diseases, II (*Bul. Dept. Agr. [Jamaica]*, 4 (1906), No. 1, pp. 11-13).—A description is given of a pod disease of cacao due to the fungus *Diplodia cacaoicola*, most of the information being drawn from another source (E. S. R., 13, p. 964).

A tree-strangling fungus (*Jour. Bd. Agr. [London]*, 12 (1906), No. 11, pp. 690-692, fig. 1).—A description is given of *Thelephora lacinala*, a fungus that, while not parasitic, is more or less destructive to seedlings through its growth about the base of the stems. The fungus adheres closely to the stem, giving it

a frilled appearance, and may extend up the stem for a distance of 6 in. to a foot or more. When badly attacked the plants frequently are destroyed.

Violet root rot (*Jour. Bd. Agr. [London], 12 (1906), No. 11, pp. 667, 668, pl. 1*).—The author briefly describes the disease due to *Rhizoctonia violacea*, a fungus which attacks alfalfa, clover, carrots, beets, mangels, and potatoes. On account of the wide range of host plants, care must be exercised in rotation experiments, and injury due to the fungus may be prevented to a considerable extent by proper rotations, drainage, culture, and seed selection.

Broom rape on pelargonium, B. D. HALSTED, E. J. OWEN, and J. K. SHAW (*New Jersey Stas. Rpt. 1905, p. 509, pl. 1*).—An account is given of the attack by one of the broom rapes (*Orobancha minor*) on pelargoniums growing in the greenhouse at the station. The author also notes the occurrence of *O. ramosa* on tomato plants under the same conditions.

Spraying mixtures, W. E. BEAR (*Jour. Bd. Agr. [London], 12 (1906), No. 11, pp. 660-666*).—The author calls attention to the unsuitability of some fungicides for general use, and states that the spraying of fruit trees and bushes is at present in an empirical stage. He suggests that experiments should be carried on to put the practice on a more satisfactory basis. These would include investigations on the effective strength of solutions, importance of purity of materials, and the proper times for spraying.

A method for the determination of the fineness of sulphur used as a fungicide, C. DUSSERRE (*Ann. Agr. Suisse, 6 (1905), No. 9, pp. 383-387*).—For the rapid determination of the fineness of sulphur to be used in combating the powdery mildew of the grape the author recommends an adaptation of the Schöne soil elutriator, and gives the results of a number of tests of this apparatus, comparing the results with those obtained by other methods.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

International catalogue of scientific literature. N—Zoology (*Internat. Cat. Sci. Lit., 1905, pts. 1, pp. VIII+432; 2, pp. XI+963*).—The third annual issue of the literature on zoology is divided into 3 parts, of which the first part contains a general account of the system pursued in classifying zoological literature and an author index on literature published since 1901, but particularly for the year 1903. Part 2 contains a subject index of literature relating to invertebrate animals.

The night hawk, A. MERAZ (*Com. Par. Agr. [Mexico], Circ. 40, pp. 4, fig. 1*).—The habits of this bird are briefly discussed with particular reference to its agricultural importance. The night hawk is almost strictly insectivorous and a large proportion of the insects upon which it feeds is injurious. In an examination of 87 stomachs of night hawks, 20,000 ants were found in addition to various other insects.

Birds that eat the cotton-boll weevil, A. H. HOWELL (*U. S. Dept. Agr., Bur. Biol. Surrey Bul. 25, pp. 22*).—Observations on birds in the region where the cotton-boll weevil prevailed in 1905 have added somewhat to the list of those known to feed upon this pest. At present 28 species are recorded as feeding upon the cotton-boll weevil to some extent and part of them in summer and others during the winter months. Notes are given on the importance of various birds in this work, including orioles, blackbirds, meadow lark, night hawks, sparrows, fly catchers, quail, etc. Details of observations at different points are also presented together with a tabulation of the results obtained by the examination of birds' stomachs.

Fifth report of the State entomologist, W. E. BRITTON (*Connecticut State Sta. Rpt. 1905, pt. 4, pp. XV + 189-262, pls. 12, figs. 7*).—A brief statement is

made of the organization, equipment, lectures, correspondence, and nursery inspection of the entomological department. During the year under report about 6,000 trees were sprayed for scale insects and attention was also given to tobacco insects, mosquitoes, insecticides, elm-leaf beetle, onion maggot, cutworms, San José scale, etc.

More than 6,000 pear, peach, and apple trees located in 5 towns were treated for San José scale. The spray mixtures included lime-sulphur and lime-sulphur-salt washes boiled with external heat or self-boiled and kerosene-limoid emulsion. The lime-sulphur mixture was prepared according to the formula 20-14-40. The average efficiency ranged from 88.3 to 94.9 per cent, being lowest in the case of kerosene limoid and highest after the use of a lime-sulphur and sodium-sulphid wash. The cost of the various washes ranged from 54 cts. to \$1.66 per 40 gal., being lowest in the case of lime-sulphur wash and highest with the kerosene limoid. The author considers all of the mixtures as fairly satisfactory. No appreciable benefit was observed from the addition of salt to the lime-sulphur wash.

A list is presented of insects collected from the flowers of fruit trees and plants and notes are also given on mosquitoes, woolly maple scale, tussock moth, scale insects of Connecticut, gypsy moth, and Indian meal moth, as well as short paragraphs on a number of less important injurious insects. The apple maggot was found infesting huckleberries and the thistle butterfly was observed as an enemy of hollyhocks.

Report of the entomologist, E. H. SELLARDS (*Florida Sta. Rpt. 1905, pp. 17-28*).—During the year under report considerable of the entomologist's time has been taken with identification of insects and nursery inspection. The desirability of a State inspection law is urged. Considerable damage was done to potatoes by a potato maggot (*Pegomyia fusciceps*). This pest tunnels through the potato causing a destruction of its substance and leading to the development of decay. It is suggested that the use of commercial fertilizers may assist in repelling this insect. Some injury was also done to potatoes by ants which attack the stems. The common potato beetle is also reported as having at last been found in Florida. The injuries thus far done in Florida are not very serious.

Considerable attention is given to a discussion of the mosquitoes of Florida and notes are presented on white fly, cottony cushion scale, cotton stainer, and *Pachynus distans* which attacks the roots of the grape fruit.

Report of the entomologist, J. B. SMITH (*New Jersey Stat. Rpt. 1905, pp. 527-687, pls. 7, figs. 39*).—In combating the San José scale the author recommends that spraying be done as soon as the fruit is off and the foliage is mature in the fall. Preference is given to soluble oils as an insecticide although other kerosene mixtures and lime-sulphur-salt are also recommended. An account is presented of the efforts put forth in Newark and other cities of New Jersey in controlling shade-tree insects under the direction of commissions appointed for that purpose. Notes are also given on the oyster-shell bark-louse, elm-leaf beetle, gypsy moth, brown-tail moth, pear psylla, cornstalk borer, rose chafer, Asiatic lady bird, tussock moth, peach soft scale, cottony maple scale, and other injurious insects.

During the season successful experiments were carried out with a lime-sulphur-caustic-soda mixture applied in the first week of April for destroying San José scale. A brief summary is also presented of entomology in the crop bulletin and on observations made in the experimental orchard of the station. In experiments on cranberry insects it appeared that *Eudemis vacciniana* may be partly destroyed in the egg stage by flooding the cranberry beds for 2 weeks

under 18 in. or more of water at a temperature of 60° F. Reflooding of the beds for 24 hours after the eggs have hatched will destroy nearly all of the larvae. It appears that the natural enemies of the cottony maple scale may be largely depended upon to control this pest. Brief notes are given on the results of practical tests with a number of proprietary insecticides.

A report is given on the mosquito investigation during 1905 (pp. 655-689). In this work particular attention was given to determining the beneficial results from previous drainage work and other remedial measures and a further survey of the study to determine the work still to be done. Estimates are given of the cost of operations which will be carried on in utilizing the State appropriations for mosquito work.

Report of the government entomologist, C. FULLER (*Natal Dept. Agr., Rpt. Govt. Ent., 4 (1903-4, pp. 47, pls. 8, figs. 3)*).—A general account is given of the routine work of the office with notes on lectures given by the entomologist and travel done in various parts of the colony. An unknown species of *Carpocapsa* is referred to under the name of Natal codling moth and brief notes are given on its habits. It attacks peaches, Chinese guavas, oranges, and mandarins. The pest may be partly controlled by removing infested fruits, but spraying with Paris green combined with Bordeaux mixture is also of great value. An account is also given of the true codling moth, fig curculio (*Melotrypes turritus*), mango weevil, *Bengalia depressa* which attacks man, dogs, rabbits, and other animals; Mediterranean fruit fly, mosquitoes, *Bagrada hilaris*, scale insects, locusts, rhubarb blight, English sparrow, and various other pests. Formulas are also presented for the preparation of certain insecticides.

Report of the government entomologist, C. FULLER (*Natal Dept. Agr., Rpt. Govt. Ent., 5 (1904-5), pp. 17, pl. 1*).—The routine inspection and other work of the office for the year is briefly described. A statement is also given regarding the investigation of fruit fly parasite. It is believed that the parasite which has been found in Brazil does not promise to be of much assistance in the control of the fruit fly. Copies are also given of certain legislation relating to plant diseases, cotton diseases, weeds, fruit inspection, etc. During the year under report arsenical insecticides were extensively used in the control of locusts, and this work gave good results.

Entomological division, W. R. DEWAR (*Orange River Colony, Dept. Agr., Ann. Rpt., 1 (1904-5), pp. 183-238, figs. 10*).—The matters discussed in this report include the use of arsenicals and other methods for combating locusts, the inspection of nursery stock so as to prevent the introduction of injurious insects, the distribution of lady beetles, the investigation of mosquitoes and ticks, as well as a large variety of insects injurious to garden and field crops. A brief account of birds as related to agriculture is given by C. M. Johnston (pp. 221-228), and the subject of injurious weeds is also discussed (pp. 229-238).

The entomological section, C. B. SIMPSON (*Transvaal Agr. Jour., 4 (1906), No. 15, pp. 619-626, pls. 4*).—*Ophiusa catella* is injurious during its larval stage to the leaves of castor-oil beans while the adults puncture peaches, thereby greatly injuring the crop. Notes are given on the insect in its various stages and on its natural enemies. In small plantations of castor-oil beans hand-picking is quite satisfactory, while on large plantations spraying is necessary, and for this purpose Paris green or some other arsenical is recommended. Notes are also given on *Heliocoprís hamadryas* and the cigarette beetle.

Report on injurious insects in Finland, E. REUTER (*Landtbr. Styf. Meddel., 50, 1905, pp. 27*).—The year under report was unusually cloudy and cold and therefore somewhat unfavorable to the multiplication of insects. As in previous reports, the author classifies his discussion of injurious insects according to the plants affected. Grasses of pastures and meadows were injured to some extent

by *Charax graminis* and a number of other insects which produce blasting of the heads. The larvæ of crane flies were also observed in considerable numbers. Brief notes are given on wireworms, snails, fruit fly, and other enemies of cereals. Among the garden pests the cabbage and beet-root maggots deserve special mention. Potato scab also prevails quite widely. The life history and habits of *Uropoda obnoxia* are described. The most injurious insects on fruit trees during the year were codling moth, *Argyresthia conjugella*, gypsy moth, and pear-leaf blister-mite. In combating the gypsy moth, lead arsenate was used with good results. Brief notes are also given on insects injurious to trees and ornamental plants.

Entomological notes, J. KOTINSKY (*Hawaii, Forester and Agr.*, 2 (1905), No. 10, pp. 295-299).—*Siphanta acuta* is found in large numbers on coffee and is believed to assist in the distribution of the brown eye-spot disease of coffee. Notes are given on a parasite of the egg of this pest and on *Scutellista cyanca* and fleas in relation to the distribution of the disease.

Annual report for 1905 of the zoologist, C. WARBURTON (*Jour. Roy. Agr. Soc. England*, 66 (1905), pp. 178-191, figs. 2).—The bud mite of the currant still continues to occupy considerable attention. The author believes that there is no likelihood of exterminating the pest except by destroying infested bushes. Notes are given on the habits, life history, and means of combating *Chermes laricis*, asparagus beetle, *Hadena pisi*, *Siphonophora fodiens*, various species of Tarsionemus, and other injurious insects.

The monthly bulletin of the division of zoology, H. A. SURFACE (*Penn. Dept. Agr., Mo. Bul. Div. Zool.*, 3 (1906), No. 12, pp. 367-404, pls. 2).—Good results are reported from the use of poisoned bran in destroying cutworms. An announcement is made regarding the forthcoming brood of 17-year locusts. Notes are also given on the present distribution and injuries caused by San José scale. The value of sulphur for insecticide purposes is briefly discussed with notes on the process of manufacturing it and the various qualities of sulphur which may be obtained. Notes are also given on the dates of last killing spring frosts in Pennsylvania for a number of years, fumigating houses for fleas, and other subjects.

The monthly bulletin of the division of zoology, H. A. SURFACE (*Penn. Dept. Agr., Mo. Bul. Div. Zool.*, 4 (1906), No. 1, pp. 40, figs. 2).—In experiments with the asparagus beetle it is found that this pest may be controlled in large part by the application of arsenicals, such as Paris green and arsenate of lead, but that such applications should not be made too soon before the asparagus is cut for food. The preparation recommended by the author includes 2 oz. of lead arsenate and 5 oz. of resin soap in 3 gal. of water. Formulas are also given for various fungicides and insecticides, together with notes on methods for controlling some of the more important insect pests.

National control of introduced insect pests, E. D. SANDERSON (*Pop. Sci. Mo.*, 68 (1906), No. 5, pp. 431-439).—The questions raised by the great damages caused by the boll weevil, gypsy moth, and brown-tail moth are discussed with particular reference to the interference of the National Government in the control of these pests. The case is believed to be analogous to those in which, for the purpose of protecting human health against various plagues, the Federal Government has felt called upon to interfere. Various instances are cited in which this Department has taken a hand in the suppression of animal plagues, particularly the recent outbreak of foot-and-mouth disease in New England.

Catalogue of recently described coccidæ, J. G. SANDERS (*U. S. Dept. Agr., Bur. Ent. Bul.*, 12, tech. ser., pt. 1, pp. 18).—Several additions to the species of Coccidæ have been made since the publication of Mrs. Fernald's catalogue in

Massachusetts Station Bulletin 88 and are here arranged under 9 genera, 137 species, and 22 varieties.

Formalin as a reagent in the preparation of some soft-bodied Coccidæ, E. E. GREEN (*Ent. Mo. Mag.*, 2. ser., 17 (1906), No. 198, pp. 129, 130).—Some difficulty has been experienced in preserving Coccidæ, especially the soft-bodied species, for subsequent study. The chitin of the skin often fails to hold its form, and the dermal cells and other characteristic features may become obliterated. The author accidentally discovered that formalin in a 3 per cent solution preserves these features in excellent condition.

The bionomics of grain weevils, F. J. COLE (*Jour. Econ. Biol.*, 1 (1906), No. 2, pp. 63-71).—The experiments reported in the present paper were made on the common grain and rice weevils. It appears that moisture under a temperature of 80° F. is favorable to the life of adult grain weevils but that the temperature of 80° F. without the moisture is quite fatal to the beetles. A non-ventilated atmosphere at a temperature of 80° F. charged with water vapor furnishes favorable conditions for the life of the beetles. Experiments in withholding oxygen from the beetles indicate that they may thrive well in an atmosphere containing 80 per cent of carbon dioxide. It is obviously impossible therefore to destroy them by preventing ventilation.

Animals injurious to sugar beets, J. JABLONOWSKI (*A cukorrépa állati ellenségei. Budapest: Hungarian Sugar Beet Assoc.*, 1906, pp. 288, figs. 65).—The sugar beet industry of Hungary is of sufficient importance to justify an elaborate study of the insect enemies of this plant. The author has made observations on the important insect enemies of sugar beets, and in the present volume presents the results of his study, together with the results of other investigators who have worked along the same line. The insects discussed in the volume include a long list of species injurious to the various parts of the sugar beet. Myriapods, mites, and related species of animals are discussed. Among the more important insects mention may be made of *Cleonus punctiventris*, *C. pedestris*, *Haltica oleracea*, various species of wireworms, *Aphis papaveris*, caterpillars injurious to leaves, especially webworms, *Pegomyia hyoseyami*, related species of maggots, etc.

Insect pests of cotton in India, H. MAXWELL-LEFROY (*Agr. Jour. India*, 1 (1906), No. 1, pp. 49-61, pls. 4).—On account of the large annual production of cotton in India the insect pests of this crop assume considerable economic importance. In the present article particular attention was given to cotton aphid, *Dysdercus cingulatus*, bollworms (*Gelechia gossypiella*, *Earias fabia*, and *E. insulana*), cotton-stem borer, and cotton-stem weevil. These pests are considered the most important ones affecting cotton in India, and it is estimated that they cause the destruction of about one-tenth of the crop. Fortunately the remedies for these pests are comparatively simple, and the main problem in the control of the insects consists in educating the natives of India so that they will recognize the nature of the pests and the necessity for taking some insecticide measures.

The principal insects attacking the cocoanut palm, II. C. S. BANKS (*Philippine Jour. Sci.*, 1 (1906), No. 3, pp. 211-228, pls. 10).—In the present paper the author discusses certain species of lepidoptera and coccidæ which attack the cocoanut palm. In this account particular attention is given to *Thosca cincreumarginata*, *Padraona chrysozona*, *Aspidiotus destructor*, etc. It is suggested that spraying with lime-sulphur wash or kerosene emulsion would serve to protect young cocoanut trees against attacks of scale insects.

Moth borer in sugar cane, maize, and sorghum in western India, H. MAXWELL-LEFROY (*Agr. Jour. India*, 1 (1906), No. 2, pp. 97-114, pls. 2).—A number of insects are commonly referred to as moth borers of the sugar cane, but the

one which is the most injurious in western India and which is discussed in the present article is *Chilo simplex*. This species is quite closely related to *C. auricilia*, which attacks sugar cane in Bengal. The life history of the sugarcane moth borer is described in detail. The moths fly at night and hide among the leaves or rubbish during the day. Cane, maize, and sorghum are the principal plants attacked by the pest. In the cane the insect is injurious chiefly during the young stage of the plant before the joints are formed. All parts of corn are attacked, including the cob, and sorghum is injured in all its stages. The eggs of the moth borer are parasitized to some extent, but artificial remedies must be adopted in combating it. The species seems to be generally distributed throughout India. Not all of the remedies recommended for sugarcane borers in various parts of the world are applicable to this pest. The two best suited for controlling it are the destruction of young cane tops as soon as it is noticed that they are infested and the use of corn and sorghum for trap crops.

The melon fly, D. L. VAN DINE (*Hawaii, Forester and Agr.*, 3 (1906), No. 4, pp. 127-129).—*Dacus cucurbitar* attacks all of the common cucurbits as well as string beans, tomatoes, mangoes, and papaya. Notes are given on the life history of the pest. The insect attacks the vines as well as the fruit and causes a rapid decay especially in wet weather. All infested melons and vines should be collected regularly during the season and burned or otherwise destroyed, and no such material should be left in the field after harvesting. The insects may also be prevented from doing damage to the growing crop by covering young melons with paper, straw, or a piece of gummy sack.

Codling moth parasites, W. W. FROGGATT (*Agr. Gaz. N. S. Wales*, 17 (1906), No. 4, pp. 387-395).—Attention is called to the fact that the codling moth has long been known to be an important enemy of the apple and that many of its parasites must have had their present habits for hundreds of years. Detailed notes are given on some of the more important parasites of codling moth, including *Trichogramma pretiosa*, *Goniozus antipodum*, *Ephialtes carbonarius*, and species of *Parisemus* and *Pteromalus*.

The Brazil fruit fly parasites, C. P. LOUNSBURY (*Agr. Jour. Cape Good Hope*, 28 (1906), No. 4, pp. 538-540).—The author requested Professor Hempel of the Agronomic Institute of São Paulo to carry on further observations regarding the value of the fruit fly parasite found in that region. According to the latest report of Professor Hempel, it appears that there is no hope of obtaining any efficient help in controlling the fruit fly by the use of this parasite.

The grape curculio, F. E. BROOKS (*West Virginia Sta. Bul.* 100, pp. 211-249, pls. 8).—Two insects quite commonly feed on the fruit of the grape in West Virginia. These are the grape-berry moth and the grape curculio (*Craponius inuqualis*). The grape curculio has received little attention from entomologists and was, therefore, made the subject of a continued study by the author for a long period. A circular letter of inquiry sent out to various vineyardists elicited the information that the grape curculio is quite widely distributed throughout the State and does considerable injury. The curculio is a native insect and appears to have fed on wild grapes for centuries. The grape curculio is described in its various stages and notes are given on its life history. The eggs are laid in punctures made in the fruit and hatch within 4 to 6 days, after which the larva feeds upon the fruit, leaving it later for pupation. The pupa may be found in various locations, especially just under the surface of the ground.

This insect appears to feed only on the grape. It winters over in the adult form and the hibernated beetles appear during the last of May. Apparently there is no connection between the injury from this insect and grape rot. Some

little difference is observed in the extent to which different varieties of grapes are attacked. The grape curculio is preyed upon by a number of insect enemies. Among the various methods which may be adopted in controlling this pest, spraying is of chief importance. It appears to be possible by means of arsenical sprays to control the pest quite completely. For this purpose 4 oz. of Paris green and 4 lbs. of lime in 50 gal. of water are quite satisfactory. Grapes may also be protected by surrounding each cluster with a paper bag. If this method of combating the pest is adopted it may be estimated that pins will cost 15 cts. a thousand, bags 85 cts. per thousand, and the work about \$1 per thousand bunches. This method not only has the advantage of protecting grape clusters against the curculio, but also prevents rot, and the grapes have a fine appearance. It is recommended for home vineyards and commercial growers who cater to a fancy trade. The insects may also be controlled to some extent by jarring and by collecting infected grapes. A brief bibliography relating to this insect is appended to the bulletin.

Arsenical treatment of grape flea beetles, L. TRABUT (*Bul. Agr. Algérie et Tunisie*, 12 (1906), No. 6, pp. 112-114).—Some difficulty has been experienced in the use of ordinary arsenicals for destroying this pest since the grape foliage is injured by applications strong enough to destroy the insects. Within recent years, however, better results have been obtained from the use of lead arsenate since this material is almost equally poisonous to the insects and not soluble and therefore not injurious to the grape foliage.

The Bombay locust (*Acridium succinctum*), H. MAXWELL-LEFROY (*Mém. Dept. Agr. India, Ent. Ser.*, 1 (1906), No. 1, pp. 112, pls. 13).—The present account contains a report of investigations on *Acridium succinctum* in India during the years 1903-4. In various parts of the Bombay Presidency this locust prevails in large numbers where it feeds on grasses, sorghum, and various other crops. In some cases the migratory locust (*A. peregrinum*) appeared after the other species had left. The winged locust appears during October, undertakes migration during November, remains largely in forests from December until March 20, shows other migratory movements from March 20 to May 20, after which they become scattered. The life history of the insect is discussed in detail. In combating this species, various remedies have been tried, including the use of arsenical poisons. Experiments were carried on by G. K. Walker in which the effect of eating forage plants treated with arsenicals was tested on cattle. In some instances unfavorable results were obtained, since arsenic taken repeatedly in small doses exercises a cumulative poisonous effect. The general programme of eradication of locusts as recommended by the author includes a study of the movements of the swarms during the first migrating period, driving the locusts out of crops and destroying them, particularly at night and at the time when the young hoppers first appear.

A hopperdozer, P. K. BLINN (*Colorado Sta. Bul.* 112, pp. 8, figs 5).—During recent years alfalfa has been greatly injured by grasshoppers in various parts of Colorado, and for the last few years these pests have apparently been increasing in numbers. Last year the injury from grasshoppers was unusually severe. Various methods were adopted, such as driving and the use of poisonous baits, but without much success. Experiments were carried out by the author in a number of localities during which a hopperdozer costing about \$4.50 for construction was tested to determine its value when hauled over the field behind the mowing machine. It was found that 1 horse could be attached to the side in such a manner as not to frighten the grasshoppers away from the hopperdozer. The hopperdozer was mounted on wheels in order not to catch in the hay. The use of this machine on a 6-acre field of alfalfa resulted in catching between

9 and 10 bu. of grasshoppers estimated at the rate of 30,000 grasshoppers per bushel. In one instance on another field success was had in using the hopper-dozer without any oil film on the water. The grasshoppers fell into the water, from which they were unable to escape for several minutes. At the end of each round they could be collected and placed in a can, after which they were used for poultry food.

A new book and leather pest, J. KOTINSKY (*Hawaii, Forester and Agr.*, 3 (1906), No. 4, pp. 117, 118).—*Cutorama mexicana* has been found in leather goods and books in Kona and on the island of Kauai. This pest may best be prevented by extreme cleanliness, frequent dusting and moving of books and leather goods, or if these preventive means fail, resort may be had to fumigation with bisulphid of carbon.

Note on the deposition of the eggs and larvæ of *Æstrus ovis*, W. E. COLLINGE (*Jour. Econ. Biol.*, 1 (1906), No. 2, pp. 72, 73).—Some controversy has prevailed in regard to the question whether sheep botflies deposit eggs or living larvæ in the nostrils of the sheep. According to the author's observations this depends somewhat on the weather. When conditions are favorable the fly deposits eggs, but if the weather is such that the females must remain inactive for some days the eggs may hatch within the body before being deposited.

On the life history of the ox warble flies *Hypoderma bovis* and *H. lineata*, A. D. IMMS (*Jour. Econ. Biol.*, 1 (1906), No. 2, pp. 74-89).—The habits and life history of these insects are discussed in detail and a brief bibliography of the subject is also given. According to the author's observations it is practically impossible to decide at the present time in favor of any one of the three current theories in regard to the life history of *Hypoderma bovis*. It may be that the larvæ, immediately after hatching, eat their way through the hide and remain in the subcutaneous tissues until they are fully grown. On the other hand, the larvæ may wander extensively through the tissues of the host, even entering the spinal canal, and may then return to the subcutaneous tissues where they reach maturity. Again the larvæ may be taken into the esophagus from which they bore through the tissues and reach the skin. The usual remedies recommended for these pests are described.

The rôle played by biting flies in the spread of trypanosomiasis, J. D. E. HOLMES (*Jour. Trop. Vet. Sci.*, 1 (1906) No. 2, pp. 119-126).—The author calls attention to the fact that the idea that flies and other biting or blood-sucking insects act as carriers of disease is as old as the art of medicine, and that it is more difficult to reject than to accept it. Evidence is presented, however, on the basis of 3 years' observations and experiments tending to show that the rôle of biting insects in the transmission of trypanosomiasis in horses has been at least greatly exaggerated. During a period of 3 years infected ponies were kept in contact with healthy ponies in a stable where various species of horse flies were very numerous. The author frequently observed these flies sucking blood from an infected pony and later attacking healthy ponies. A number of the flies were examined and the horse blood in them was found to contain the organism of the disease. In no case, however, was the disease transmitted from an infected to a healthy animal. Other evidence along the same line is presented. The author believes, therefore, that "the theory that biting flies directly transmit the disease in cases of natural infection looks less probable and less worthy of consideration from a practical standpoint."

The anatomy and physiology of the tsetse fly, F. STUHLMANN (*Pflanzer*, 1905, Nos. 24, pp. 369-384; 25, pp. 385-412).—The observations of the author were chiefly confined to *Glossina fusca*, *G. tachinoides*, and *G. palpalis*. Detailed anatomical descriptions are given of the mouth parts, salivary glands, alimen-

tary tract, the digestive processes, and other physiological functions of these insects. An analytical table was presented for the identification of species of the genus *Glossina*.

The action of *Aspergillus niger* and *A. glaucus* on the larvæ of *Culex* and *Anopheles*, B. GALLI-VALERIO and JEANNE ROCHAZ-DE-JONGH (*Centbl. Bakt. [etc.], 1. Abt., Orig., 40 (1906), No. 5, pp. 630-633*).—The authors carried on experiments with mosquito larvæ in glass vessels in which spore-bearing cultures of *Aspergillus niger* and *A. glaucus* were mixed with the water. The larvæ became infected with the spores of these molds and the infection persisted into the pupal and adult stages. An attempt was made to experiment along the same line under field conditions, but the results were not satisfactory for the reason that it was found very difficult to observe the effect of the molds with certainty. Apparently the method is not practical under field conditions.

Bordeaux mixture and Paris green, F. SHERMAN, JR., and R. S. WOGLUM (*N. C. Dept. Agr. Ent. Circ. 17, pp. 14, figs. 2*).—On account of the effectiveness and general applicability of the combination of Paris green with Bordeaux mixture in fighting both insect and fungus diseases, the authors have prepared an account of this mixture with notes on the formula, method of preparation, use, and applicability in treating the insect and fungus enemies of fruits and garden crops.

Annual report of the Beekeepers' Association of the Province of Ontario, 1905 (*Ann. Rpt. Beekeepers' Assoc. Ontario, 1905, pp. 72*).—This report contains an account of the proceedings of the twenty-sixth annual meeting of the Ontario Beekeepers' Association held in Toronto, November 15-17, 1905. At this meeting a considerable list of papers were read and were followed by interesting discussions. In the president's address, H. G. Sibbald called attention to the advantages of beekeepers from attending such meetings and exchanging views on the various problems of beekeeping.

F. C. Harrison also discussed the methods of diffusing apicultural knowledge (pp. 8-10). It was urged that bee journals should contain every month advice to beginners regarding the common troubles which they are likely to meet with in caring for bees.

R. H. Smith called attention to the necessity of systematic advertising in the successful marketing of honey (pp. 16-18). Complaint is frequently made that the demand for pure comb honey is not sufficiently active. It was suggested that this is partly due to a lack of judicious advertising on the part of bee raisers and carelessness in the packing and marketing of the product.

F. T. Shutt reported a number of experiments in apicultural work (pp. 23-26). Honey consumers sometimes complain of the granulation of honey and believe that this indicates some impurity. Attention was called to the fact that pure honey will granulate or candy even if it is maintained in cold storage at a temperature of 40° F. A large number of chemicals were tested in attempts to devise a successful method for bleaching wax. No good results were obtained. Brief notes were also given on the nature of honeydew on trees.

The report also contains short articles on Production of Comb Honey, by R. Lowey (pp. 26-28); Amendments to the Foul Brood Act, by F. J. Miller (pp. 30-33); A Method of Preventing Swarming, by J. Fixter (pp. 39-41); Beekeeping in Canada and Jamaica, by A. Laing (pp. 49-53); Out Apiaries, by D. Nolan (pp. 61, 62); and other notes and discussions.

Note on bacteria pathogenic to the silkworm, S. SAWAMURA (*Bul. Col. Agr., Tokyo Imp. Univ., 7 (1906), No. 1, p. 106*).—In a study of flacherie of silkworms the author finds that the disease may be caused by a number of bacteria,

including various species of *Proteus*, *Micrococcus pyogenes aureus*, *Bacillus coli*, *B. ellenbachii*, *B. ferrugineus*, *B. fuchsianus*, *B. megatherium*, *B. megatherium bombycis*, *B. mycoides*, *B. pyocyaneus*, *B. rubefaciens*, and *B. viridans*.

FOODS—HUMAN NUTRITION.

Cooking quality of potatoes (*Jour. Bd. Agr.* [London], 13 (1906), No. 1, pp. 47-49).—Experiments on the cooking quality of potatoes, by which is meant the appearance, texture, and flavor after cooking, carried on at the Edinburgh and East of Scotland Agricultural College, are briefly summarized.

Of the different varieties Langworthy is classed as excellent; Twentieth Century, White Blossom, and British Queen as very good, and Pink Blossom, Factor, Up-to-Date, and King Edward VII as good.

"The varieties in the group classed good are at least equal to Up-to-Date in quality, and some of them surpass it. Quality in potatoes, of course, will vary considerably with soil and cultivation. On some farms the varieties classed here as good would be very good indeed, while on others they would be no more than tolerable. Their defect is a slight tendency to softness in the heart. The three heaviest cropping varieties fall into this group.

"All the varieties styled very good were very satisfactory as regards quality, but when broken they fall short of the firm flaky texture which is characteristic of the Langworthy, and which, along with fine flavor, entitles this variety to be ranked as excellent."

The cooking of starches in cereals, GRACE P. MULBERRY (*Ill. Agr.*, 10 (1906), No. 7, pp. 238, 239).—A brief summary of investigations on the effect of different methods of cooking upon the quality and flavor of cereal breakfast foods. In general, the experiments showed that in order to soften the cellulose and gain the maximum flavor and palatability cooking should be continued for a considerable time (5 hours in the experiments reported). A more economical method is to cook the cereals for at least 2 hours on the day before they are required, cover the top with water to prevent drying, and allow them to stand over night. In the morning the breakfast cereal may be warmed in a double boiler "and does not of necessity become lumpy or mushy if stirred with a fork. The richness in flavor and the softness of the cellulose will well repay one for cooking cereals for 2 hours or more."

Preservation of foods on a commercial scale, X. ROCQUES (*Les industries de la conservation des aliments*, Paris: Gauthier-Villars, 1906, pp. XII + 506, figs. 112).—An extended discussion from an historical and commercial standpoint of preserving food by heat, cold, drying, and by the use of antiseptics. A special chapter is devoted to the preservation of eggs. The volume as a whole constitutes a handbook of the preserving industry. There are prefaces by P. Brouardel and A. Muntz.

A practical guide to cookery in West Africa and the Tropics, ADELAIDE M. COCKBURN (*London: Scientific Press, Ltd.*, [1905], pp. XII + 160).—On the basis of experience the author gives direction for the preparation of a large number of dishes suitable for the Tropics, having in mind the available food supply. The volume contains considerable information regarding meats, vegetables, fruits, etc., found in the West African markets.

Food analyses, C. F. JURITZ (*Rpt. Senior Anal. Cape Good Hope, 1904*, pp. 6-24, *dgm. 1*).—Under the Food Adulteration Act a number of samples of milk, wine, and spirits, vinegar, cream, drugs, etc., were examined. In preserved egg yolk put up in bottles large amounts of boric acid were found. A partial analysis is quoted of Cape Bush tea (*Cyclopiu genistoides*), a material frequently

used in the rural regions of Cape Colony for the preparation of an infused beverage. The material contained neither alkaloids nor glucosids.

Adulteration of food, W. J. GERALD (*Rpt. Inland Rev. Canada, 1905, pt. 3, pp. 101*).—Data regarding the inspection of foods, drugs, and fertilizers by Dominion chemists are summarized.

Of 75 samples of ground mustard 8 were genuine, 11 doubtful, and the remainder adulterated. None of the flours examined were adulterated. Of 18 samples of bread 2 were doubtful and 5 gave decided reaction for alum. Of 45 samples of molasses 1 was adulterated and 5 considered doubtful.

Other analyses reported in detail in appendixes have been published in bulletins of the Laboratory of the Inland Revenue Department, Ottawa, and previously noted.

Elements of applied microscopy, C. E. A. WINSLOW (*New York: John Wiley & Sons; London: Chapman & Hall, Ltd., 1906, pp. XII+183, figs. 60; rev. in Amer. Jour. Pharm., 78 (1906), No. 5, p. 238*).—This is an introductory textbook which takes up among other questions the microscopy of common starches, and foods and drugs and their adulterants.

The testing of yeast employed in bread making (*Pure Products, 2 (1906), Nos. 4, pp. 187-190; 5, pp. 226-230*).—Differences between brewers' yeast and compressed yeast are pointed out. The compressed yeast consists of the so-called top fermentation yeasts with water removed, so that the yeast may be conveniently shipped and stored. It is stated that the chief trouble arising in bread making from the use of brewers' yeast is due to the almost entire absence of diastatic enzymes and to the larger proportion of trypsin which it secretes. The trypsin causes cleavage of proteids, and so the glutenin of the dough becomes softened to such an extent that it fails to retain carbon dioxide. When compressed yeast is used the glutenin remains tough and retains gas. In testing compressed yeast such characteristics as color, odor, taste, and keeping quality should be taken into account. The yeast should also be examined for adulteration with bottom-fermenting brewers' yeast, and methods of making the tests are pointed out. The fermenting power should also be determined, and the Hayduck method is considered most satisfactory for the purpose.

The decomposition of French mustard by bacteria and its prevention, A. KOSOWICZ (*Ztschr. Landw. Versuchsw. Oesterr., 9 (1906), No. 3, pp. 111-116, pl. 1*).—Two forms of bacteria were isolated which were regarded as the main cause of decomposition of bottled mixed mustard. Other changes were attributed to mechanical and chemical causes; for instance the separation of the liquid from the solid portion and the rancidity of mustard fats. Sterilization of the bottled mustard is recommended as a preventive, as well as the use of well stoppered bottles and mixing the mustard with 4 or 5 per cent vinegar and allowing it to stand 12 hours before bottling.

A study of three vegetarian diets, D. N. PATON and J. C. DUNLOP (*Proc. Roy. Soc. Edinb., 25 (1904-5), pt. 7, pp. 498-506*).—Two of the 3 dietaries studied included milk and eggs as well as vegetable foods, while the third was made up entirely of bananas. The subject of the fruitarian dietary, a man weighing 52 kg., consumed during the 5 days he was under observation 9 lbs. 8 oz. of this fruit. The food value of the diet was only 7.5 gm. protein, 0.7 gm. fat, and 199.8 gm. carbohydrates per day with a fuel value of 856 calories. During the entire period considerably more nitrogen was excreted than was consumed, the amount being equivalent to a daily loss of 19.8 gm. of tissue protein, or about 100 gm. of flesh. These values are very similar to those noted in starvation. The total amount of nonurea nitrogen was less than normal and the preformed ammonia was very small.

In the other 2 diets the amount of protein and energy was sufficient for the maintenance of health and muscular vigor, but the cost was considerably in excess of "that for which the laboring classes in town or country are able to procure an equally satisfactory diet."

"The study of the ordinary diets of the laboring classes in all countries seems to show that whenever possible a diet is secured which will yield something over 3,000 calories of energy and over 100 gm. of proteids per man per diem. It is improbable that so many different races should have made the same mistakes in the essential elements of their very varied diets."

Results of digestion experiments with milk powder, F. KRULL (*Milchw. Zentbl.*, 2 (1906), No. 4, pp. 165-173).—A summary of analytical data and the results of artificial and natural digestion experiments led the author to conclude that milk powder is readily and thoroughly digested and may be used in infant feeding and in the household in many ways.

Nitrogenous metabolism in normal individuals, J. M. HAMILL and S. B. SCHRYVER (*Jour. Physiol.*, 34 (1906), No. 3, *Proc. Physiol. Soc.*, 1906, pp. X-VII).—Six-day experiments with 7 subjects showed that on an average the nitrogen excreted per day was 13.5 gm. Allowing for a loss of 10 per cent in the feces, this is equivalent to 92 gm. of protein per person per day. The ratio of uric-acid nitrogen to total nitrogen was fairly constant, being 1.54 on an average.

Carbohydrate combustion in the animal body, J. STOKLASA (*Ber. Deut. Chem. Gesell.*, 38 (1905), No. 2, pp. 664-670).—Studies of the effect of expressed meat juice on carbohydrates led to the conclusion that the energy-yielding processes in cell protoplasm are brought about by the enzyme lactolase which forms lactic acid from carbohydrates, and by alcoholase, which forms alcohol and carbon dioxide. The secondary products which are formed by further cleavage are produced only when oxygen is present. The enzymes which cause such cleavage are acetolase and formilase. The cleavage products capable of oxidation are converted into carbon dioxide and water by the oxygen of the air.

The chemistry of digestion in the animal body. III, Proteid cleavage in the digestive tract, E. S. LONDON (*Ztschr. Physiol. Chem.*, 47 (1906), No. 4-6, pp. 368-375).—In the middle portion of the small intestine alanin and aspartic acid were noted as cleavage products in addition to those reported by other observers when meat was fed. The experiments were made with dogs. The author believes that it is possible to determine proteid cleavage quantitatively in the animal body, and that Fischer's ester methods may be used with good results in studying products of animal digestion.

Concerning the extractive material of muscular tissue. III, Methylguanidin, W. GULEWITSCH (*Ztschr. Physiol. Chem.*, 47 (1906), No. 4-6, pp. 471-475).—Methylguanidin, a constituent of meat extract, the author concludes is formed by autolysis either after death or, more probably, during life and is to be regarded as an oxidation product of creatin or creatinin. For earlier work see E. S. R., 17, p. 683.

Protein assimilation in the animal body, E. ABDERHALDEN and P. RONA (*Ztschr. Physiol. Chem.*, 47 (1906), No. 4-6, pp. 397-403).—When the body is supplied with a large excess of protein the authors conclude, from their experiments, that it has the power to select those which are best suited for the formation of body proteids. The experiments were made with dogs, and the balance of income and outgo of nitrogen was determined.

A law of growth reiterated, G. LUSK (*Amer. Jour. Physiol.*, 15 (1906), No. 3, *Proc. Amer. Physiol. Soc.*, 18 (1905), pp. XVII, XVIII).—The law which the author formulates is that in the normal development of young of the same age and species a definite percentage of the energy content of the food is required for growth irrespective of the size of the individual.

Demands for heat and the calorimetric value of a ration with respect to temperature or climate, J. LEFÈVRE (*Compt. Rend. Soc. Biol. [Paris]*, 60 (1906), No. 15, pp. 750-753).—Using a special form of calorimeter, which he has elaborated, the author measured the heat output of the body at temperatures ranging from -1 to $+20^{\circ}$ C. The results, which included the calculated latent heat of excreted water vapor, ranged from 1,900 calories at the higher temperature to 5,400 calories at the lower temperature per 24 hours for a man wearing medium-weight clothing. This indicates, in the author's opinion, the need of more energy in the diet in winter than in summer.

The body's utilization of fat, F. S. MATHEWS (*Pop. Sci. Mo.*, 68 (1906), No. 5, pp. 425-430).—Modern views regarding the formation and utilization functions of fat, obesity and fat formation, etc., are summarized.

According to the author, "the question of the amount of fat in any individual is a very complex one, depending on such a variety of factors as condition of digestion, appetite, character and quantity of food, amount of exercise, and the proper working of a number of body glands."

The right method of eating and the evils of eating too rapidly or too slowly, M. EINHORN (*Ztschr. Diätet. u. Phys. Ther.*, vol. 8, p. 622; *abs. in Hyg. Rundschau*, 16 (1906), No. 9, pp. 501, 502).—The author believes that harmful results attend eating either too rapidly or too slowly. In the former case serious digestive disturbances may be induced, while the latter may cause mental depression which leads to chronic inanition.

Vegetable products in feces, F. NETOLITZKY (*Die Vegetabilien in den Fäces*, Vienna: Moritz Perles, 1906, pp. 100, figs. 39; *rev. in Ztschr. Untersuch. Nahr. u. Genussmitl.*, 11 (1906), No. 6, p. 376).—The identification in the feces of residues of vegetable origin by means of the microscope is described.

ANIMAL PRODUCTION.

The nutritive value of several kinds of hay, F. TANGL and S. WEISER (*Landw. Jahrb.*, 35 (1906), No. 1-2, pp. 159-223).—The digestibility and nutritive value of ordinary hay, hay from irrigated meadows and moors, Alpine hay, alfalfa hay, and sour hay were studied, the digestion experiments being made with horses, steers, and sheep.

Taking into account the energy value of the food, urine, feces, and the estimated energy value of the methane excreted, the authors calculated the physiological nutritive value—that is, the energy value of the food less the energy value of the excretory products.

The authors point out that the experiments furnish a demonstration of the belief that horses digest their food less thoroughly than ruminants, and that the smaller nutritive effect of the organic matter of hay in the case of horses is attributable to the greater loss in the feces—that is, to inferior digestibility. The results indicate that a botanical analysis of hay furnishes a satisfactory means of judging of its nutritive quality.

It was found that although cattle refuse hay made in the ordinary way from sedges and rushes, yet they will readily eat these plants when cured as sour hay—that is, allowed to ferment in pits. The nutritive value of this hay is, however, small at best.

The nutritive value of dried wine lees, S. WEISER (*Landw. Jahrb.*, 35 (1906), No. 1-2, pp. 224-238).—Digestion experiments with horses and steers showed that dried wine lees did not have a high nutritive value, in part at least owing to the stems and seeds present, which constituted 22 per cent of the whole. The urine was analyzed.

Composition and feeding value of cucurbits, A. ZAITSCHEK (*Landw. Jahrb.*, 35 (1906), No. 1-2, pp. 245-258).—Digestion experiments were made with steers and pigs to determine the digestibility and nutritive value of cucurbits of different sorts fed with hay.

The coefficients of digestibility with steers, calculated for pumpkins alone, were protein 70.3, fat 90.1, nitrogen-free extract 89.4, crude fiber 67.5, pentosans 68.7, and ash 72.6 per cent. The coefficients obtained in the tests with pigs were protein 72.3, fat 57.0, nitrogen-free extract 92.7, crude fiber 67.6, pentosans 70.1, and ash 61.9 per cent. The author believes that other sorts of cucurbits would have practically the same nutritive value.

The urine was analyzed and the amount of methan excreted was calculated. Taking these facts into account the physiological nutritive value of the cucurbits for steers was 70.2 and for pigs 69 per cent.

The nutritive value of ground beech bark, A. ZAITSCHEK (*Landw. Jahrb.*, 35 (1906), No. 1-2, pp. 239-244).—Digestion experiments were undertaken with sheep and pigs to ascertain the nutritive value of ground beech bark, a material offered as a feeding stuff in times of scarcity. The sheep could not be induced to eat the material even when mixed with molasses. The mixture was, however, eaten by swine, but the ground beech bark was found to be wholly indigestible. Analyses were made of the urine.

Report of progress regarding the proposed act to be introduced by the Dominion government relative to the sale of concentrated feeding stuffs, W. P. GAMBLE (*Ann. Rpt. Ontario Agr. and Expt. Union*, 25 (1905), pp. 59-61).—The need for a law requiring an inspection of concentrated feeding stuffs in the Dominion of Canada is spoken of and a report given of the efforts which have been made to secure the enactment of such legislation.

Fattening cattle for the years 1904 and 1905, F. B. LINFIELD (*Montana Sta. Bul.* 58, pp. 57-82).—(Continuing earlier work (E. S. R., 15, p. 709) 2 tests with steers are reported.

In the first test crushed wheat, ground oats, ground barley, and a mixture of equal parts of these grains were compared, the coarse fodder in every case consisting of clover hay. Each of the 4 lots contained 8 steers and the test as a whole covered 101 days. The average daily gain ranged from 2.06 lbs. per head on wheat to 2.35 lbs. on mixed grains. The greatest range in feed required per pound of gain and in the cost of feed per pound of gain was also noticed with these two lots, being respectively 1.83 and 2.15 lbs. and 4.56 and 5.33 cts. Considering this and earlier work the author estimates on the basis of the amounts required per pound of gain that the different grain rations supplemented by clover hay rank as follows: Mixed grain, barley, wheat, and oats.

In the second test different amounts of grain (barley, oats, and bran 2:1:1) were compared, the daily grain rations being respectively 3, 5, 7, and 10 lbs. per head. The coarse fodder in every case consisted of clover hay. Each of the 4 lots contained 6 steers and the feeding period covered 129 days. The smallest gain, 1.16 lbs. per head per day, was noted with the 5-lb. grain ration and the greatest gain, 1.37 lbs. per head per day, with the 10-lb. grain ration. The feed required per pound of gain ranged from 1.89 lbs. on the 3-lb. grain ration to 5.16 lbs. on the 10-lb. grain ration. The greatest variation in cost of feed per pound of gain, namely, 6.7 and 9.5 cts., was also noticed with these two lots.

“The results of the tests made during the winter 1902-3 and 1903-4 seemed to show that the relative value of the different grains (when fed with clover) to produce increase in live weight on a steer, is: 1st, mixed grain; 2d, barley; 3d, wheat; 4th, oats.

"In this test while the steers fed the larger grain ration gained more and faster than those fed the smaller grain ration, yet the gains were in no wise in proportion to the difference in the grain."

Feeding range steers, J. J. VERNON (*New Mexico Sta. Rpt. 1904, pp. 27, 28*).—The value for winter feeding of alfalfa hay alone and supplemented by a light grain ration of bran and cracked wheat 1:3 was tested with 2 uniform lots of 5 2-year-old range steers each. On alfalfa and grain the net profit was calculated to be \$7.42 per ton of hay and on the hay alone \$8.40.

The quantity of milk taken by nursing calves and its fat content, T. HENKEL and E. MÜHLBACH (*Landw. Vers. Stat., 63 (1906), No. 5-6, pp. 407-469, figs. 12*).—It was found in the experiments reported on methods to be followed with nursing calves that the best results were obtained when the calf nursed at frequent and regular intervals. If the calf nurses before the cow has been milked at all, it obtains milk of low fat content. If, however, the cow has been milked somewhat, the calf obtains milk rich in fat. The effect of different methods of milking and other related questions are also considered.

Sheep feeding experiments for the years 1904-5, F. B. LINFIELD (*Montana Sta. Bul. 59, pp. 85-116*).—In the first of the feeding tests the comparative value of wheat screenings, wheat, oats, barley, and a mixture of equal parts of wheat, oats, and barley, was tested with 5 lots of lambs and 5 lots of wethers, each lot containing 24 animals. The grain ration in every case was supplemented by clover hay.

During the whole period of the test, 97 days, the greatest gain of the wethers, 0.219 lb. per head per day, was noted with the lot fed wheat, and the smallest gain, 0.187 lb., with the lot fed the mixed grain. The cost of a pound of gain was lowest, 7.49 cts., on wheat screenings, and greatest, 8.73 cts., on mixed grain. With lambs the greatest gain, 0.256 lb., was noted on wheat screenings, and the smallest gain, 0.219 lb., on wheat. These two rations also showed the greatest range in cost, a pound of gain being valued at 3.8 cts. on screenings and 5.57 cts. on wheat. Considering all the lots, the average gain with wethers was 0.2 lb. and with lambs 0.237 lb., the cost of a pound of gain in the two cases being 7.92 cts. and 4.61 cts.

For feeding wethers, the author ranks the grains as follows when fed with clover hay: Wheat, barley, oats, wheat screenings, and mixed grains; and for lambs—screenings, oats, barley, mixed grains, and wheat.

When sold, some of the lambs which were light weight at the beginning of the test were not sufficiently finished to bring the highest price, and the author concludes that 3 months' time is not a sufficiently long feeding period for such animals.

In a test, covering 65 days, of clover hay and grain, with and without roots, which was made with 2 lots of 32 sheep each, the average gain per head per day with the roots was 0.205 lb. and without roots 0.195 lb., the cost of a pound of gain in the 2 cases being 6.4 and 7.3 cts. The sheep included in this test had been used in experiments on the effects of poisonous plants, and some of them had lost weight during the summer. On an average they weighed 83 lbs. each at the beginning of the trial. The roots fed in this and the following test consisted of sugar beets, with occasionally mangels.

Using one lot of 16 and one of 14 sheep, wheat screenings and mixed grain (barley, oats, and bran 2:1:1) were compared, the ration in each case containing clover hay and roots in addition to grain. In 65 days the average gain on screenings was 0.193 lb. and on grain 0.3 lb. and the cost of a pound of gain 6.2 and 4.4 cts. The feeding was then continued for 58 days, both lots being fed clover hay and roots with the mixed grain. During this period the average

gain was 0.213 lb. per head per day, and the cost of a pound of gain 5.7 cts. The sheep used in this test were badly "locoed" and when received were hardly strong enough to stand. They weighed on an average 42.5 lbs.

"'Locoed' sheep that had been treated with veruifuges fed during 123 days gained as rapidly and made as economic gains as a band of healthy wethers. Being small and thin, however, they would have to be fed at least twice as long to get them ready for the market."

Heavy (1.5 lb.) and light (1 lb.) grain rations were compared with 100 wethers divided into 2 uniform lots. The grain consisted of the mixture mentioned above and was supplemented by clover hay. On the heavier ration the average daily gain in the 65 days covered by the test was 0.208 lb. per head, and on the lighter ration 0.202 lb. per head, the cost of a pound of gain in the 2 cases being 6.5 and 7.3 cts. and the grain eaten per pound of gain 1.81 and 2.61 lbs. with 18.3 lbs. clover hay on an average.

Experiments with Suffolk and Lincoln crossbred sheep at Glen Innes Experimental Farm (*Agr. Gaz. N. S. Wales, 17 (1906), No. 3, pp. 236-238, fig. 1*).—The breeding tests were carried on by R. H. Gemys, who found that the Lincoln-Merino cross produced heavier wool than the Suffolk-Merino. The wool of all the crosses was much improved by the Merino blood. As mutton sheep the Suffolk-Merino crosses, both as lambs and as full-grown sheep, were superior to the others. Sufficient data have not yet been accumulated regarding the Romney and Shropshire crosses for drawing deductions.

Effect of covering the body on the distribution of fat, J. BERGONIE (*Compt. Rend. Soc. Biol. [Paris], 60 (1906), No. 16, pp. 791, 792*).—Experiments with lambs with one-half the body shorn at intervals of 8 days failed to show any effect upon the formation of fat. Slight differences in the distribution of the fat on the shorn and unshorn sides were noted.

Pig feeding experiments, F. B. LINFIELD (*Montana Sta. Bul. 57, pp. 39-56*).—In the first of the tests reported the relative efficiency of grain and alfalfa hay and grain and roots with and without exercise was studied with 4 lots of 4 pigs each, the test covering 80 days. The roots fed in this and other tests were nearly always sugar beets. The average daily gain per pig on grain and hay with exercise was 0.57 lb. and without exercise 0.42 lb., and on grain and roots with exercise 0.65 lb. and without exercise 0.30 lb.

In the second test barley and bran alone and supplemented by skim milk and by clover hay were compared with 3 lots of 5 pigs each for 98 days.

The third test was like the second except that sugar beets as a supplement to barley and bran were also included. This test covered 81 days and the 4 lots contained 4 pigs each. Considering both tests the average gain on grain alone was 0.92 lb., on grain and skim milk 1.37 lbs., and on grain and clover hay 1 lb. per head per day. The corresponding gain on sugar beets was 1.09 lbs.

In the third test the lots fed barley and bran and grain and clover hay were not ready for market at the close of the test, so the feeding was continued for 17 days, the ration consisting of the grain mixture supplemented by roots and skim milk. The average daily gain per head was 1.8 lbs.

In the fourth test reported full rations of grain wet up with water and with skim milk were compared with a one-fourth grain ration mixed with water, the rations in every case being supplemented by pasturage. Two of the lots contained 3 pigs each and the remaining lot 2 pigs. The test covered 55 days. On the full grain ration mixed with water the gain was 1.41 lbs. per head per day, on the full grain ration with skim milk 1.70 lbs., and on the half grain ration 0.94 lb.

Omitting the first test and the supplementary period of the third test the author calculates that on grain alone 5.28 lbs. were required for a pound of gain and smaller amounts when other feeds supplemented the grain.

The author calculates that in none of the tests did the pigs return the market price for the feed if valued at 4 cts. per pound live weight. If sold at 6 cts. per pound the calculated gain would average \$1.85 per 100 lbs. feed.

"A point of considerable importance is that this result indicates that when running on pasture, hogs will keep in good condition and even gain in live weight on a light grain ration. There are yet many other facts, however, to be worked out along the lines of this test.

"The important point brought out in this test is the value of some supplementary food added to the grain ration in fattening hogs. . . .

"In these tests, skim milk, sugar beets, clover, or alfalfa have been used, and their value seems to be in the order named. It is apparent that in some way these additional foods have a value beyond what their composition would indicate. These supplementary foods seem to act in two or three ways. 1st, they seem to stimulate the appetites of the animals so that they eat more of the grain and make more economic gains because there is a larger surplus over the requirements of the body to turn into meat. 2d, these supplementary foods may aid the digestion of the hogs so that they can make better use of the food given them."

Digester tankage for swine, R. S. SHAW (*Michigan Sta. Bul.* 237, pp. 149-157).—So much milk is supplied to cheese factories, condensed-milk factories, and sold to cities and towns that on many farms there is a scarcity of skim milk for feeding young calves and pigs. A substitute for skim milk is, therefore, desirable and the value of digester tankage for this purpose was studied for young pigs in 1 test of 56 and 2 tests of 70 days' duration with pigs 50 to 120 days old at the beginning of the trial.

In one of the tests corn meal, middlings, and tankage 3:3:1 mixed with water were compared with the same grain ration mixed with skim milk. In the other tests middlings and corn meal 2:1 with the addition of one-eleventh of tankage wet up with water were compared with the same grain ration mixed with skim milk in the proportion of 1 lb. of meal to 3 lbs. of milk.

On the tankage rations the average daily gain was 0.98 lb. and the feed consumed per pound of gain 3.14 lbs. On the meal and skim milk rations the average daily gain was 1.08 lbs. per head and the feed required per pound of gain 2.48 lbs. meal and 5.67 lbs. skim milk. In a check test covering 10 weeks in which 2 lots of 5 pigs each were fed middlings and corn meal 2:1 mixed to a thick slop with water 4.09 lbs. of meal were required per pound of gain, the average daily gain being 0.8 lb.

"The indications . . . are that digester tankage can be used successfully as a substitute for skim milk in the ration for the growing pig from weaning time on." The results suggest "that a slightly greater proportion of tankage than one-eleventh of the ration could be fed, increasing the gains somewhat, and still keeping within the cost of production of the skim milk ration."

Corn meal and digester tankage in the proportion of 5:1 and 9:1 were compared for fattening pigs with rations of corn meal only and with rations of middlings and corn meal 2:1 with and without the addition of one-eleventh of tankage. The tests covered from 70 to 98 days. The average daily gain per pig on the tankage rations was 1.19 lbs. and on the rations without tankage 0.98 lb. The average cost of a pound of gain with tankage was 4.44 cts. and without tankage 4.86 cts.

"The gains were greatest in every case where tankage was used in the ration and this was more and more noticeable as the feeding period was prolonged. . . .

In general the figures given indicate that tankage can be used to good advantage in the ration for the fattening hog as well as for the growing pig."

Motion and muscular work in relation to digestion in horses, A. SCHEUNERT (*Landw. Jahrb.*, 34 (1905), No. 5, pp. 805-827).—Practical deductions are drawn from experiments previously reported (E. S. R., 17, p. 585). If work is reasonable in amount and not continued until great fatigue is induced it does not exercise any unfavorable effect upon the digestion in horses, but, on the other hand, may exercise a favorable effect. Animals which have worked before they are fed and are allowed to rest after eating digest their food in the same way as horses at rest.

The Ranidæ: How to breed, feed, and raise the edible frog (*Allendale, N. J.: Meador Brook Farm, 1905*, pp. 31, figs. 9).—The author believes that frog raising for market may be made a profitable industry and some directions are given which, it is claimed, are based on experience. The life history of the frog is described.

The author states that the common frogs of America are *Rana esculenta* and *R. temporaria* and recommends the former as the species which should be raised for market. In his statements he has apparently confused the English and American species as it is *R. catesbeiana*, a large frog, which is commonly eaten in the United States, whereas the small English frog (*R. esculenta*) is not indigenous here.

Studies in oyster propagation, J. NELSON (*New Jersey Stat. Rpt. 1905*, pp. 400-421, pls. 14).—Cloth and felt covered boxes were devised in which fertilized oyster spawn was placed together with suitable material to which the young oysters could attach themselves. These boxes were placed in a number of localities to study the conditions under which oyster spat forms, the experiment as a whole being a continuation of earlier work on oyster propagation (E. S. R., 17, p. 393). The results obtained were for the most part negative.

"It seems evident that spawn artificially prepared lacks something to enable it to grow into spat, or possibly there was an element lacking in the boxes. These points must be investigated next season."

In general, the boxes were regarded as satisfactory. The water inside seemed to be pure and as rich in oyster food as that outside. The fixation of oyster spat and the genesis of oyster spawn are illustrated by a number of plates.

First lessons in poultry keeping, J. H. ROBINSON (*Boston: Farm Poultry Pub. Co., 1905*, pp. 168, figs. 61).—In a series of lessons designed for home instruction, breeding, feeding, care of poultry, the use and management of incubators, the construction and furnishing of poultry houses, and related questions are taken up.

Poultry work for 1905, J. H. SHEPPERD (*North Dakota Sta. Rpt. 1905*, pp. 46-48).—A brief summary of data on the eggs laid, set, and hatched; the poultry used and sold; and the finances of the station poultry department.

The American standard of perfection (*Amer. Poultry Assoc., 1906*, pp. 299, figs. 124).—As stated in the subtitle, this volume contains a description of all varieties of fowls, including domestic poultry, ducks, turkeys, and geese, recognized by the American Poultry Association and is designed as a manual for judging poultry. This edition was prepared at the twenty-eighth annual meeting of the American Poultry Association at Rochester. The material published in earlier editions has been revised and new breeds and varieties have been added, "but the policy has been, and is, to admit only such as have become well established and that clearly are entitled to the distinctive term 'standard-bred.'" The volume also contains a glossary of technical terms and the constitution and by-laws of the American Poultry Association.

The production of brown or tinted eggs (*Jour. Bd. Agr. [London], 12 (1906), No. 10, pp. 611-613*).—Since brown-shelled eggs are preferred in the British market and bring a higher price their production is discussed. Langshans, Cochins, Plymouth Rocks, Orpingtons, Game, Wyandottes, Brahmas, Faverolles, and Coucons de Malines produce eggs of the desired color. A number of satisfactory crosses are also suggested. "In crossing two breeds producing respectively white and tinted eggs, it is necessary to depend chiefly upon the females for conservation of the tinted characteristic, and it is advisable that in such crossing the male only should be selected from the white egg-producing races."

Egg production of virgin fowls, J. NELSON (*New Jersey Stas. Rpt. 1905, pp. 393-400*).—The presence of the male bird on egg production was studied, but the results obtained up to the present time are not regarded as sufficient for general deductions. In general, more broody hens were noted in the lot having the male bird, but the differences were not very great.

DAIRY FARMING—DAIRYING.

Feeding experiments, G. A. BILLINGS (*New Jersey Stas. Rpt. 1905, pp. 336-349*).—The feeding experiments reported in 2 recent bulletins of the station (*E. S. R., 17, p. 900*) are summarized and an account is given of a comparative test of 2 grain rations, one consisting of 5 lbs. of dried distillers' grains and 5 lbs. of wheat bran, and the other of 4.5 lbs. of dried brewers' grains, 4.5 lbs. of wheat bran, and 1 lb. of cotton-seed meal. The test was made with 4 cows and lasted 30 days. The first ration mentioned, as compared with the second, increased the average daily yield of milk 5 lbs. per cow and the fat content 0.07 per cent and decreased the cost of production 11.4 cts. per 100 lbs. of milk and 1.32 cts. per pound of butter.

Experiments with the dairy herd, G. A. BILLINGS (*New Jersey Stas. Rpt. 1905, pp. 376-390, pls. 6*).—The improvement of dairy herds is briefly discussed and an experiment in breeding a pure-bred Guernsey sire upon common stock is reported. The records of 1 dam and 4 heifers are given. In every instance the fat content of the milk of the offspring was higher than that of the mother. This practice is recommended not only for increasing the fat content of the milk but for giving the milk a higher color.

Notes are given on the construction of concrete mangers for cattle and on improvements in the milk room at the station, including the laying of a concrete floor.

The value of keeping milk records is illustrated by the records of the college herd. The data obtained during 9 years on the cost of producing and handling milk indicate that cows producing yearly less than 5,000 lbs. of milk containing 4 per cent of fat are unprofitable. With milk at 3 cts. per quart the records show that 30 cows have returned profit over and above the value of manure, while 11 were unprofitable. With butter at 20 cts. per pound only 13 out of 44 cows showed any profit above the manure after deducting for feed, labor, interest on the capital invested, and depreciation of the herd.

Dairying, J. J. VERNON (*New Mexico Sta. Rpt. 1904, pp. 28, 29*).—In experiments with 8 cows, feeding bran with alfalfa hay was compared with feeding alfalfa hay alone. In 12 weeks 4 cows consumed 11,207 lbs. of alfalfa hay and 2,700 lbs. of bran and produced 5,543 lbs. of milk, while 4 cows fed alfalfa alone consumed 11,378 lbs. of hay and produced 4,628 lbs. of milk.

Tests of Guernsey cows for advanced registry (*Connecticut State Sta. Rpt. 1905, pt. 6, p. 343*).—Nine cows were tested during the year, the records of 3 being given.

Milking trials (*Jour. Brit. Dairy Farmers' Assoc.*, 29 (1906), pp. 135-169).—Two-day tests of 73 cows and 8 goats are reported in detail. Summaries of previous tests have been noted in E. S. R., 16, pp. 594 and 1118. The average yield of milk in pounds and the contents of fat and solids-not-fat in percentages for the tests in 1905 by breeds are respectively as follows: Shorthorn, 49.1, 3.85, and 8.99; Jerseys, 31.7, 5.25, and 9.14; Guernseys, 31.4, 4.81, and 9.15; Red Polls, 38.5, 3.63, and 8.93; Kerries, 28.2, 4.10, and 8.96; and crosses, 45.7, 3.82, and 9.08.

An experimental inquiry into the factors which determine the growth and activity of the mammary glands, J. E. LANE-CLAYTON and E. H. STARLING (*Proc. Roy. Soc. [London]*, Ser. B, 77 (1906), No. B 520, pp. 505-522, pl. 1).—The experiments consisted in injecting fluid extracts of the ovary, uterus, placenta, and fetus into virgin rabbits with a view to producing changes in the mammary glands which occur normally in pregnancy. In 6 cases the authors produced in this way a branching in the ducts of the mammary glands, a proliferation of the epithelial cells, and in one instance a formation of secreting acini. While the results were not considered entirely conclusive they favor the view advanced by Hildebrandt that the growth of the mammary gland during pregnancy is due to the action of a specific chemical stimulus produced largely in the fetus, which inhibits the secretory activity of the gland cells. Lactation is, therefore, due to the removal of this substance.

The elimination of nitrates by the mammary gland, L. MARCAS and C. HUYGE (*Bul. Agr. [Brussels]*, 22 (1906), No. 2, pp. 217-225).—The dependence placed upon the presence of nitrates in milk as a proof of watering, led the authors to administer potassium nitrate to 22 cows and test their milk by diphenylamin. Nitrates were irregularly detected in the milk.

On the bacteriological conditions of the udder and the milk, C. BARTHEL (*K. Landtbr. Akad. Handl. och Tidskr.*, 45 (1906), No. 1, pp. 48-56).—The author corroborates Ward's and von Freudenreich's conclusions that bacteria normally find their way into the udder of the cow, and shows that these are mostly cocci, while typical milk bacteria are not able to invade the udder. The article gives a review of the results of investigations conducted along this line by Conn and Stocking, Kelle, Sommerfeld, and others.—F. W. WOLL.

Bitter milk, C. HUYGE (*Bul. Agr. [Brussels]*, 22 (1906), No. 2, pp. 213-216). This gives the cultural characteristics of a bacillus isolated from bitter milk. The organism was destroyed in whole milk by sterilizing at 105° for 5 minutes and in cream by heating at 90° for 5 minutes on 3 successive days. The thorough application of this method caused the disappearance of this trouble from the dairy under investigation.

Spontaneous heat production in cows' milk and lactic acid fermentation, M. RUEBNER (*Arch. Hyg.*, 57 (1906), No. 3, pp. 244-268, figs. 10).—The author investigated the amount and sources of the heat produced during the spontaneous souring of milk. Numerous determinations showed that less than one-half of the heat produced during the lactic fermentation was due to the decomposition of the milk sugar and accordingly that the proteins or fat must also be concerned in the heat production.

The action of formalin and hydrogen peroxid in milk, P. BANDINI (*Centbl. Bakt. [etc.]*, 1. Abt., Orig., 41 (1906), Nos. 2, pp. 271-279; 3, pp. 379-386; 4, pp. 474-480).—The author studied the action of rennet in milk treated with different quantities of formaldehyde and hydrogen peroxid, the effect of these preservatives upon the soluble ferments of milk, the action of artificial ferments in milk preserved with these substances, and the amounts of formaldehyde and hydrogen peroxid required to preserve milk for practical purposes.

The results of the experiments showed that formaldehyde tends to prevent the curdling of milk with rennet, the extent of this influence being greater the longer the preservative is in the milk and the larger the amount used. On the other hand, rennet acted the same in the case of milk preserved with hydrogen peroxid as upon normal milk. Neither preservative exerted an appreciable influence upon the soluble ferments normally present in milk. Unlike hydrogen peroxid, formaldehyde even in small quantities retarded the proteolytic action of rennet and pancreatin and when used in large amounts produced marked changes in the physical and chemical properties of the casein. In the proportion of 1:5,000 to 1:10,000 formaldehyde preserved milk from 6 to 12 days. The author considers it highly probable that the continued use of milk so preserved would be injurious. Hydrogen peroxid in amounts of 1 to 3 per cent preserved milk 3 to 6 days and such milk is believed to be in no way injurious. A bibliography is appended.

On the addition of foreign fats to milk, C. GIRARD (*Abs. in Chem. Ztg.*, 30 (1906), No. 41, p. 504).—The author's experiments were made with cocoanut oil, lard, cotton-seed oil, margarin, etc., and showed that the addition of these materials to milk required special apparatus and the employment of a temperature of 80° C., which gave the mixture a taste rendering it unpalatable.

Grading cream, O. ERF (*Kansas Sta. Bul.* 135, pp. 133-144).—In the dairy department of the college cream has been graded for nearly 2 years with, it is stated, universal satisfaction to the patrons and a marked improvement in the quality of the cream. According to the scheme used, cream to be of first grade should contain not more than 0.2 per cent of acid, have no undesirable flavors or odors, be not over 3 days old, and contain not less than 30 per cent of fat. Second-grade cream may contain as much as 0.3 per cent of acid but should be untainted, not more than 5 days old, and should contain 30 per cent or more of fat. Third-grade cream may be somewhat stale and tainted and contain less than 30 per cent of fat. It is estimated that there should be a difference in price of at least 4 cts. between the first and second grades and not less than 2 cts. between the second and third.

The bulletin also discusses the grading of butter, gives directions for the determination of the acidity of cream, enumerates the causes of undesirable flavors and odors in cream, and makes suggestions concerning the proper care and handling of cream.

A new Babcock milk-testing bottle, R. C. WHITMAN (*Jour. Amer. Med. Assoc.*, 47 (1906), No. 3, pp. 204, 205).—The bottle described has been designed for testing small quantities (5 cc.) of milk and for use in an ordinary urine centrifuge. Into the neck of the bottle proper is ground a graduated glass tube, making both not to exceed 5½ in. in length. It is stated that the bottles have been compared repeatedly with the regulation Babcock bottles and have given identical results.

Examination of Babcock test apparatus (*Connecticut State Sta. Rpt.* 1905, pt. 6, p. 343).—During 1905, 4 pipettes, 216 cream-test bottles, and 73 milk-test bottles were tested. All were found accurate except 4 milk-test bottles.

Investigations in the manufacture and storage of butter. I, The keeping qualities of butter made under different conditions and stored at different temperatures, C. E. GRAY: with remarks on the scoring of the butter, G. L. MCKAY (*U. S. Dept. Agr., Bur. Anim. Indus. Bul.* 84, pp. 24).—This bulletin, which is the first of a contemplated series, gives results of one season's work in making butter under different conditions and storing it under different temperatures. The plan embraced a study of the keeping qualities of butter as affected by (1) temperature of storing, (2) pasteurization of cream, (3) salting,

(4) packing in tubs and cans, and (5) filling cans partly and entirely full. The results are summarized by Mr. Gray as follows:

"Butter containing low percentages of salt kept better than did butter of the same lot containing higher percentages of salt.

"Butter in full cans and tubs at -10° and $+10^{\circ}$ F. scored about the same. At $+32^{\circ}$ F. there was a slight difference in favor of cans.

"Butter in full cans kept much better than did butter in cans only partially full, the deterioration doubtless being due to the presence of air in the partially full cans.

"Butter held at -10° F. kept best, both when in storage and after removal from storage.

"Butter made from cream received at the creamery sweet and in good condition kept well while stored at -10° and $+10^{\circ}$ F.; also after removal from storage, giving results wholly satisfactory.

"Butter made from cream received at the creamery sour and in fair condition kept well while in storage at -10° and $+10^{\circ}$ F., but deteriorated rapidly after removal from storage, giving, on the whole, results which were very unsatisfactory."

Professor McKay, who was one of the judges, comments upon the scoring of the butter, concluding from all the data at hand that in these experiments light salting and low temperatures gave much the best results for storage butter.

Yields of salted and unsalted butter, F. FRIS (*Abs. in Mækeritid., 19 (1906), No. 19, pp. 130-133*).—Trials were conducted in two different creameries to determine the yields of butter from ordinary ripened cream, with and without salting. The butter was worked three times, the second time 1 to $1\frac{1}{2}$ hours after the first working, and the third time 3 to 4 hours after the second. Both the cream and the buttermilk contained about the same amounts of butter fat in each trial. For each 100 lbs. of salted butter an average of 98.5 lbs. of unsalted butter was obtained, the increase in the yield of salted butter being caused by the 3.5 per cent of salt added, which more than made up for the greater loss through working out of water. The average water content of the salted butter was 14.42 per cent and of the unsalted 15.31 per cent. The solids-not-fat in the salted butter averaged 3.27 per cent and in the unsalted 1.17 per cent.—F. W. WOLL.

Denmark's butter exports, 1904-5, B. BÖGGILD (*Tidsskr. Landökonom., 1905, No. 12, pp. 630-644*).—The article contains the usual summary of butter imports and exports from Denmark during the year ending September 30, 1905. The imports amounted to about 39,000,000 Danish pounds, and the exports to 190,000,000 pounds. The net exports, therefore, amounted to 151,000,000 pounds, 1,000,000 pounds less than the preceding year.—F. W. WOLL.

The cold storage of cheese, C. B. LANE (*U. S. Dept. Agr., Bur. Anim. Indus., Bul. 83, pp. 26, pls. 6, figs. 4*).—The author, aided by D. Stuart, has brought together the results of experiments carried out by the late Maj. H. E. Alvord, during 1903-4, to determine the influence of different temperatures of storing upon the weight and quality of paraffined and unparaffined cheese. The temperatures compared were 28° , 34° , and 40° F. Paraffined and unparaffined lots of the 3 types of cheese known commercially as Cheddars, Flats, and Young Americas, weighing on an average 68, 37.7, and 10.4 lbs., respectively, and aggregating about 3 tons, were stored at these temperatures, and in addition a test on a much smaller scale was made of the effect of storing cheese at a temperature of about 5° .

During 247 days the unparaffined Cheddars stored at 40° lost 5.87 per cent in weight, at 34° , 5.12 per cent, and at 28° , 2.88 per cent. During the same period the Flats lost at 40° , 5.53 per cent; at 34° , 4.37 per cent, and at 28° , 2.19

per cent. During 233 days the Young Americans lost at 40°, 9.34 per cent; at 34°, 6.95 per cent, and at 28°, 4.25 per cent. Assuming that the cheese sold at a uniform price of 10 cents a pound, the profits in storing at 28° over 40° were 30 cents per hundred for Cheddars, 33 cents for Flats, and 51 cents for Young Americans.

Paraffining reduced the loss in weight of the Cheddars to 3.19 per cent at 40°, 1.36 per cent at 34°, and 1.27 per cent at 28°, and the loss in weight of the Young Americas to 2.38 per cent at 40°, 2.11 per cent at 34°, and 1.45 per cent at 28°. Comparing paraffined cheese at 28° with unparaffined cheese at 40°, the saving from paraffining amounted to 46 cents per hundred for Cheddars and Flats and 52 cents for Young Americas.

The quality of the cheese was not influenced to any marked degree by the different temperatures used and was not injured in any instance by paraffining.

Investigations in the manufacture and curing of cheese. VI. The cold curing of American cheese, with a digest of previous work on the subject, C. F. DOANE (U. S. Dept. Agr., Bur. Anim. Indus. Bul. 85, pp. 68).—After reviewing previous experiments in cold and cool curing of cheese in the United States and Canada, the author reports an experiment made at Plymouth, Wis., for the purpose of determining the effect of different low temperatures of storage and the time of putting into storage upon the curing of the cheese. The cheese used was manufactured under strictly commercial conditions, placed in storage directly from the press and at the age of one and two weeks, and held at temperatures of 32° and 40° F. Rennet was used for part of the cheese at the rate of 3 oz. per 1,000 lbs. of milk, and for the remainder at double this rate. All the cheese was paraffined. The details of manufacture, the weights of cheese at different periods, and the numerical and descriptive scores are presented in tabular form and discussed.

Paraffining and placing in storage at the end of one week lessened considerably the loss in weight, as compared with paraffining and storing at the end of two weeks. This was considered the most interesting feature of the results so far as loss in weight was concerned. In many cases there was no shrinkage whatever from the time of paraffining to the time of final weighing, 5 to 7 months later.

The average total scores for low rennet cheese were as follows: Placed in storage directly from the press and held at 32°, 95, and at 40°, 94.3; placed in storage at the end of 1 week and held at 32°, 93.8, and at 40°, 90; placed in storage at the end of 2 weeks and held at 32°, 93, and at 40°, 90, and cured at the factory 81.4. The scores for the high rennet cheese were as follows: Stored from the press at 32°, 94.4, and at 40°, 92.3; stored at the end of 1 week at 32°, 93.4, and at 40°, 90.3; stored at the end of 2 weeks at 32°, 91.6, and at 40°, 90.9, and cured at the factory, 90.5.

In some instances taints developed in cheese kept out of cold storage for 1 and 2 weeks, but did not appear in the cheese placed in storage directly from the press. Furthermore, when the taints had once started to develop, the 32° temperature served much better to hold them in check than the 40° temperature. The author therefore believes that the greatest beneficial influence of cold curing is with what would otherwise be poor cheese. Contrary to the belief generally held by dealers, the results indicate that cheese with too much acid should be placed in cold storage as quickly as possible and the colder the room the better.

The high rennet cheese ripened more rapidly than the low rennet cheese, and held its good qualities fully as long if not longer.

The manufacture of Lancashire cheese, F. J. LLOYD (Jour. Brit. Dairy

Farmers' Assoc., 20 (1906), pp. 36-52).—The author has investigated the methods of making cheese in Lancashire and in this article makes suggestions for overcoming faults and difficulties observed by him, and reports some experimental work. Determinations were made of the acidity during different stages in the process of manufacture. It was found that those cheeses which contain from 0.95 to 1 per cent of acid in the liquid from the press were on the whole best. Previous investigations with Cheddar cheese showed that for a slow ripening cheese an average acidity of about 0.85 per cent in the liquid from the press is required, for a quick ripening cheese an acidity of 1 per cent, and for a very quick ripening cheese about 1.15 per cent. The same standards are found to hold good for Lancashire cheese. Bacteriological studies showed that the flora of this cheese is quite different from that of other varieties.

The distribution of lactic-acid bacteria in curd and cheese of the Cheddar type, F. C. HARRISON (*Rev. Gén. Lait*, 5 (1906), No. 18, pp. 309-315, pls. 4).—The author has made use of the histological methods employed by Petersson, Gorini, and Rodella (*E. S. R.*, 17, p. 400). The best results were secured by embedding the curd or cheese in paraffin with bergamot oil and staining the sections on cover glasses with Gram's method and counterstaining with eosin. By this method lactic-acid bacteria, yeasts, and torulae were well demonstrated. Bacteria of the colon type which decolorize by Gram's method were brought out by counterstaining with Bismarck brown. By decolorizing and dehydrating in amyl alcohol, practically all the bacteria were stained.

The lactic-acid bacteria were found to increase very rapidly in numbers from the time of adding the rennet until the time of salting, but only slightly from the time of salting until the cheese was 1 or 2 days old. Comparison, however, was rendered difficult by the large numbers present. They showed a tendency to form clumps or colonies, in some of which over 1,000 were counted. The results by this method are considered as confirming quantitative analysis by the plate method.

Composition of the principal types of cheese consumed in France, LINDET, AMMANN, and BRUGÈRE (*Rev. Gén. Lait*, 5 (1906), No. 18, pp. 416-418).—Analyses of 24 types of cheese by the same methods and under identical conditions are reported.

Investigations on the ripening of cheese, G. CORNALBA (*Ann. Soc. Chim. Milano*, 12 (1906), No. 1-2; *abs. in Rev. Gén. Lait*, 5 (1906), No. 18, p. 419).—In Grana and other types of cheese investigated, ripening was found to progress centrifugally, the quantity of soluble casein in the ripened cheese was limited and the formation of ammonia from the soluble casein was considerable. Butyric acid predominated in the Grana cheese, though caproic, acetic, and higher acids were present. The fat did not undergo any change, the volatile fatty acids not being saponified by the ammonia.

A handbook for test associations, N. HANSSON (*Kontrollföreningarnes arbetsfält. Matuö; E. Jansson, 1905, pp. 125, figs. 12*).—This contains a sketch of Swedish dairy test associations, with directions for feeding and milking cows, weighing and testing milk, and keeping records. In September, 1905, there were 326 different associations in Sweden. The membership of 298 associations for which complete statistics are given was 3,447. The total number of cows owned by members of the association was 12,701.—F. W. WOLL.

A handbook for members of test associations, R. GRIPENBERG (*Kort Handledning i Utödringskontroll. Helsingfors; Gort., 1905, pp. 25*).—This contains brief directions for the control of the feeding and production of cows in test associations with schedules and blanks to be used.—F. W. WOLL.

Profitable dairy farming, N. HANSSON (*En lönande lögårdsskötsel*.

Malmö: E. Janssons, 1905, 2. ed., pp. 136, figs. 31).—A popular illustrated treatise on dairy husbandry, including the breeding and feeding of the dairy herd.—
F. W. WOLL.

VETERINARY MEDICINE.

Annual report on progress with pathogenic micro-organisms, including bacteria, fungi, and protozoa, P. VON BAUMGARTEN and F. TANGL (*Jahresber. Path. Mikroorgan., 19 (1903), pp. XII+1220*).—An elaborate review is presented of the literature on pathogenic micro-organisms which appeared in 1903. The editors were assisted by a large corps of specialists who divided up the work according to their particular qualifications. The review of literature includes text-books and original articles or treatises on all forms of pathogenic cocci, bacilli, and other forms of bacteria and fungi, including actinomyces, protozoa of all groups which furnish pathogenic forms, as well as works on general microbiology, disinfection, and biological technique. Bibliographies are furnished in connection with each section, and the volume is also supplied with complete author and subject indexes.

Collected studies on immunity, P. EHRLICH, trans. by C. BOLDUAN (*New York: John Wiley & Sons; London: Chapman & Hall, Ltd., 1906, pp. XI+586, pl. 1*).—Since the publication of the German edition of this collection, two additional chapters have been prepared by Ehrlich and Sachs, which are also included in the present English edition, and a general review of recent work in immunity was prepared by Ehrlich expressly for the translation. The subject of immunity in so far as the writings of Ehrlich and his disciples are concerned is therefore brought down to date. The original German edition has already been noted (*E. S. R., 16, p. 96*).

The local treatment of parasitic and infectious diseases with remedies introduced in connection with an electric current, D. BERNARDINI (*Clin. Vet. [Milan], 29 (1906), No. 20, pp. 490-494*).—From time to time experiments have been made to determine the influence of an electric current in hastening and intensifying the penetration of drugs applied locally. The author secured some rather positive results from the use of this method. Rabbits were inoculated with anthrax cultures in the tissue of the ear and after 3 hours a solution of corrosive sublimate was applied to the point of inoculation under the influence of an electric anode for a period of 10 minutes. Another rabbit was treated in the same manner except that the application of an electric current was omitted. After 56 hours it appeared that the rabbit which was not treated with electricity exhibited all of the bacteriological and pathological symptoms of anthrax while the other animal remained entirely normal.

Public abattoirs. I, Construction and arrangement, J. DE LOVERDO (*Abattoirs publics. I, Construction et agencement. Paris: H. Dunod & E. Pinat, 1906, pp. VIII + 902, pls. 11, figs. 375*).—This volume contains an elaborate account of the construction of abattoirs in France and other countries, particular attention being given to those in France with historical notes on the development of abattoirs in that country. The author discusses in a detailed manner the various points of construction, arrangement of rooms, and apparatus and other matters related to the architecture, sanitary regulation, ventilation, and use of abattoirs. Particular attention is given to cold storage plants and their proper regulation in connection with abattoirs as well as to various other secondary industries dependent upon abattoirs.

Public abattoirs. II, Inspection and administration of abattoirs and cattle markets, H. MARTEL, J. DE LOVERDO, and MALLET (*Abattoirs publics,*

H. Inspection et administration des abattoirs installation des marchés aux bestiaux. Paris: H. Dunod & E. Pinal, 1906, pp. VI + 675, pls. 8, figs. 110).—This volume completes the general account of abattoirs and contains a detailed discussion of the administration and inspection work to be carried on in abattoirs and small slaughterhouses. The subject-matter is arranged under a number of different heads, including sanitary inspection of animals, the reasons for inspection, the obligations of meat inspectors, condemnation of meat, French legislation, methods of inspection of various animals, stations for inspecting imported meat, inspection of private abattoirs, special inspection of meat for use by the army, the use of horses and dogs for food, inspection of animals before slaughter by veterinary police, meat legislation in countries other than France, inspection of abattoirs and connected buildings for sanitary conditions, general administration of abattoirs and cattle markets, and insurance against condemnation.

Report of the veterinarian, G. H. GLOVER (*Colorado Sta. Rpt. 1905*, pp. 51-61).—The work of the veterinarian has been largely confined to investigations relating to poisonous plants. In this work attention was given to a number of plants. Two pastures were arranged, one being free from loco and the other containing large quantities of both white and purple loco. Six steers and 7 horses were placed in each of these pastures in order to determine the effect of eating loco. The animals maintained in the pasture free from loco kept in good condition during the season, while those on the loco pasture were badly affected and finally all of them died. The injurious effects of eating loco were manifested within a week, the symptoms being those of general prostration and malnutrition. If such animals were removed from the loco pasture they soon recovered, but were again affected when replaced in the loco pasture. It appeared during the experiments that white loco was preferred and that the most positive results may be obtained with cattle. Post-mortem examinations failed to reveal any lesions. It was concluded from this work that the loco disease is a specific condition associated with at least one species of plant (*Astragalus mollissimus*). Horses and cattle prefer grass to the loco plant, which seems to have a low nutritive value. Animal parasites are not found in larger quantities in locoed animals than in other animals.

It is estimated that the annual losses from larkspur in Colorado are about \$40,000. Five species have been found to be poisonous—*Delphinium bicolor*, *D. glaucum*, *D. scopularium*, *D. azureum*, and *D. penardi*. Larkspur appears to lose its toxic properties as it approaches the flowering period. The best results in treating poisoned animals were obtained from the use of potassium permanganate and atropin. Notes are given on a number of other harmful plants, including a species of rubber plant (*Actinella richardsonii*), water hemlock, death camas, etc.

Eradication of tuberculosis by the methods of Bang and Ostertag with reference to the applicability of these methods to Saxony, J. RICHTER (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 1 (1906), No. 2-3, pp. 187-210).—Tuberculin tests show that in Saxony about two-thirds of the cattle in the whole kingdom are affected with tuberculosis. The unusual prevalence of this disease makes it necessary to devise a practical method of not too great expense in controlling the disease. As is well known, Bang's method consists in the inoculation of each herd with tuberculin, the separation of healthy and reacting animals into two herds, which must be kept separate thereafter and under the care of different attendants, the rearing of calves on cooked milk, the disinfection of the stables in which the healthy part of the herd is kept, and a repetition of the tuberculin test every 6 months. This method, while effective, has been

found altogether too expensive and too elaborate for application to the average farm. For this reason it is utilized less and less even in Denmark, where government aid is secured in carrying it out. The chief objection to Bang's method is the great increase in the amount of labor necessary to maintain two separate herds on different parts of the farm and prevent infection from spreading from one to the other. Moreover, the repetition of the tuberculin test at frequent intervals has been found to be a considerable hardship. The author believes that Bang's method is practical in localities where only a few herds are affected or in herds where the number of tuberculous animals is not great. In Saxony, however, with two-thirds of the cattle tuberculous, the method is considered quite unpractical.

Ostertag's system of eradication consists simply in the destruction of cattle affected with tuberculosis to such an extent that it may be readily recognized by physical symptoms and the rearing of calves under conditions which prevent infection. This method does not require the separation of the herd into tuberculous and healthy groups, but merely requires, as soon as the disease becomes advanced far enough so that the animals may spread it by coughing or otherwise, that such animals be destroyed. The calves are reared on pasteurized or sterilized milk or on the milk of other healthy cows. While Ostertag's method may not seem to satisfy sanitary requirements so strictly as that of Bang, it is much less expensive, more easily put in operation by the average farmer, and, as experience has shown, almost if not equally effective. The author believes that Ostertag's method is not capable of eradicating tuberculosis, at least within a short time, in a herd without separation of diseased animals, but that it does prevent a further infection and that the method is particularly applicable to the conditions in Saxony.

Experiments with milk artificially infected with tubercle bacilli, E. C. SCHROEDER and W. E. COTTON (*U. S. Dept. Agr., Bur. Anim. Indus. Bul. 86, pp. 18*).—Three degrees of infectiousness were artificially produced in milk by adding 1 loop of a culture of tubercle bacilli to 10 cc. of milk from which other degrees of infectiousness were obtained by diluting 10 times and 100 times. Guinea pigs fed on the milk which contained the largest number of tubercle bacilli became infected without exception after feeding on this material 30 days and in 33½ per cent of cases after being fed 1 day. Guinea pigs fed on milk containing a more dilute infection did not become diseased. Evidence was obtained, however, that guinea pigs are not very susceptible to infection with tuberculosis through the alimentary tract.

Hogs were inoculated subcutaneously with cultures of tubercle bacilli obtained from man and animals. In all 12 hogs were used in the experiments. It appears from these experiments that the high susceptibility of guinea pigs to tuberculosis holds good only when infection is made in the abdominal cavity, veins, thorax, or subcutaneous tissue. During the experiments, 52 guinea pigs and 6 hogs were fed on milk containing small quantities of tubercle bacilli, with the result that none of the guinea pigs were affected, while 5 out of the 6 hogs contracted tuberculosis. The experiments indicate clearly that the localization of tuberculosis in the lung gives no hint as to the point at which infection took place. The lung may readily become infected by tubercle bacilli which enter the body at some other point. The authors conclude that the experiments "direct special attention to the danger sustained through exposure to tuberculous material that enters the body with the food. This fact can not be too strongly emphasized."

Behavior of the cows' udder toward artificial infection with human and bovine tubercle bacilli, L. MEYER (*Ztschr. Tiermed., 10 (1906), Nos. 3, pp.*

161-197; 4, pp. 244-276).—An elaborate review is presented of the literature relating to this question in connection with a bibliography of 83 titles. In testing the virulence of tubercle bacilli of different origin, resort is usually had to the subcutaneous, intravenous, and intraperitoneal methods of inoculation. The author chose the method of injection into the udder without producing any lesion. In these experiments three cultures were used, two of human and one of bovine origin. The two cultures obtained from consumptive human patients failed to produce tuberculosis when injected into the udder of cows, and calves which drank the milk also remained healthy. The bovine tubercle bacilli, however, produced a general infection which involved not only the udder but various other organs and tissues and caused infection in the calf which drank the milk.

Tuberculosis of the male genital organs of cattle, J. KOWALEWSKY (*Rev. Gén. Méd. Vét.*, 7 (1906), No. 80, pp. 417-419).—It is stated that in Moscow, tuberculosis of the male genital organs of cattle was only observed in 1 case out of 74,389 which were inspected at slaughterhouses. On account of the unusual rarity of this form of tuberculosis the author gives detailed notes on two cases which came under his observation.

Tuberculin tests, N. O. NIELSEN (*Maanedskr. Dyrtaeger*, 18 (1906), No. 1, pp. 20-25).—The author undertook the application of the tuberculin test in his neighborhood for the purpose of determining the extent of infection. The results obtained were very satisfactory in so far as the reliability of the test is concerned. In one locality where 68 hogs were fed on the skim milk obtained from a creamery, 29 were found to be tuberculous. A system of pasteurization of the milk was consequently adopted.

Tuberculin and the organism, F. KÖHLER (*Tuberkulin und Organismus*, Jena: Gustav Fischer, 1905, pp. 100).—The extensive tests which have been reported with tuberculin in cows of different countries throughout the civilized world have led to differences of opinion regarding the reliability of tuberculin, its use for therapeutic purposes, and other matters connected with the general problem of tuberculosis. The author has presented in a brief manner a summary of results obtained by various investigators, the material being arranged under various subheads including chemical investigations, pathology, clinical studies, and therapeutic use of tuberculin. This summary of literature relating to tuberculin makes it apparent that while numerous facts have been worked out with tolerable certainty there still remain many doubtful points for further investigation before positive statements may be made regarding the effect of tuberculin upon the organism.

The demonstration of antituberculin and tuberculous tissue, E. WEIL and H. NAKAJAMA (*München. Med. Wchnschr.*, 53 (1906), No. 21, pp. 1001-1004).—An attempt was made to determine the specific effect of tuberculin upon tuberculous tissue, and in these experiments active serum was used after being rendered inactive by increasing doses of horse blood. The author believes that the experiments of Wassermann and Bruck proved merely that extractives from tubercle bacilli are found in tuberculous foci. The formation of the complement takes place as a result of a mixture of tuberculin and organic extract. It is believed possible that antituberculin may be present in tuberculous tissue, but this has not been proved. The author discards the theory that complement is formed by a chemical affinity between antituberculin and tuberculin.

The leucocyte and the tubercle bacillus, J. BARTEL and W. NEUMANN (*Centbl. Bakt. [etc.]*, 1. Abt., Orig., 40 (1906), No. 5, pp. 723-738).—In the experiments reported in this paper the authors made use of guinea pigs, rabbits, and dogs for inoculation, with an intent to determine the relationship between the leucocyte and the tubercle bacillus. It appears from these experiments that

in the struggle of the infected organism against tubercle bacilli neither the complement nor phagocytosis due to polynuclear and mononuclear cells exercises a decisive rôle. The phagocytosis which appears in a striking manner is largely due to the action of leucocytes found in the lymphatic glands or in other places where lymphocyte cells collect in large numbers.

A special method for cultivating tubercle bacillus on potatoes, J. ANZILOTTI (*Centbl. Bakt. [etc.], 1. Abt., Orig., 40 (1906), No. 5, pp. 765-768*).—By a combination of potatoes and glycerin, the author found it possible to bring about a more rapid and luxuriant growth of tubercle bacilli than by any other method with which he had experimented. The bacilli thus obtained appeared to remain in an active and virulent condition for long periods, and the virulence of the cultures was in many cases greatly increased.

The tubercle bacillus cultivated in a saccharine medium, L. VAILLIANT (*Compt. Rend. Soc. Biol. [Paris], 60 (1906), No. 15, pp. 741-743*).—The author added saccharose and glucose to a bouillon medium for the purpose of testing these substances. It appears from these experiments that saccharose and glucose exercise an effect on the amount of chloroform-bacilline produced by the tubercle bacillus.

A method for demonstrating anthrax bacilli in blood and tissues, J. FORSTER (*Centbl. Bakt. [etc.], 1. Abt., Orig., 40 (1906), No. 5, pp. 751-754*).—A simple method for demonstrating anthrax bacilli has been found in the use of gypsum. After allowing the suspected material to grow for some time on a gypsum rod, cultures are made from this material in order to subject them to microscopic examination. If such cultures are heated to a temperature of 65° C. for 2 minutes, other bacteria such as coli bacillus and proteus will be killed, while the anthrax bacilli will be unaffected.

Protozoan blood diseases of man and animals in German East Africa, A. TREUTLEIN (*München. Med. Wchuschr., 53 (1906), No. 18, pp. 855-857*).—Brief notes are given on the classification of the protozoa which are concerned in the production of blood diseases in man and animals. It was observed during investigations made in the region of Dares-Salaam that organisms resembling trypanosomes were frequently seen in blood preparations in cattle suffering from Texas fever or African coast fever.

Ticks and African coast fever, C. P. LOUNSBURY (*Agr. Jour. Cape Good Hope, 28 (1906), No. 5, pp. 634-654*).—The investigations of the author regarding the means of transmission of African coast fever have been continued. At first it was believed that only two species of ticks were concerned in transmitting this disease. It has been found, however, that 5 species are implicated—*Rhipicephalus appendiculatus*, *R. ercetsi*, *R. simus*, *R. nitens*, and *R. capensis*. Other ticks belonging to different genera apparently have nothing to do in transmitting African coast fever. In the author's experiments it was found possible to transmit the disease by means of one infected tick, but usually more were required. The incubation period averaged 13½ days and the duration of the disease 12 days. As a rule, the animals did not show serious symptoms until within a few days before death. Often it is impossible to transmit the infection by means of the ticks from diseased animals. In 35 cases positive results were obtained, and in all these cases the ticks had become infected in one stage of growth and communicated the disease in the succeeding stage.

Tissue alterations in the cows' udder in cases of sporadic galactophoritis, VAN DER LINDE (*Arch. Wiss. u. Prakt. Tierheilk., 32 (1906), No. 4-5, pp. 337-362, pls. 2*).—Detailed clinical notes are given on 35 cases of this disease. As a result of these studies the author comes to the conclusion that the udder of the cow exhibits a tubular character just before the period of lactation, while

during lactation it is an alveolar gland. Immediately after the close of the period of lactation it again becomes tubular in character. Sporadic galactophoritis appears to be a hypertrophic and polypous chronic catarrh of the udder. The lymphatic glands are enlarged and the catarrh appears to be due to a streptococcus.

A disease of young cattle in county Wexford, A. E. METTAM (*Dept. Agr. and Tech. Instr. Ireland Jour.*, 6 (1906), No. 3, pp. 460-476, pls. 2).—For several years a disease has prevailed among young cattle in the county of Wexford and is characterized by chronic diarrhœa, emaciation, and finally death. The chief symptom is progressive anemia and emaciation. An examination of the feces and of the intestines, post-mortem, showed the presence of *Strongylus gracilis* and fluke worms. Occasionally the lungs were infested with *S. micrurus*. In advanced cases the yellow marrow in the cavities of the long bones was replaced by red marrow. Various lines of treatment were adopted, such as the use of thymol, coal-tar creosote, carbolic acid, etc., and the feces were examined from day to day to note the effect of treatment. Recovery was brought about by the use of a tonic containing arsenic, tartar emetic, and sulphate of iron as well as by treatment with carbolic acid and turpentine, oil of tar, and thymol. In one case the recovery took place without any treatment. Creosote, lysol, tobacco, hyposulphite of soda, and various other remedies appeared to diminish the number of parasitic worms, but did not bring about a recovery. The author was unable to determine whether the stomach worms were the only cause of the disease. In one instance 28 animals in apparent health were examined and stomach worms were found in the feces of 24 of them. The disease seems, therefore, to be due to an excessive infestation with these worms.

Proliferation of connective tissue in the beef liver in cases of distomatosis, A. JAEGER (*Arch. Wiss. u. Prakt. Tierheilk.*, 32 (1906), No. 4-5, pp. 456-476, pls. 2).—The literature of this subject is critically reviewed in connection with a short bibliography. The author describes the various tissue changes which take place in the beef liver after infestation with flukes. A cirrhosis occurs in the form of an induration process, the cause of which is to be sought in the toxic metabolic products produced by the liver flukes in the bile ducts.

A hoof disease occurring in connection with foot-and-mouth disease, SCHENKL (*Wchnschr. Tierheilk. u. Viehzucht*, 50 (1906), No. 21, pp. 403-405).—The author had opportunity to observe a number of cases of hoof trouble which occurred in connection with foot-and-mouth disease. The parts chiefly affected were the crown of the hoof near the cleft and the internal walls of the cleft. The lesions consisted of ulcers in connection with which some proliferation of tissue took place. In a few cases the lesions extended to the bones of the foot. The affected tissue was removed and a thick layer of iodoform sprinkled on the diseased areas. Good results were obtained from this treatment.

Louping ill and braxy, D. J. HAMILTON ET AL. (*Jour. Bd. Agr. [London]*, 13 (1906), No. 3, pp. 135-142).—After a long series of experiments the existence of a specific bacillus was found in the exudate of the peritoneal cavity and subsequent tests show that the disease is of a bacterial nature. The organism is apparently taken into the intestines with the food. Much uncertainty has prevailed regarding the nature of braxy. The experiments by the committee appointed to investigate this disease indicate that a number of troubles commonly pass under the name braxy. It is believed that braxy, louping ill, blackleg, and malignant edema belong to the same group of diseases. In fact, the similarity between the symptoms of the louping ill and braxy is so close that confusion often occurs in reaching a diagnosis. It was found that at certain seasons of the year the blood of sheep is quite resistant to the organisms of

both diseases, while at other times it is highly susceptible to their action. The fatal effect of the pathogenic bacteria may, therefore, be prevented in part by drenching the sheep with cultures of these bacteria during the periods of resistance.

Diseases of swine, R. A. CRAIG (*New York: Orange Judd Co., 1906, pp. 191, figs. 23*).—In view of the agricultural importance of swine raising the literature relating to swine diseases may be considered as too much scattered to be available for practical use by the farmer. The author has attempted in the present volume to bring together the known facts relating to the common diseases of pigs. The subject-matter is discussed under a number of heads, including general, surgical, infectious, and parasitic diseases. Particular attention is given to a thorough discussion of the serious infectious and parasitic diseases of hogs.

The hog-cholera group of bacteria, J. CITRON (*Ztschr. Hyg. u. Infectiouskrankh., 53 (1906), No. 1, pp. 159-175*).—In the author's experiments particular attention was given to a study of agglutinins and aggressins and other bacterial substances contained in the hog-cholera group. It was found that monovalent hog-cholera serum agglutinates the organisms of hog cholera, paratyphoid, and mouse typhoid. The most of the bacteria belonging to this group, when studied in vitro, show a very slight absorptive power for antibodies. While a study of the cultural characters and serum reactions of bacteria of this group indicates a close relationship between the different members, the author nevertheless believes that more study must be devoted to the group before it is safe to consider the organisms of hog cholera, mouse typhoid, and paratyphoid as identical.

Immunization of hogs against swine plague by means of aggressin, E. WEIL (*Centrl. Bakt. [etc.], 1. Abt., Orig., 41 (1906), No. 1, pp. 121-125*).—Attention is called to the difficulties which have been experienced in producing immunity against the various forms of hemorrhagic septicemia, to which group swine plague belongs. By means of aggressin, however, many of these difficulties are overcome, and according to the author's experiments excellent results are obtained. It was found in experiments with rabbits that when these animals were immunized against swine plague by a single injection of aggressin obtained from hogs, an immunity was produced which protected them against inoculation with virulent cultures nearly 5 months later. In experiments with hogs it was found that the aggressin in order to be perfectly effective should come from other hogs rather than from rabbits. When rabbit aggressin was used it appeared that 2 inoculations of 10 cc. were enough to protect the animal against a fatal dose of swine-plague culture. It seems that for a short time after inoculation with aggressin and before this material has become effective, the animals are unusually susceptible to swine plague and more likely to take the disease than are those which have not been treated with aggressin.

Intestinal emphysema of hogs, A. JAEGER (*Arch. Wiss. u. Prakt. Tierheilk., 32 (1906), No. 4-5, pp. 410-455, pls. 3*).—Considerable attention has been given to this peculiar condition which is quite often met with in hogs, and no specific cause has heretofore been definitely assigned for it. According to the author's investigations, based on a large number of cases and on the bacteriological study of the tissues involved, this disease must be considered as a local infection in the small intestines, in which the most important processes take place in the lymphatic vessels. The disease is said to be due to a specific organism referred to as *Bacillus coli lymphaticus ucrogenes*. Inoculation experiments were made with the organism in question, as a result of which the characteristic vesicles containing gas developed along the walls of the intestines and bacteria were again recovered in pure cultures.

Treatment of tetanus, DESOUBRY (*Bul. Soc. Cent. Méd. Vét.*, 83 (1906), No. 10, pp. 271-274).—The author has had considerable experience in treating tetanus, especially in horses, and discusses the effectiveness of different methods. In a recent case of tetanus which occurred in a colt, antitetanus serum was administered intravenously in a dose of 30 cc., together with 10 cc. of tallianin. The treatment was continued for 3 days and diuretin and benzoate of caffein were also given. At first there was improvement, but later serious symptoms recurred. Tallianin was then administered regularly and the animal finally recovered.

Trypanosomiasis of horses in Annam, J. J. VASSAL (*Ann. Inst. Pasteur*, 20 (1906), No. 4, pp. 256-295, fig. 1).—An outbreak of trypanosomiasis occurred near the Pasteur Institute in Annam and was investigated by the author. An account is presented of the distribution of the disease; the symptoms as observed in various cases; inoculation experiments with isolated micro-organisms in rats, guinea pigs, rabbits, and monkeys; and on the pathological lesions observed in affected animals. The author devotes considerable attention to a discussion of the relationship of this disease to surra and comes to the conclusion that it differs somewhat from surra as observed in Iuida, Mauritius, and Java by the slighter susceptibility of cattle and the greater virulence of the organism for other animals. On the whole, however, the disease appears to be practically identical with surra.

Horse botflies and their importance in raising colts, KRÖNING (*Ztschr. Veterinärk.*, 18 (1906), No. 5, pp. 202-211).—During the past 5 years the author has had occasion to observe many cases of cachexia accompanied with colic in young colts. Notes are given by way of differential diagnosis between botfly disease and chronic anemia, leukemia, pseudoleukemia, infestation with stomach worms and tabes intestinalis. As a result of numerous observations it is concluded that botfly larvæ in large numbers may greatly injure the health of horses. Notes are given on *Gastrophilus equi*, *G. pecorum*, *G. hemorrhoidalis*, and *G. nasalis*. The author made special observations on 31 cases of botfly disease in horses. Among this number, 23 young colts recovered after receiving carbon bisulphid in doses of 8 gm. each repeated 6 times.

The army horseshoer, E. A. DOWD ET AL. (*Fort Riley, Kans.: U. S. War Dept.*, 1905, pp. 84, pls. 22).—This volume was prepared for use in the school of application for cavalry and field artillery in Fort Riley, Kansas. It contains an account of the anatomy and physiology of the horse's foot, tools used for horseshoeing, methods of shoeing the normal foot, and special methods to confirm or alter certain gaits in the horse as well as an account of disease of the foot. The illustrations are mostly from photographs of army practice in shoeing horses and are of good quality.

The rapid diagnosis of rabies, L. FROTHINGHAM (*Jour. Med. Research*, 14 (1906), No. 3, pp. 471-489, pls. 3).—On account of the recent extensive outbreak of rabies in Massachusetts, the author took occasion to test two of the most generally recognized methods for the rapid diagnosis of rabies. These methods are based on pathological changes in the nerve ganglia and on the presence of Negri's corpuscles. The pathological lesions in the nerve cells, particularly in the plexiform and Gasserian ganglia, are easily demonstrated and, according to the investigations of the author, constitute a source of diagnosis which is fairly accurate. In all cases examined by the author these lesions were presented, sometimes where it was impossible to demonstrate Negri's corpuscles. It was not thought wise, however, to depend entirely on these methods, since in one instance lesions were found in a case which was apparently not rabies.

The results obtained from Negri's method were always positive in cases where the corpuscles were found and since the method seems to be perfectly reliable to that extent it is considered useless to sacrifice animal life in making inoculations when the corpuscles are found. A detailed tabular statement is presented of the various animals examined and of the findings of Negri's bodies and lesions in the Gasserian ganglia.

The significance of Negri's corpuscles in the diagnosis of rabies, W. ERNST (*Monatsh. Prakt. Tierheilk.*, 17 (1906), No. 9-10, pp. 453-466, figs. 3).—The author made a careful study of the nature and occurrence of Negri's corpuscles in animals affected with rabies. As a result of these investigations it was found that in 96 to 99 per cent of the cases of rabies in which clinical symptoms have appeared, intracellular structures are found in the central nervous system which do not appear in healthy animals or in the case of any other disease. The microscopic recognition of rabies by this means is possible even when, on account of decomposition of the material, no help could be expected from inoculation tests. In all cases where Negri's corpuscles are found the diagnosis of rabies is considered perfectly reliable and inoculation tests may be omitted. The diagnosis may be made with a certainty within 3 to 4 hours by means of an embedding method calling for the use of acetone and paraffin. It still remains doubtful whether Negri's corpuscles are a developmental stage of the rabies organism or a product of cell reaction to the disease.

Negri's corpuscles in rabies, N. BALL (*Arch. Vet. Nauk [St. Petersburg.]*, 36 (1906), No. 3, pp. 153-170, figs. 2).—The literature relating to this subject is critically discussed in connection with a short bibliography. The author presents in a tabular form the results obtained by various investigators in an examination of the brain tissue of rabid animals for the presence of Negri's corpuscles. As a result of the author's study, it is concluded that approximately 96.5 per cent of animals affected with rabies show peculiar structures known as Negri's corpuscles in the nerve cells, particularly in Ammon's horn. In healthy animals or in animals affected with any other disease than rabies, Negri's corpuscles are not to be found in the nerve cells. These bodies, therefore, constitute an excellent means of diagnosis which may be accomplished within 5 to 7 hours after the post-mortem examination of the animal in question. The absence of Negri's corpuscles in the nerve cells of animals suspected of rabies does not exclude the possibility of rabies being present.

The toxin produced by *Aspergillus fumigatus*, E. BODIN and L. GAUTIER (*Ann. Inst. Pasteur*, 20 (1906), No. 3, pp. 209-224).—From the study of this fungus in cultures and in experimental animals it was found that *Aspergillus fumigatus* produces a toxin which may be rightfully compared with the toxins of bacteria. For the formation of this toxin in cultures it is necessary to have a mixture of protein, especially of the peptone type, and some carbohydrate, especially glucose, saccharose, maltose, or dextrin. The reaction of the toxin must be either neutral or alkaline. The effects of the toxin are chiefly observed in the nervous system and are produced more or less rapidly by the method of inoculation. The symptoms of poisoning from the toxin are muscular convulsions resembling tetanus and leading to death within a few hours if the animal does not recover. The rabbit and dog are very susceptible to the toxin, while the guinea pig, cat, mouse, and white rat are more refractory. The dog and cat are naturally immune to the spores of *A. fumigatus*, but are quite susceptible to the toxin produced by the fungus.

Chicken pox: The forms of chicken pox and their relation to true pox and their micro-organisms. REISCHAUER (*Centbl. Bakt. [etc.]*, 1. Abt., Orig., 40 (1906), Nos. 3, pp. 356-361; 4, pp. 474-479; 5, pp. 653-683, pls. 2).—The

common chicken pox, also known as epithelioma contagiosum, has long been known in veterinary science and appears to be distributed throughout the civilized world where fowls are kept. The symptoms of this disease consist essentially in tuberculous exanthema of the skin and specific alterations of the visible mucous membranes. Some fever also accompanies the disease and it is highly contagious. The pathological histology of chicken pox is described in some detail. It appears that in many cases the processes observed in the throat are of a diphtheritic nature and the micro-organisms concerned are perhaps of a saprophytic type which, under certain conditions, penetrate into the living tissue. The micro-organisms found in chicken pox closely resemble those observed in other kinds of pox which affect mammals, and these micro-organisms are distributed in a very similar manner throughout the body. All forms of pox, therefore, seem to be somewhat closely related. Definite statements concerning the relationship, however, can not be made with any safety. A bibliography of this subject is appended to the article.

Cachexia due to *Syngamus trachealis* in pigeons, R. P. Rossi (*Clin. Vet. [Milan]*, 29 (1906), No. 4, pp. 73-82).—An extensive infestation of gapeworms was noted by the author in a colony of pigeons. The gapeworms were occasionally found in the esophagus of young pigeons and obviously young birds became infested through the food given them by the parent birds. Many of the young pigeons died as a result of esophageal infestation. The parasites were frequently observed in the trachea and occasionally in the bronchi of adult pigeons, in which situation they caused a cachectic state and occasionally death by asphyxiation.

RURAL ENGINEERING.

Interstate royal commission on the River Murray, representing the States of New South Wales, Victoria, and South Australia (*Rpt. Comrs. (Sydney)*, 1902, pp. 359, *dgms. 15, maps 12*).—In 1901 there was appointed a royal commission representing the three States of New South Wales, Victoria, and South Australia, whose duty it was to recommend a plan for controlling and utilizing the river Murray, which forms the boundary between New South Wales and Victoria and flows through the territory of South Australia. This commission favors the abrogation of the doctrine of riparian rights and the subordination of navigation to irrigation, but recommends that navigation be maintained by means of locks. It recommends the delivery of a fixed quantity of water from the main stream to each of the three States and a pro rata reduction in case of shortage, and that the torrential tributaries be left to the control of the States in which they are situated. It is recommended further that the carrying out of this agreement be placed in the hands of a special commission to be created by agreement between the three States, the commission holding that this work could not be properly done by the federal officials.

The report gives much interesting information as to present development and the schemes which have been adopted for supplying the capital necessary for the construction of irrigation works. In Victoria the government has built the main canals, and the distributing ditches have been built by local organizations with funds loaned by the government. The report states that in no case have these local organizations lived up to their agreement with the State. In Victoria £1,000,000 out of a total of £1,300,000 of obligations of these associations have been canceled by the State. In New South Wales the works have been built by the government without any provision for the return of the money invested.

In South Australia attempts have been made to provide for the unemployed by settling them upon irrigated tracts, these colonies usually being communistic. None of them has succeeded.

Suggestions for the construction of small pumping plants for irrigation, F. H. NEWELL (*Irrig. Age*, 21 (1906), No. 9, pp. 270-274, figs. 5).—This article outlines the construction of plants adapted to pump water from wells sunk in gravels. The author suggests that such wells should be 12 to 15 in. in diameter sunk into water-bearing gravel 30 to 60 ft., strainers of slotted galvanized iron being provided through the gravel strata. He states that "a 15-in. well drilled in good water-bearing gravel to a depth of 40 ft., the lower 30 of which is strainer surface, should supply at least 300 gal. per minute when the pump lowers the level in the well by 10 ft." For large-size plants the writer recommends arranging a battery of wells in pairs, all being connected to the suction pipe. The arrangement in pairs is for the purpose of removing fine sand from the gravel between the wells, by pumping from one of the pair of wells while running clear water into the other. The inclosed runner type of centrifugal pump, "long sweep" fittings, and internal combustion motors are recommended. For plants of 20 to 30 horsepower the installation of gas-producer plants is advised, since at \$8 per ton the cost of coal should be equivalent to gasoline at 4 to 6 cts. per gallon. With regard to the economical height to which water may be lifted, the author considers that "it is very unlikely that it will pay to pump water under present conditions in the valleys of the western plains to a total height of more than 30 ft., including the suction lift of the pump." Data are also given on the cost of pumping and first cost of plants.

Agricultural machinery in the United States (*Landw. Masch. u. Geräte*, 6 (1906), No. 12, p. 5).—In speaking of the economy resulting from the use of machinery in farming operations in the United States, Dr. Laughlin, of Chicago, gave the following figures before a political economy society in Berlin: The sowing of grains which formerly required 10 hours and 35 minutes by hand can now be accomplished in 32.7 minutes by machinery; harvesting and thrashing which required 46 hours and 40 minutes by hand can now be done in 1 hour by machinery. The time required for planting of corn of 6 hours and 15 minutes has, through aid of machinery, been reduced to 37.5 minutes; husking operations requiring formerly 65 hours 40 minutes now require 3.6 hours. The mowing machine performs in 1 hour and 6 minutes what a man with a scythe formerly could accomplish in 7 hours and 20 minutes. Potato planters will now plant as many potatoes in 1 hour and 25 minutes as formerly required 15 hours to accomplish by hand.

Test of American manure-spreading machine (*Maschinen Ztg.*, 4 (1906), No. 12, pp. 137, 138, fig. 1).—A discussion of the report on a public test of a manure-spreading machine manufactured in the United States. It is concluded from this test that while the machine does excellent work its value to the farmer is reduced because of its high price and the excessive power required in its operation. It is predicted, however, that it will find extensive use in Germany.

Two tools for the culture of root crops (*Maschinen Ztg.*, 4 (1906), No. 11, pp. 128, 129, fig. 1).—One of these is a hoe of special shape provided with markers; the second is a tool for transplanting roots, consisting of an open conical tube, the lower end being sharpened to a cutting edge and a handle being attached to the upper end. The tube is thrust into the ground around the root and the whole plant is removed without disturbing the soil immediately surrounding the root and root hairs. Owing to the conical shape of the tube it is claimed that the operation of withdrawing the tube after the plant is in its new position is comparatively easy.

Plowing by electricity at Dahwitz (*Maschinen Ztg.*, $\frac{1}{4}$ (1906), No. 12, pp. 137, 135, figs. 2).—The apparatus in use here consists of a gang plow which is alternately moved back and forth across the field between two "anchor wagons." By this apparatus about 2 $\frac{3}{4}$ acres per hour are plowed, and the cost, taking into account all operating expenses and interest on cost of equipment, including power plant, amounts to \$0.61 per acre. While it is claimed that the use of the apparatus has proven profitable in this case, it is pointed out that this would not in general be true except probably in those cases where the electric plant could be operated continuously throughout the year, the power generated being put to other profitable uses when not used for plowing.

The windmill in agriculture, C. E. LAWFOED (*Agr. Jour. Cape Good Hope*, 28 (1906), No. 2, pp. 200-205, figs. 6).—After calling attention to the defects in the mills at present being employed in South Africa and elsewhere, the writer urges the following improvements: More rigid and stronger frames, provided with good ladders and large roomy platforms surrounded by railings; a tower cap provided with large rings and burnished-steel balls; a gear head with easily "get-at-able" bearings and a band brake capable of holding the wheel in the highest winds with a minimum power. To increase the efficiency of the mechanism the writer recommends roller bearings in the gear head and a mangle motion in substitution for the usual crank and pitman arrangement. He advises the use of two pumps—one for light breezes and the other for combination with the first in the case of heavy winds. As to oiling devices, he thinks the endless chain or ring oiler the best for solid bearings, and syphon cups with compound, soft-iron wire wicks the best for roller bearings. The writer thinks that "power mills" have certain essential advantages over the usual form, particularly in the efficiency with which the power is transmitted from the wheel to the pump.

The utilization of solar heat for industrial purposes by means of a new plane-mirror reflector, C. GÜNTNER (*Sci. Amer. Sup.*, 61 (1906), No. 1586, pp. 25709-25712, figs. 6).—This is a description of a new form of reflector devised by the author, which has certain features radically different from the conical-shaped reflectors of other inventors. His device consists of a series of plane mirrors arranged in a horizontal position and supported by a peculiar link work which is moved to conform to the position of the sun, and which maintains the mirrors in such position that the sun's rays are projected upon a long cylindrical boiler. The latter lies above the mirrors in a horizontal position, with its axis in a north and south direction. The mechanism is such that the mirrors can be turned completely over about their axes as a protection in case of hail-storms. From experiments it was found that a reflector with a surface of 1,000 sq. ft. delivered in 12 hours an amount of energy equal to that generated by the consumption of 4,400 lbs. of hard coal, this being in European latitudes. The inventor estimates that the reflectors can be built at an expense of about \$2 per square yard of surface, and predicts that because of its simplicity, cheapness, and effectiveness it will be useful as an aid to pumping operations in arid regions and for other uses in localities where fuel is scarce and sunshine abundant.

Tests of the relative value of crude oil (Beaumont, Texas), kerosene, and gasoline (*New Mexico Sta. Rpt.* 1904, pp. 29-31).

RURAL ECONOMICS.

Rural economy. G. N. LAUMAN (*Cornell Countryman*, 3 (1906), No. 9, pp. 211, 212).—In this article rural economy is tentatively outlined as "that field of knowledge dealing with the facts, deductions, and theories concerning the

economic side of agriculture." The author calls attention to the difference in division of the subject that has taken place in Europe and the United States, and points out that in the latter the agricultural colleges are developing the subject of rural economy rather than that of general economics.

The transition in agriculture, E. A. PRATT (*London: John Murray, 1906*, pp. X + 354, pls. 10, figs. 2).—The author shows in this volume the changes which have taken place in English agriculture during the past few years as a result of the decline in cereal production in Great Britain.

As a result of foreign competition, the conservative English farmer has largely given up the culture of wheat and other cereals and is yielding to the advantages of agricultural cooperation in methods of producing, collecting, shipping, and marketing poultry and dairy products, vegetables, fruits, flowers, etc. The opportunities open to the British producer along these lines are shown by the fact that articles of agricultural production, the bulk of which consists of food supplies, were imported into the United Kingdom in 1905 to the value of nearly \$1,100,000,000. The author maintains that "though in our circumscribed limits we might not be able to become absolutely self-supporting in regard to all these things, we could certainly produce them for ourselves in greatly increased quantity."

The continued development of British agriculture along the lines of combination and improved marketing conditions, the improvement of the present tenant system, and the further extension of the cooperative allotment of land to factory workers and others near large towns as a means of training for farm and horticultural work and improving their financial condition are earnestly urged upon the attention of the British government, because they "represent the present-day hope of the British agriculturist." To this end the author concludes that the government "should carry out a scheme for the promotion of agricultural education on essentially practical lines; that experimental farms, especially in connection with fruit culture, should be set up in every district where they are likely to be of direct service; that assistance should be given in the setting up of agricultural credit banks; and that a more generous measure of financial support should be extended to the Board of Agriculture and Fisheries with a view to enabling it to increase its powers of usefulness to the agricultural community."

Crop Reporter (*U. S. Dept. Agr., Bur. Statis. Crop Reporter, vol. 8, Nos. 1, pp. 1-8; 2, pp. 9-16*).—These numbers for May and June contain the usual statistical matter on the condition of crops in the United States and foreign countries. Special reports are also included on the beet-sugar production of the United States and Canada; ocean freight rates on cotton; grain crops of the provinces of Alberta and Saskatchewan; outlook for tobacco, 1906; world's international trade in wool; exports of cattle; and other topics.

Cotton production and statistics of cotton-seed products, 1905, W. M. STEUART and D. C. ROPER (*Bur. of the Census [U. S.] Bul. 40, pp. 72, maps 2, dgm. 1*).—In 1905 the total crop of cotton ginned, counting round as half bales, amounted to 10,725,602 bales, of which 10,242,648 square bales and 279,836 round bales were upland cotton, 112,539 Sea Island, and 230,497 bales linters. The average production of cotton for the last 4 years is given as 11,339,323 bales, or 534,767 bales more than in 1905. The production of cotton for several years is given in tables by States and counties and cotton culture in the different cotton-producing countries of the world is described. A table is also given summarizing the cotton-seed products industry, showing capital invested, number of employees, salaries and wages, miscellaneous expenses, cost of materials, and value of products, by States and Territories, for 1890, 1900, and 1905.

Virginia, its forests, minerals, and agricultural possibilities, D. A. WILLEY (*Tradesman*, 55 (1906), No. 5, pp. 51, 52).—The agricultural possibilities in the lines of market gardening and tobacco growing especially are discussed.

How to keep farm accounts, H. L. STEINER (*Toledo, Ohio: Steiner & Co., 1905, pp. 150*).—This book is designed to present a simple form of keeping farm accounts by means of a ledger only. Practical illustrations of making entries, striking balances, etc., are presented.

Farm accounts, J. A. VYE (*St. Paul, Minn.: Author, 1906, pp. XIII + 141, pls. 3, figs. 3, dymms. 47*).—This book is an outgrowth of class-room work and is designed as a manual for the farmer who is desirous of knowing how to keep an accurate account of his business. The entries are made on cards instead of in books, this method being advocated as best for the farmer because of its simplicity and comprehensiveness.

MISCELLANEOUS.

Eighteenth Annual Report of Colorado Station, 1905 (*Colorado Sta. Rpt. 1905, pp. 64*).—This contains a financial statement for the fiscal year ended June 30, 1905; a report of the director on the work of the station during the year; an inventory of the station for 1905; a list of exchanges; and reports of the heads of departments, parts of which are abstracted elsewhere in this issue. The report of the Arkansas Valley field agent contains notes on experimental work with cantaloupes, beets, alfalfa, and corn.

Publications of Colorado Station, 1903-4 (*Colorado Sta. Pubs. 1903-4, pp. 530, figs. 38*).—This consists of Bulletins 77-95 of the station, Press Bulletins 16-23, and the annual report for 1904.

Annual Report of Florida Station, 1905 (*Florida Sta. Rpt. 1905, pp. 5-52*).—This contains a report of the director on the work of the station during the year; a financial statement for the fiscal years ended June 30, 1904 and 1905; departmental reports, some of which are noted elsewhere; and lists of exchanges and publications of the station.

Annual Report of New Jersey Stations, 1905 (*New Jersey Stas. Rpt. 1905, pp. XIX + 689*).—This includes the organization lists of the stations; a financial statement of the State station for the year ended October 31, 1905, and of the college station for the fiscal year ended June 30, 1905; a report of the director reviewing the different lines of station work; and departmental reports abstracted elsewhere. Two reports on feeding stuffs have been noted from other publications (E. S. R., 17, pp. 275, 276).

Fifteenth Annual Report of New Mexico Station, 1904 (*New Mexico Sta. Rpt. 1904, pp. 48*).—This contains a financial statement for the fiscal year ended June 30, 1904, and reports of the director and heads of departments, parts of which are abstracted elsewhere in this issue.

Sixteenth Annual Report of North Dakota Station, 1905 (*North Dakota Sta. Rpt. 1905, pp. 55*).—This contains reports of the director and heads of departments on the work of the station during the year 1905, and a financial statement for the fiscal year ended June 30, 1905. The experimental work contained in the report is abstracted elsewhere.

Digest of the work of the Ploti Agricultural Experiment Station for the decade 1895-1904, A. A. BICHUKHIN ET AL. (*Svod Rabot Plotyanskoj Selsko-Khozyaistvennoj Opuitnoj Stantsii. Odessa, 1905, pp. XV + 294, figs. 9*).

NOTES.

Arizona Station.—G. E. P. Smith, irrigation engineer, has inaugurated an investigation into the amount, availability, and value of the underground water supply in a representative arid-region valley. The station has instituted work in vegetable physiology and pathology, and W. B. McCallum, Ph. D., of the University of Chicago, has been selected to have charge of this work. He will enter upon his duties about January 1, and will take up the study of certain plant diseases peculiar to the region. Edward E. Free, a recent graduate in chemistry at Cornell University, has been appointed assistant chemist.

California University.—The title of M. E. Jaffa has been changed from assistant and professor of agriculture to assistant professor of nutrition.

Connecticut College and Storrs Station.—W. M. Esten has succeeded W. A. Stocking, jr., as dairy bacteriologist in the college and station.

Delaware College and Station.—Harry Hayward has accepted the position of director of the station and professor of agriculture in the college. He will assume his duties October 1.

Florida University and Station.—C. M. Conner has resigned as agriculturist and vice-director, to accept the position of agriculturist in the North Carolina College. W. R. Clothier of Kansas has been appointed to succeed him as agriculturist.

Indiana Station.—C. O. Swanson has resigned as assistant chemist to accept a similar position at the Kansas Station. L. S. Hasselman, a graduate of Purdue, class of '06, has been added to the chemical department as assistant chemist. C. O. Cromer, a graduate of Purdue, class of '06, has been appointed assistant agriculturist. H. N. Slater, dairy field assistant, has been appointed expert in the Dairy Division of this Department, in charge of extension work in dairying in Texas. G. I. Christie has been transferred from assistant in crop improvement to associate in charge of agricultural extension.

Iowa College and Station.—J. A. McLean, in charge of animal husbandry at the Colorado College and Station, has been elected assistant professor of animal husbandry in the college and assistant animal husbandman in the station, to succeed W. J. Rutherford, resigned. E. T. Robbins, assistant in animal husbandry in the college, will hereafter devote all of his time to station work as assistant in animal husbandry. M. E. McCulloch, E. Humbert, and L. C. Burnett have been elected assistants in the farm crops department. The poultry department recently established at the college has been placed in charge of H. C. Pierce, of Ithaca, N. Y. M. L. King, a graduate of the mechanical engineering department of Iowa State College, has been elected experimentalist in agricultural engineering.

An agricultural extension department has been organized, with P. G. Holden as superintendent. He will have a corps of six or seven assistants, who will be specialists in the subjects of animal husbandry, soils, dairying, farm crops, horticulture, and domestic science. The total staff in the division of agriculture, including the instruction staff, the experiment station, and the extension work, will number 41 this year.

The funds from the Adams Act and increased State appropriations have enabled a more clearly defined distinction between the experimental, instructional, and extension work than has formerly been the case. Thirteen of the members of the staff will devote their time exclusively to station work. Eight of the members of the instruction staff will devote their time exclusively to instruction work. The heads of departments will have the general direction of the work in both lines, but the assistants are in most cases assigned definitely to one field or the other.

Kansas College and Station.—C. W. Burkett, of the Ohio State University, has been elected director of the station, and entered upon the duties of his position September 1. C. O. Swanson, assistant chemist of the Indiana Station, has been elected assistant chemist, his term of service beginning September 1. W. E. Mathewson, assistant in chemistry in the college and station, has resigned his position and will spend the next year or two in study. C. W. Melick, assistant in dairying for the past two years, has resigned to accept a position at the Maryland College and Station.

Special trains for the improvement of wheat growing were run through the wheat belt over the Atchison, Topeka and Santa Fe Railway and Union Pacific Railway during August. The trains were provided by the railroads, and the other expenses were borne by them to a large extent. Meetings were held in the coaches during the day and at halls in the evening where practicable. Much interest was taken by the farmers in these meetings, and it is believed that they will be of material benefit to the wheat growers.

Maryland Station.—P. M. Novik, of Cornell, has been appointed assistant in the horticultural work under the State appropriation. George P. Weldon, of Fort Collins, Colo., has been appointed assistant entomologist and assigned to the State work. F. H. Blodgett, assistant botanist and pathologist, has been granted one year's leave of absence, and E. I. Lichti, of Columbus, Ohio, has been appointed to fill this vacancy. V. M. Shoemith, now associate agronomist at the Kansas Station, has been appointed agronomist of this station, to take effect January 1, 1907. This work has been carried on by Professor Taliaferro, who in the future will confine himself to college work. W. N. Hutt has resigned the position of horticulturist to accept a similar place in North Carolina. His resignation takes effect November 1.

Massachusetts College and Station.—Clark Hall, the new botanical building provided for by the last session of the legislature, is now in process of erection. The appropriation for the building is \$45,000. It will be 45 by 95 ft. in dimensions, and two stories in height above a basement, and with an attic which will contain several good rooms. The base will be of granite and the rest of the building of red brick with marble trimmings. The roof will be of copper and slate. The building will be of slow-burning construction, and special provision will be made in the construction of the desks and other laboratory fittings to avoid fire hazard.

The last State legislature appropriated \$5,000 for normal work at the college, as a result of the report of the industrial commission, made last summer. The exact character of this work has not yet been determined upon, but it is planned to promote agricultural instruction in the elementary grades. The State industrial commission is continued, with Prof. Paul H. Hanus, of Harvard University, as chairman, and it is hoped that the above appropriation will be only a beginning of a new line of work at the college.

Montana College and Station.—Dean B. Swingle, for several years connected with the Bureau of Plant Industry of this Department, has been appointed assistant botanist in the station. A greenhouse 22 by 50 ft. has been con-

structed, at a cost of about \$1,000, for use in connection with the botanical work of the college and station.

Nevada University and Station.—N. E. Wilson, for 15 years chemist of the station, and more recently in charge of the chemical work of the university, has been granted a two-years' leave of absence. He will be the manager of a large wholesale and retail drug business, with an analytical laboratory connected. Dr. Maxwell Adams, a graduate of Stanford University, assumes his work as professor of chemistry in the university, and S. C. Dinsmore, assistant chemist, will have charge of the station work.

New Hampshire College and Station.—F. W. Rane, horticulturist in the college and station, has resigned to accept the position of State forester of Massachusetts, with headquarters at Boston. The former forester, Alfred Akerman, resigned during the summer to accept a position elsewhere.

New York State Station.—W. E. Tottingham, assistant chemist, has resigned his position to become instructor in agricultural chemistry at the University of Wisconsin. H. J. Enstace, assistant botanist, has accepted a position in the Bureau of Plant Industry, this Department.

Oklahoma College and Station.—F. C. Burtis has resigned his position in charge of animal husbandry, and has been succeeded by W. F. McDonald, of Teeswater, Canada. L. A. Moorhouse has returned from a year's leave of absence and taken charge of the department of agronomy.

Rhode Island Station.—Leon J. Cole, Ph. D., of Harvard University, has been appointed chief of the division of animal breeding and pathology. W. F. Purrington, of the New Hampshire College, and H. S. Hammond, of the Ontario Agricultural College, have been appointed assistant chemists in the station.

A new horticultural building and greenhouse is being built with a State appropriation of \$15,000. Accommodations for station work will be provided in one wing of the greenhouse.

Virginia Station.—Seymour M. Herrick, a graduate of Cornell University, has been appointed assistant chemist. Cooperative arrangements have been made between the U. S. Department of Agriculture, the State board of agriculture, and the Virginia Station, for work in the trucking region of the State. The new agricultural hall is nearing completion. Arrangements have been made for the construction of two large fermentation cellars, which will be artificially refrigerated, for the purpose of studying the production of vinegar and other fermented products of the apple.

Washington Station.—H. R. Watkins, instructor in chemistry at the Kansas College, has been appointed assistant chemist in the station.

West Virginia Station.—The death is reported of A. L. Post, assistant bacteriologist in the station.

Experiment Station for Economic Botany in Sweden.—The establishment of a botanical experiment station near Landskrona, Sweden, is noted in the *Scientific American*. This station, named Esperanza, which has been established by a bequest of Oscar Ekman, is intended solely for investigations of an economic nature, such as the cultivation of medicinal, pigment, and fiber plants. The station was dedicated in July and consists of a museum and experimental fields. Two directors have been appointed, Tom von Post, a practical botanist, formerly director of the seed-control station at Upsala, and author of the *Lexicon Generum Chanerogamarum*, and Hjalmar Lindström, in charge of the pharmaceutical side of the work.

Bacteriological Laboratory at Rothamsted.—On July 19 at the Rothamsted Experiment Station occurred the formal opening of a new laboratory erected and partially endowed (\$250 a year) by J. F. Mason, M. P., in memory of his

father, the late James Mason, of Eynshan Hall, Oxon, who for many years conducted on his own estate extensive experiments on the influence of leguminous crops on fertility. The new laboratory is said to be the only one in England devoted exclusively to the study of agricultural bacteriology.

Agricultural Education at the American Institute of Instruction.—The seventy-sixth annual convention of the American Institute of Instruction was held at New Haven, Conn., July 9-12. In the department of rural education the papers and discussions were devoted largely to the subject of elementary agriculture. Hon. Walter E. Ranger, commissioner of public schools in Providence, and Mr. Frank E. Murdock, principal of the North Adams, Mass., Normal School, discussed *The Significance of the Report of the Massachusetts Commission on Industrial Education*. Hon. Mason E. Stone, superintendent of education of Vermont, and Dr. William P. Brooks, of the Massachusetts Agricultural College, considered the subject *Have the Principles of Agriculture a Legitimate Place in the Curricula of the New England Public Schools?* *The School Garden as an Instrument of Sound Education* was the subject of a paper by W. H. Baldwin, principal of the State Normal School at Hyannis, Mass., and *The Preparation of Teachers for School Garden Work* was presented by H. D. Hemenway, of Westchester, Conn.

California Polytechnic School.—A new two-story domestic science building, 42 by 103 feet, is just being completed. It contains on the first floor an office and reception room, 2 sewing rooms with adjoining cloak room, closets, and fitting room, a lecture room and a class room for classes in botany with adjoining office and herbarium. On the second floor are the kitchen, laboratory, pantry, butler's pantry, lockers, dining room, office, 2 class rooms (one for bookkeeping), and rest room.

Agricultural High Schools in Georgia.—The last general assembly of Georgia passed a law establishing 11 Congressional agricultural high schools as branches of the State College of Agriculture, to be under the general supervision of the board of trustees of the University of Georgia. Each school will receive for maintenance an equal share of the inspection fees collected by the State department of agriculture not otherwise appropriated, amounting as now estimated to about \$6,000 a year, but the different localities in which the schools are located must furnish not less than 200 acres of land and the necessary equipment. The course of study will be limited to the English branches, agriculture, farm mechanics, and such other studies as will admit a boy to the freshman class of the State College of Agriculture. It is contemplated that the boys will perform all the work on the farms and about the school property, and will receive wages from the proceeds of the farms.

New Agricultural High Schools.—The school board of Cecil County, Md., has decided to open this fall an agricultural high school at Calvert, in the northern part of the county, and has engaged Mr. H. O. Sampson, of this Department, as superintendent and teacher of agriculture. The recent legislature of the State passed an act requiring agriculture to be taught for at least one year during a child's connection with the public schools, and this subject will appear in the next manual of studies issued by the State superintendent of public instruction.

A new high school has been opened at Petersham, Mass., with a course in agriculture. Edwin H. Scott, a graduate of the Massachusetts Agricultural College, is instructor in that department. Much interest has been exhibited in the provision of this new course, which was equipped in advance of any other department in the school.

Marinette County, Wis., is erecting a building for a new agricultural high

school patterned after those already in operation in Dunn and Marathon counties.

The high school at St. Louis, Mich., has introduced a three-year agricultural course. The agricultural work begins in the second year and runs through both terms of the second and third years, the following topics being considered: The soil—origin, drainage, and capillary action; the plant—food, propagation, and diseases; orchard, garden, and field; farm animals, dairying, and gardening.

New Haven Meeting of the American Veterinary Medical Association.—The American Veterinary Medical Association held its forty-third annual meeting in Harmonie Hall, New Haven, August 21 to 24. About 150 members were present, and a still larger number of visiting veterinarians and others attended the sessions.

A special feature of the meeting was the unusual interest shown in the improvement of veterinary education in the United States by raising the standard of entrance requirements in veterinary schools, improving the curricula in these institutions, and standardizing so far as possible the veterinary degree. An association of veterinary faculties and veterinary examining boards has been formed from the members of the general association, and this branch association has undertaken seriously the work of improving veterinary education. Reports were received from men who had personally inspected all veterinary schools in the United States and Canada, and specific features of these institutions were approved or disapproved according to the manner in which they met the requirements laid down by the association.

On the whole, it appeared that there is much encouragement along this line, since definite improvement was shown in a number of educational institutions and in the work of the veterinary examining boards of the different States. The defects of the systems in vogue in different localities were thoroughly discussed and suggestions made for improvement during the coming year.

W. H. Lowe in his presidential address referred to the good showing made by the meat-inspection service in the recent agitation, and recommended that the association give all possible help to the improvement of the veterinary organization of the Army, veterinary education, and veterinary journalism in the United States.

C. J. Marshall, in his report as chairman of the committee on intelligence and education, considered particularly the educational value of veterinary hospitals. In order to make a thorough study of cases of animal diseases it is necessary to have the patients under closer observation than is possible in ordinary private practice. The reports of stock raisers on the condition of animals during treatment can not be relied upon very fully, since such men do not observe closely all the symptoms which appear during treatment.

In the reports furnished by resident State secretaries it appeared that rabies has prevailed to an unusual degree in Connecticut; hog cholera is rapidly passing under control in Kansas; a flourishing veterinary association has been established in Kentucky; vaccination against bovine tuberculosis is progressing satisfactorily in Pennsylvania; tick eradication is being pushed forward in Tennessee; Government support to the veterinary service is satisfactory in Cuba and Hawaii; milk sanitation has been put on a good basis in Massachusetts; veterinary education is improving in Illinois, but the Chicago system of milk inspection is insufficient.

P. A. Fish discussed the properties of arecolin hydrobromid. This is an alkaloid from the areca nut, and in doses of 1 to 6 grains in horses causes salivation, perspiration, or purgation. A dose of one-tenth of a grain in the eye causes contraction of the pupil. Large quantities administered hypodermically

may produce respiratory paralysis. It appears to have no vermifuge effect, but is recommended for laminitis and azoturia. One of the most marked effects of the drug is to lower the blood pressure.

V. A. Moore and W. J. Taylor discussed the agglutination method in the diagnosis of glanders. The method is considered very useful in doubtful cases. The process takes place even with dead glanders bacilli, and mallein does not interfere with the reaction. In general, a reaction is obtained in dilutions of 1:1,000-2,000, while in the case of nonglanderous serum a reaction will not take place in a dilution greater than 1:500.

G. H. Bernis reported that in a test of the agglutination method in 152 cases the results were confirmed in all except one case.

The control of glanders in the Dominion of Canada was discussed by J. G. Rutherford. When the Dominion government first took up the control of tuberculosis reacting horses were held in quarantine and subsequently tested with mallein in the hope that some of them might cease to react or become cured. This method has been abandoned, however, in favor of the one of slaughtering all glanderous horses whether showing visible symptoms of glanders or not. The reason for the change of policy lies in the fact that reacting but nonclinical cases of glanders were found to be fruitful sources of spreading contagion.

W. H. Dabrymple, in a paper on insect enemies, referred to the importance of mosquitoes, ticks, tsetse fly, and horseflies in transmitting animal and human diseases. A number of other biting insects may be concerned in the transmission of diseases and at least contribute to a considerable loss of condition in animals.

A. Loir referred to his recent experience in South Africa and elsewhere in diagnosing rabies by means of Negri's corpuscles. The author's experience indicates that wherever Negri's corpuscles are found a reliable diagnosis of rabies may be reached, but that the absence of corpuscles does not necessarily exclude the possibility of rabies being present.

A. T. Peters described a spraying method for the control of cattle mange. In Nebraska and elsewhere cattle mange was first treated by hand, after which dipping was inaugurated on a large scale in 1900. A spraying machine has now been devised which, in the author's opinion, is more effective than any dipping system. The cattle are driven through a chute where they receive the spray from all sides simultaneously. The machine can be set up anywhere on the range, and the cattle therefore do not have to be driven long distances to be treated. It will spray from 800 to 1,000 cattle per hour, and any dip can be used, although a 25 per cent mixture of crude oil and water is preferred.

R. Ebbitt gave the results of his study on tuberculosis in swine, which appears most commonly in a glandular or scrofulous form. The author has observed more tuberculosis in swine than in cattle, and believes this is not all due to the use of creamery by-products, but rather to feeding tankage. The last idea, however, was combated by a number of other members in discussion.

S. H. Ward, in a paper on Tuberculosis in Cattle, stated that mammary tuberculosis is very rare and that inhalation is not the main source of the disease. Most cases appear to be of intestinal origin. The retropharyngeal glands were found to be affected in 60 per cent of cases.

C. H. Jewell gave an account of the veterinary service in the Army. At present there are 30 veterinarians in the cavalry service and 12 in the artillery service. Some improvements are needed in the service such as would be obtained by giving the veterinarians a regular military footing and the retirement privilege. The service also needs more hospitals.

A. Peters discussed the problems of city milk supply. Statistics were given showing the amount of milk used in various cities, and attention was called to the general awakening of the public to the importance of supervision of city milk. Veterinary inspection is needed everywhere, and in all localities where it has been introduced good results have followed.

W. L. Williams described the surgery of roaring. The surgical treatment for roaring has been fairly well perfected since 1845, but the technique has been much improved recently. Different operators have different methods, such as removing the arytenoid cartilage, the vocal cords, or the proliferating tissue in this region.

T. Butler presented a brief statement of the present status of tick eradication in the South. The problem is considered a national one, and the interest and support of northern veterinarians were solicited. In North Carolina 11 counties have been freed from ticks.

S. E. Weber referred to the possible agency of insects in carrying tubercle bacilli and other pathogenic organisms. It was stated that insects may carry tubercle bacilli in human sputum, and the Psocidae are believed to be particularly concerned in this transmission.

The clinic held on the last day of the meeting was of unusual interest and included a number of cases of roaring, neurotomy, quittor, dentigerous cyst, and other cases.

The following officers were elected for the ensuing year: President, J. Law; vice-presidents, J. G. Rutherford, W. T. Monsarrat, L. A. Merillat, E. B. Ackerman, and H. Jensen; secretary, R. P. Lyman; and treasurer, G. R. White.

Miscellaneous.—Dr. H. Marshall Ward, F. R. S., professor of botany at Cambridge University, died August 26 at the age of 52 years. Dr. Ward was a well-known writer upon diseases of plants, and had given special attention to those affecting timber trees.

The death is reported of Dr. E. von Freudenreich, director of the Bacteriological Laboratory of the Swiss Agricultural Experiment Station, at Liebefeld, near Bern, and widely known for his contributions to dairy bacteriology. His death occurred August 22.

F. S. Earle, director of the Central Experiment Station of Cuba since its organization, has resigned his position.

A. J. Pieters, of the Bureau of Plant Industry of this Department, has resigned to engage in commercial seed growing in California.

J. van Leenhoff, formerly of this Department, has been appointed tobacco expert and chief of the tobacco division of the Transvaal Department of Agriculture.

It is announced that an international conference on the selection and introduction of useful plants will be held at Paris in the near future.

The Forest Service of this Department has recently established a laboratory in Boston, Massachusetts, for the purpose of making investigations and experiments in the manufacture of chemical wood pulps. The principal object of the laboratory is (1) to test the pulp-making possibilities of woods other than spruce to see if a substitute can not be found for this wood in paper making, (2) to find other fibers that may have properties peculiarly adapted to special kinds of paper making, and (3) to see if a pulp of marketable value can not be obtained from the waste material in sawmill and lumbering operations.

NOTE.—The publications of the United States Department of Agriculture, except those of the Weather Bureau, may be purchased from the Superintendent of Documents, Washington, D. C. For the publications of the Weather Bureau, requests and remittances should be directed to the Chief of the Bureau. The price of the Record is \$1 per volume, or 10 cents per number. The prices of other technical publications are given in the list above. The publications of the State experiment stations are distributed from the stations and not from the Department.

EXPERIMENT STATION RECORD.

VOL. XVIII.

OCTOBER, 1906.

No. 2.

The address of Mr. James J. Hill upon "The future of American agriculture" has attracted wide attention and comment in the public press. It was a notable address, showing thorough familiarity with the improvident and wasteful methods that have characterized much of our farming, and a full realization of impending dangers to the future well being—not of agriculture merely, but of all industry. It was a powerful appeal for a greater degree of intelligence in farming operations and for placing the art on a more enlightened and conservative basis.

Coming from a man of national reputation as a shrewd and far-seeing business manager and promoter, and presenting facts with a vividness that startles, the address commands respect and enforces thoughtful consideration. It is this, rather than the originality of the views advanced, which has served to attract public attention and lend to it an influence which the conclusions of a less prominent man would not have had.

It is a hopeful sign when a man of great business interests is able to recognize the economic value of scientific work to agriculture and to appreciate the importance of the conservative methods it has taught. When such a man is willing to pause long enough in his work of promotion and development to sound a note of warning that arouses attention from coast to coast, agricultural experimentation is conscious of having gained a strong ally and received a marked impetus. Such a champion is worth much to the cause.

Mr. Hill's intelligent appreciation of the problems of agricultural production and the teachings of scientific study and experimentation was no surprise to those who have known him. This was to be expected of a man who has taken sufficient interest in the establishment of a substation in Minnesota to give three-quarters of a section of land for it, who has lent his support to the movement for agricultural schools in that State which resulted in favorable legislative action, and who has carried thousands of farmers to the agricultural colleges and experiment stations of Minnesota and North Dakota especially, free of charge or at nominal fare, that they might see the work done there and be placed in position to profit by it.

The keynote of Mr. Hill's address was the maintenance of soil fertility as the rightful heritage of posterity. The necessity and far-reaching importance of doing this was enforced as it rarely has been before. In a striking way he showed the fundamental dependence of all industry upon the soil, the source not only of food, but of wealth to support manufactures. "All the life that exists upon this planet, all the development of man from his lowest to his highest qualities, rest as firmly and as unreservedly upon the capacities of the soil as do his feet upon the ground beneath him." All industry must stop, he explains, when the products of the soil are not forthcoming to furnish the money for the pay rolls.

He characterizes the soil as "the one unfailing national resource, . . . the sole asset that does not perish because it contains within itself, if not abused, the possibility of infinite renewal." But he points out that in utter disregard of these facts the waste of this treasure "has proceeded so far that the actual value of the soil for productive purposes has already deteriorated more than it should have done in five centuries of use." He quotes the late Professor Shaler as saying that "of all the sinful wasters of man's inheritance in the earth, and all are in this regard sinners, the very worst are the people of America," and shows that nowhere is this reckless disregard of future needs exemplified in a more marked degree than in the treatment of our soils. "There is," he says, "except in isolated and individual cases, little approaching intensive agriculture in the United States. There is only the annual skimming of the rich cream, the exhaustion of virgin fertility, the extraction from the earth by the most rapid process of its productive powers, the deterioration of life's sole maintenance. . . . Except in isolated instances, on small tracts here and there farmed by people sometimes regarded as cranks, and at some experiment stations, there is no attempt to deal with the soil scientifically, generously, or even fairly."

The effect of this depletion of fertility is illustrated by the statistics of production and the low return in money value from an acre of land. He points to sections where everything has been taken away and nothing given back, and where, owing to the wasteful methods, a condition has already resulted in which "agriculture as an independent industry, able in itself to maintain a community, does not exist." He shows that while the yield of wheat in the favored wheat-producing areas in the Northwest has fallen from an average of 25 bushels an acre to 12 or 15 bushels, the production of other countries has steadily increased and fertility been built up at the same time. "The French now draw from the soil more than five times as much wealth as they did a century and a half ago."

Some startling figures are presented to show the inadequacy of our present production in the face of a rapidly increasing population. It

is estimated that at the present rate of growth this country will have a population of 130,000,000 less than twenty years hence, and that within forty-four years we shall have to meet the wants of more than 200,000,000 people. It is stated as a mathematical fact that within twenty years, under present conditions, our wheat crop will not be sufficient for home consumption and seed, without leaving a bushel for export.

These facts were presented, not in the spirit of the pessimist, but to enforce the necessity for action which will check the present tendency and prevent further damage. Diversification in farming was urged—the practice of rotation of crops, of stock raising, and of more intensive tillage, which will make our lands more productive while it maintains their fertility; and with this done it was concluded that our possibilities would be equal to the demands. “If not another acre were to be redeemed from the wilderness,” he says, “if the soil were treated kindly and intelligently, and if industry were distributed duly, and popular attention were concentrated upon the best possible utilization of the one unfailing national resource, there would be produced all necessary food for the wants of, in round numbers, 650,000,000. But this means such study and labor to raise production to its highest terms as have entered scarcely at all as yet into the American comprehension.”

The remedy, Mr. Hill suggests, lies in agricultural experimentation and popular demonstration. “Let the zeal for discovery, for experiment, for scientific advancement that have made the last century one of multiplied wonders, focus themselves upon the problems of the oldest of sciences and arts.” Let the Government establish model farms in every rural Congressional district, “later perhaps in every county in the agricultural States,” in order to illustrate better methods of farming to maintain fertility. “Let the Department of Agriculture show exactly what can be done on a small tract of land by proper cultivation, moderate fertilizing, and due rotation of crops.”

Whether or not we agree with the exact form which this relief should take, we must agree that the remedy lies along the lines of agricultural experimentation to furnish the basis for reform, and of popular instruction and demonstration to bring the facts forcefully before the people. And all will agree with his assertion that there must be “a readjustment of national ideas such as to place agriculture and its claims to the best intelligence and the highest skill that the country affords in the very fore front.”

The problems of soil fertility are foremost at many of our experiment stations at the present time, and a considerable share of the projects planned to be investigated under the Adams fund center around this subject. The fundamental importance of the subject is

not underestimated, but the difficulties in studying so complex a question are very great.

In this connection the presidential address of Dr. E. B. Voorhees, before the American Chemical Society at the Ithaca meeting last summer,^a is timely and instructive. It deals with *Some Problems for Agricultural Chemists*, which it shows require the cooperation of other branches of science as well. It makes some specific suggestions for lines of investigation which are fundamental in character and are greatly needed at this time to answer the questions of practical men. As indicating the difference between such fundamental investigation and isolated experiments, and as showing something of the method of attack, the address is excellent.

One of the problems proposed is the ultimate effect of the continued use of commercial fertilizers. It is pointed out that in some cases a condition has resulted from using large quantities of commercial fertilizers which makes the soil less responsive or less adapted to certain crops. This effect may be assigned to various causes—chemical, physical, biological, etc.—but in the speaker's opinion we have as yet nothing definite and positive to answer. The question is a very live and important one, and grows in large measure out of the system of fertilization which has been recommended.

Another problem relates to the decline in productive capacity of soils under cultivation, especially in the richer sections—that is, the loss of fertility. This may be explained in part as due to imperfect chemical or physical or bacteriological conditions of the soil, or of all of these combined, but it is urged that we should not deal in probabilities, and we do not yet know the measure of the effect of these various factors. We must find out what the cause of the apparent exhaustion is, be able to show the farmer what his sources of loss are, and suggest a remedy.

The importance of humus in relation to fertility is another subject mentioned which needs investigation. Notwithstanding all the investigations that have been made, the speaker expressed his conviction that much remains to be learned as to the function of this constituent and the manner of the influence it exerts in maintaining and improving fertility of soils. "We are unable from our present knowledge to state whether the effect is physical, chemical, or biological, or whether it is a combined effect of each, or whether it is absolutely essential that the organic matter be present in large amounts in order that the best results may be obtained. It is a problem well worthy of the attention of our agricultural chemists, and one which must be solved if we are to give safe advice as to the cultivation of our soils."

The nitrogen question, the maintenance of the proper supply in the soil and prevention of losses, is also pointed to as one of far-

^a Published in *Science*, n. ser., 24 (1906), No. 613, pp. 385-390.

reaching importance to agriculture, and the application to this end of nitrogen assimilation from the air by certain plants. "We have many instances of attempts made to improve soils or to maintain their fertility by the introduction of leguminous crops, which have proved disastrous rather than helpful in promoting plant growth or of permanently increasing fertility in this respect. Furthermore, we have no definite knowledge as yet as to the conditions which are necessary in order that the plants shall appropriate nitrogen from the air rather than from the soil, nor have we any definite information as to how large a proportion of the nitrogen so gathered is retained in the soil for the use of cereal and other crops which depend entirely upon soil sources for their nitrogen."

The supplying of fertilizing elements other than nitrogen is also a question for the near future, in view of the present heavy demands upon the known supplies of these materials. While there is sufficient supply of these in the soil to last for certain kinds of crops for centuries, under conservative management, it is pointed out that there is a class of crops—such as vegetables, fruits, berries, etc., the demand for which is rapidly increasing—which "can not be grown to perfection and in such quantities as to meet the demands of a modern civilization without the stimulating effect of immediately available plant food." The increasing demand for these fertilizing elements, the speaker held, could not be supplied by natural means, including the use of homemade manures, and hence the source of supply of phosphate and of potash salts furnishes a broad field for study.

Another problem, economic in character, has to do with the transfer of the plant food elements from one place to another, and their loss in so far as our own country is concerned. "There is no doubt but that by careful adjustments of trade conditions it will be possible to obtain quite as much money for our surplus products as is obtained at the present time without having the practice result in so great an annual loss of our plant-food constituents."

It will be seen that in a large measure these two addresses dealt with the same great agricultural problem, but from somewhat different points of view—the one enforcing the need of checking the rapid depletion of soils in fertility, in view of the fundamental importance of the soil to all industry and the rapidly increasing population; the other by analyzing the subject and suggesting lines of research upon which to base methods for greater conservation of this fertility and increased agricultural production. In conclusion Doctor Voorhees emphasized the importance of a broad and detailed study of the whole question of soil fertility, and his belief that "there is no field of investigation more promising of fruitful results for the investigator and the country at large."

One of the greatest needs in investigation along this line is to deal with the subject in its different phases, rather than to consider it for purposes of research in extenso. Soil fertility in itself is not a project. It is a grand division of agriculture embracing a score, perhaps hundreds, of projects. And if we are to learn anything more about soil fertility than that it is the ability to produce crops, and more about its maintenance than the calculated amounts of nutrients removed and the fertilizing constituents needed to make good this draft, we must separate this great subject into its different phases and prosecute the individual research along narrow lines.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY.

On the determination of water-soluble and total phosphoric acid in superphosphates, K. ROHM (*Chem. Ztg.*, 30 (1906), No. 44, pp. 542, 543; *abs. in Analyst*, 31 (1906), No. 365, p. 275; *Jour. Chem. Soc. [London]*, 90 (1906), No. 525, 11, p. 490; *Chem. Centbl.*, 1906, 11, No. 2, p. 163).—“Water-soluble phosphoric acid.—A number of determinations were made on 3 samples to compare the method in which the sample is digested with water for 2 hours, with occasional shaking, with that in which it is agitated continuously with water for 30 minutes in a shaking machine, different speeds being also tested. The most constant results are given by the latter method, the speed being about 30 to 40 rotations per minute, but digesting the sample without any shaking at all gave results only about 0.2 per cent too low (with 19 per cent of water-soluble P_2O_5). The sample used should pass through a 2 mm. mesh sieve.

“Total phosphoric acid.—Extraction with nitric acid, with a mixture of nitric and sulphuric acids, and with aqua regia, gave practically identical results. Extraction with hydrochloric acid, which is never used in practice, gave results about 0.2 per cent too low. The magnesia precipitate should be allowed to stand 24 hours before filtering, or else mechanically stirred for 30 minutes. On allowing it to stand for only 2 hours, an error of up to 0.22 per cent of P_2O_5 was found in a number of analyses.”

Investigations on the causes of error in the application of the citromechanical method to the determination of phosphoric acid in natural phosphates and phosphatic slags, E. GUERRY and E. TOUSSAINT (*Bul. Agr. [Brussels]*, 22 (1906), No. 3, pp. 315-349; *Bul. Soc. Chim. Belg.*, 20 (1906), No. 5-6, pp. 167-203).—Studies are reported which lead to the conclusion that the errors referred to are due to the presence of fluo-silicates and to a deficiency of iron salts as compared with silica in solution. The author proposes to eliminate the errors due to these causes by removing the fluorin by treatment with sulphuric acid and by adding iron salts before precipitation according to the following method:

To 2.5 gm. of the material in a 250 cc. Jena glass flask add 10 cc. of concentrated sulphuric acid and heat over wire gauze until acid fumes begin to appear, allow to cool, adding water carefully until the volume has reached about 100 cc., then add 25 cc. of aqua regia and boil for 10 minutes on a sand bath, cool, make the volume to 250 cc., and filter. To 25 cc. of the filtrate add in the case of natural phosphates 5 to 10 cc. of a 2 per cent solution of ferric chlorid, neutralize partially with ammonia, cool if necessary, and add 30 cc. of citrate solution with 15 cc. of ammonia and 35 cc. of magnesia mixture, shake for $\frac{1}{2}$ hour, filter after allowing to stand for 1 hour, wash, ignite, and weigh.

The author uses either Peterman's alkaline citrate or a solution containing 500 gm. of citric acid neutralized with a slight excess of ammonia and made to

a volume of 2 liters. In case of the latter solution 40 cc., corresponding to 10 gm. of citric acid, is used.

The separation of silicic acid in the determination of citric-acid soluble phosphoric acid, J. HASENBÄUMER (*Chem. Ztg.*, 30 (1906), No. 53, pp. 665, 666; *abs. in Chem. Centbl.*, 1906, II, No. 6, p. 536).—Investigations with a number of different kinds of Thomas slag are reported which show that the higher results obtained when silicic acid is not previously removed from the solution are not due to the presence of this substance in the precipitate, and indicate that the discrepancy may be due either to the carrying down of a certain amount of phosphoric acid in the gelatinous silicic acid when this is removed before precipitation or to the fact that the precipitate obtained after removal of the silicic acid is different in composition from that produced before such removal.

The use of compressed air in analysis of superphosphate, G. SCHLIEBS (*Chem. Ztg.*, 30 (1906), No. 47, p. 584).—Good results are reported in the substitution of agitation by means of a stream of compressed air in place of mechanical agitation.

The determination of potash in potash salts and mixed fertilizers by the Neubauer modification of the Finkener method, M. KLING and O. ENGELS (*Ztschr. Analyt. Chem.*, 45 (1906), No. 5-6, pp. 315-332; *abs. in Analyst.*, 31 (1906), No. 365, pp. 273, 274; *Chem. Centbl.*, 1906, II, No. 4, p. 360).—The authors have used the following modification of the Finkener-Neubauer method with satisfactory results:

Dissolve 10 gm. of the potash salt in 500 cc. of water, and to 25 cc. of this solution, corresponding to 0.5 gm., add a few drops of hydrochloric acid, the necessary platinum chlorid, and evaporate to dryness in a porcelain dish. Take up with water and alcohol as in Neubauer's method, collect on a Neubauer-Gooch crucible, wash with alcohol, and dry by placing the crucible on a moderately hot metal plate.

Reduce the platinum salt in a current of coal gas, heating for the first 10 minutes over a very low flame, and finally at a faint red heat for 20 minutes. When reduction is complete heat the crucible for 2 minutes over the naked flame of a Teclu burner, wash the contents of the crucible about 15 times with hot water and 2 or 3 times with cold 15 per cent hydrochloric acid, immerse the crucible to about three-quarters of its height in nitric acid of the same strength in a porcelain dish, cover the dish with a clock-glass, heat for about 30 minutes on the boiling water-bath and allow to cool. Finally wash the platinum in the crucible with hot water and alcohol, ignite, and weigh.

In case of mixed fertilizers, shake 20 gm. of the sample with 800 cc. of water for 30 minutes in a liter flask, make up to the mark, and filter. To 100 cc. of the filtrate, corresponding to 2 gm., add ammonia and ammonium carbonate in a 200 cc. flask, make the volume to 200 cc., and filter and evaporate 50 cc., corresponding to $\frac{1}{2}$ gm. of material to dryness in a platinum dish. Dry the residue, drive off ammonium salts, and ignite to fusion, taking up the fused residue with hot water and a little hydrochloric acid. Filter if there is an insoluble residue. Add platinum chlorid solution (2 cc. of a 10 per cent solution is usually sufficient), evaporate to dryness, and determine potash as described above.

The accuracy of the method was tested by a number of determinations and it was shown that the presence of phosphates does not interfere with the determination. A table for calculating the amount of potash from the weight of platinum obtained from 0.5 gm. of substance (factor=0.48108) is given.

On the determination of potash by means of platinum hydrochlorid in the presence of sulphates of the alkalis and alkaline earths, K. REGEL (*Chem.*

Ztg., 30 (1906), No. 55, pp. 684, 685; *abs. in Chem. Centbl.*, 1906, II, No. 6, p. 558; *Analyst*, 31 (1906), No. 366, p. 813).—The author employs a modification of Fresenius's so-called short method, in which the potassium platinum chlorid is reduced by means of nascent hydrogen and the separated platinum is weighed.

In the method proposed the solution of the potash salt is evaporated directly with platinum chlorid without previous precipitation with barium chlorid. The potassium platinum chlorid obtained is treated as directed by Fresenius, being washed from the filter into a small beaker and the particles remaining on the filter dissolved in hot water. An excess of magnesium powder is added and the solution gently heated. The precipitate of platinum is collected on a filter and any excess of magnesium is removed by washing with dilute hydrochloric acid. The platinum is then dried, ignited, and weighed.

If magnesium and calcium sulphate are present these are removed by washing with 5 per cent nitric acid. It is stated that in a series of tests of the method results were obtained which agreed well with those yielded by the Fresenius and Finkener-Neubauer methods.

A few observations on elementary analytical determination of ash, F. VON KONEK (*Chem. Ztg.*, 30 (1906), No. 46, pp. 567, 568; *abs. in Chem. Centbl.*, 1906, II, No. 7, p. 631).—By combining ash determination and analytical combustion in one operation the ash content is always higher than by ordinary incineration. By heating the ash obtained in the combustion in the air the weight is reduced to that obtained in ordinary determinations. The difference is said to be due to incomplete dissociation of carbonates of alkalis and alkaline earths, to the variation in volatility of the alkaline salts, and to various minor causes which are enumerated.

Estimation of carbon in soils and kindred substances, A. D. HALL, N. H. J. MILLER, and N. MARMU (*Jour. Chem. Soc. [London]*, 89 (1906), No. 522, pp. 595-597, *fig. 1*).—The authors tested Wolff's method of determining organic carbon by oxidizing with a mixture of chromic and sulphuric acids, and found that while this method in its original form gave results which were much too low, by the addition of a short tube containing red-hot copper oxid to complete the combustion the whole of the carbon in the soil could be obtained as carbon dioxide. The carbon dioxide evolved is absorbed in dilute caustic alkali in a Keiset tower and determined by double titration with phenolphthalein and methyl orange, as suggested by Hart.

A method of determining hydrogen peroxid and ferrous salts and other reducing agents, W. E. MATHEWSON and J. W. CALVIN (*Amer. Chem. Jour.*, 36 (1906), No. 2, pp. 113-117).—The yellow compound formed by the action of hydrogen peroxid upon soluble titanium compounds is instantly decomposed by reducing agents. The authors have utilized this fact in devising a method for determining reducing agents by titrating against a standard solution of hydrogen peroxid and vice versa, a titanium salt being used as an indicator. The results reported in this paper were obtained with ferrous ammonium sulphate and sodium nitrite.

On the Polenske method for the detection of cocoanut oil in butter, S. RIDEAL and H. G. HARRISON (*Analyst*, 31 (1906), No. 365, pp. 254-260, *fig. 1*).—This method (*E. S. R.*, 15, p. 850) depends upon the relation of the insoluble to the soluble volatile fatty acids, which the authors do not find to be as constant in pure English butters as was found by Polenske.

For pure butter obtained from different localities in England during June and July the Polenske numbers varied from 1.6 to 2.15. Samples taken fortnightly from the same dairy for nearly a year showed variations from 1.2 to 2.75. The average Reichert-Meissl and Polenske numbers for the pure English butters

were, respectively, as follows: Two samples 27.88 and 1.33, 2 samples 28.70 and 1.53, 7 samples 29.36 and 1.77, 8 samples 30.44 and 2, 7 samples 31.52 and 2.10, 3 samples 32.43 and 2.37, and 1 sample 34.55 and 2.15.

The authors find, however, that when coconut oil is added to a pure butter fat the relative increase in the insoluble acids agrees practically with the results obtained by Polenske. An increase of 1 in the Polenske number over that of a genuine butter having the same Reichert-Meißl number indicates the addition of 10 per cent coconut oil, the minimum quantity that can be detected by this method.

In no case did the samples of margarin examined give a higher Polenske number than 1. Cheese fats showed the same ratio of insoluble to soluble fatty acids as in the case of butter.

The determination of fat in milk powder and cream cheese, H. HAUPT (*Ztschr. Untersuch. Nahr. u. Genussmitl.*, 12 (1906), No. 4, pp. 217-221).—The author favors the Gottlieb-Röse method. In 4 milk powders the fat content as determined by this method was, respectively, 17.33, 17.86, 28.55, and 28.84 per cent and by ether extraction 17.16, 17.40, 28.48, and 28.99 per cent. A sample of Parmesan cheese showed a fat content of 26.85 per cent by the Gottlieb-Röse method and 26.28 per cent by ether extraction for 10 hours. Corresponding results were obtained with Emmenthal, Edam, Gorgonzola, and Camembert cheese.

Proceedings of the twenty-second annual convention of the Association of Official Agricultural Chemists, held at Washington, D. C., November 16, 17, and 18, 1905, edited by H. W. WILEY (*U. S. Dept. Agr., Bur. Chem. Bul.* 99, pp. 211, figs. 2).—This is the official report of the proceedings of the convention. A summarized account of the meeting has been given (*E. S. R.*, 17, p. 423), and a circular of the Bureau containing extracts from the proceedings noted (*E. S. R.*, 17, p. 834).

Cooperative work on fats and oils, Association of Official Agricultural Chemists, 1906, L. M. TOLMAN (*U. S. Dept. Agr., Bur. Chem. Circ.* 27, pp. 6).—This contains the provisional method for the titer test adopted by the association in 1905 and a differentiation of the "cold test" and the "cloud test" as a basis for further cooperative work.

Provisional methods for the determination of food preservatives as authorized by the Association of Official Agricultural Chemists, 1905 (*U. S. Dept. Agr., Bur. Chem. Circ.* 28, pp. 13, fig. 1).—This circular contains the changes and additions to the provisional methods for the analysis of foods published as Bulletin 65 of the Bureau so far as they relate to preservatives.

Changes in provisional methods for the analysis of foods and additions thereto, from 1902 to 1905 (*U. S. Dept. Agr., Bur. Chem. Circ.* 29, pp. 20).—Owing to the impracticability of revising Bulletin 65 of the Bureau it has been thought best to compile the additions to and changes in the methods given in that bulletin which have been authorized by the Association of Official Agricultural Chemists and to suggest at the next convention a plan for the revision of all the methods.

Changes in official methods of analysis and additions thereto, 1899 to 1905 (*U. S. Dept. Agr., Bur. Chem. Circ.* 30, pp. 28).—It has been found impracticable to incorporate the changes and additions authorized by the Association of Official Agricultural Chemists to the official methods of the association as published in Bulletin 46 of the Bureau of Chemistry, so this and the three circulars noted above, giving a compilation of the authorized changes and additions, have been issued for the purpose of presenting the present status of the methods in order that the subject of revision may be acted upon by the association at its next convention.

METEOROLOGY—WATER.

Report of the Chief of the Weather Bureau, 1904-5 (*U. S. Dept. Agr., Weather Bur. Rpt. 1904-5, pp. XXIV+384*).—Part 1 of this report contains a review of the last 10 years' work of the Bureau and an account of the work of the year (*E. S. R., 17, p. 734*); part 2, a list of observing stations and changes therein during 1904, and twice-daily observations for 30 selected stations, 1904; part 3, monthly and annual meteorological summaries for 180 stations; part 4, monthly and annual means and extremes of temperature and dates of first and last killing frosts, 1904; part 5, monthly and annual precipitation, 1904; and part 6, miscellaneous meteorological tables and reports.

Monthly Weather Review (*Mo. Weather Rev., 34 (1906), Nos. 3, pp. 109-156, figs. 13, charts 7; 4, pp. 157-200, pls. 2, charts 7*).—In addition to the usual reports on forecasts, warnings, weather and crop conditions, meteorological tables and charts for the months of March and April, 1906, recent papers bearing on meteorology, recent additions to the Weather Bureau library, etc., these numbers contain the following articles and notes:

No. 3.—Structure of Hailstones, by E. S. Webster; Studies on the Thermodynamics of the Atmosphere—III, Application of the Thermodynamic Formule to the Nonadiabatic Atmosphere (illus.), by F. H. Bigelow; German Aerial Research Station: A New Departure in Forecasting; Atmospheric Effects in Astronomical Observations; The Eighth International Geographic Congress; The Legitimate Line of Duty; The Tornado at Meridian, Miss., March 2, 1906 (illus.), by L. A. Denson; The Opportunities of the Weather Service; Drought and Atmospheric Electricity; Severe Hailstorm at Pensacola, Fla., by W. F. Reed, jr.; A Peculiar Temperature Fluctuation (illus.), by W. Upton; Halos of March 1-4, 1906 (illus.); Weather Bureau Men as Educators; Kite Flight of April 5, 1906, at Mount Weather Observatory (illus.), by O. L. Fassig; Where are the Old Records of Haiti; The Zodiacal Light (illus.), by M. Hall; and The Zodiacal Light—Is It Meteorological or Astronomical.

No. 4.—Note on Evaporimeter, by B. F. E. Keeling; The Nephological Review; Storm and Hurricane Insurance in the West Indies; Cloud Banners; The Indexing of Marine Reports; The Publication of the Chicago Memoirs; The Warmth of December, 1905; Style of Meteorological Publications; Cosmic Relations of the Atmosphere; The Province of the Monthly Weather Review; Diurnal Variation of the Barometer; Influence of the Ocean on Continental Precipitation; Pressure and Rainfall over the Indian Monsoon Area; Vincent's Bibliography of Treatises on Meteorology; Meteorology in Egypt; The Colors of Dust-haze; Can We Argue from the Climate Back to the Orography? Krakatoa Dust *versus* Krakatoa Vapor; The Convection Theory of Whirlwinds; A Method of Predicting the Movement of Tropical Cyclones, by M. Hall; On the Conditions Determining the Formation of Cloud-spheres and Photospheres, by A. W. Clayden; Theory of the Rainbow, by W. LeC. Stevens; Weather Bureau Men as Educators; and Mr. R. F. de Grain.

Meteorological observations, J. E. OSTRANDER and T. A. BARRY (*Massachusetts Sta. Met. Buls., 209, 210, pp. 4 each*).—Summaries of observations at Amherst, Mass., on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during May and June, 1906. The data are briefly discussed in a general note on the weather of each month.

Meteorological observations, W. T. ELLIS, W. T. MACOUN, R. ROBERTSON, W. S. BLAIR, S. A. BEDFORD, A. MACKAY, and T. A. SHARPE (*Canada Expt. Farms Rpts., 1905, pp. 28, 91, 263, 301, 321, 356, 357, 400, 401, 438*).—Summaries are given of observations on temperature, precipitation, etc., during 1905 at

Central Experimental Farm, Ottawa; Nappan, Nova Scotia; Brandon, Manitoba; Indian Head, Northwest Territories; and Agassiz, British Columbia.

Meteorological chart of the Great Lakes, A. J. HENRY and N. B. CONGER (*U. S. Dept. Agr., Weather Bur., Met. Chart Great Lakes, 1906, No. 1, pp. 20, pl. 1*).—This is a summary of observations on the meteorological conditions of the winter of 1905-6 in the lake region, with notes on ice on the Great Lakes winter of 1905-6, opening of navigation for the season of 1906, and display of storm warnings on the Great Lakes. Lists of stations and location of flagstaves and steel towers, and Canadian Great Lakes storm-warning stations are also given.

Well waters from farm homesteads, F. T. SHUTT (*Canada Expt. Farms Rpts. 1905, pp. 154-157*).—Of the 83 samples of water of which analyses are given "22 were reported as safe and wholesome, 38 seriously polluted, 12 suspicious and probably unsafe for drinking purposes, and 11 saline in character."

Fluctuations of the water level in wells, with special reference to Long Island, New York, A. C. VEATCH (*U. S. Geol. Survey, Water-Supply and Irrig. Paper No. 155, pp. 83, pls. 9, figs. 17*).—This bulletin contains a report of observations made on the fluctuation of the water level in wells, both with direct reading and self-recording gages, in connection with an investigation of the geology of Long Island by the Geological Survey in the summer of 1903, and also a general discussion of the fluctuation of water in wells.

Some of the results of this study may be briefly summarized as follows:

"(1) The most important and characteristic of the natural ground-water fluctuations is the regular annual period. This is a relatively uniform curve, with a single maximum and minimum, on which the fluctuations of shorter periods, as a rule, form but minor irregularities. This curve does not generally resemble the rainfall curve. Were the rainfall uniform throughout the year, the ground water would still show a regular yearly period and the maximum would occur early in the year in the North Temperate Zone. The effect of irregularities in the rainfall is to move the time of occurrence of this maximum either forward or back.

"(2) The water from single showers is generally delivered gradually to the ground-water table and, even where noticeable fluctuations are produced, these do not commonly make important irregularities in the regular annual ground-water curve.

"(3) Single showers may, by transmitted pressure through the soil air, produce instantaneous and noticeable rises in the water in wells and notably increase the stream discharge without contributing either to the ground water or directly to the surface flow.

"(4) The amount contributed to the ground water can not be satisfactorily estimated by the rise and fall of the water in wells, because the same amount of rainfall under the same geologic and climatic conditions, in beds of the same porosity, will produce fluctuations of very different values. Near the ground-water outlet the total yearly range may be but a few inches, while near the ground-water divide it may be 50 or 100 ft. When an attempt is made to calculate the amount of water received from single rains, the results are not reliable, because in the cases which are usually taken, such as sharp, quick rises, it is impossible to tell how much of the rise is due to transmitted pressure and how much to direct infiltration.

"(5) Because of the increase in stream flow due (1) to transmitted pressure from rains, (2) to changes in barometric pressure, and (3) to increase in area of ground-water discharge, with the elevation of the ground-water table, it is not possible to correctly separate the quantity of water in the stream discharge

contributed by spring flow from that contributed by direct surface run-off. There are many reasons for believing that in humid regions 'flood flows' contain large percentages of ground water.

"(6) Tidal fluctuations in wells are very often produced by a plastic deformation due to the loading of the tides, and the occurrence of such fluctuations in wells does not in itself indicate a connection between the water-bearing strata and the sea.

"(7) Temperature changes may produce marked fluctuations (1) by changes in capillary attraction—such fluctuations are perceptible only at the surface of the zone of complete saturation, are not transmitted to deeper levels, and vary directly with the temperature; (2) by changes in viscosity or rate of flow—fluctuations due to this cause vary inversely with the temperature, and show in deep wells by transmitted pressure."

The geology and water resources of the eastern portion of the Panhandle of Texas, C. N. GOULD (*U. S. Geol. Survey, Water-Supply and Irrig. Paper No. 154, pp. 64, pls. 15, figs. 4*).—This report summarizes field observations during 1903 and 1904 on topography, geology, water resources (underground, springs, streams, also drainage and irrigation) in general and by counties for an area of approximately 10,800 square miles, lying in the northeastern part of the Texas Panhandle, and including the counties of Lipscomb, Ochiltree, Hansford, Hutchinson, Roberts, Hemphill, Wheeler, Gray, Carson, Armstrong, Donley, and Collingsworth, each of which is approximately 30 miles square.

As regards the future of irrigation in the region the report says: "Taking into account the local facts it seems very doubtful if there will ever be any extensive irrigation in the region under discussion. The supply of water is not sufficient for this purpose except along the larger streams, where the conditions are such that dams can not be constructed. Small streams, springs, artificial ponds, and wells supply water for limited irrigation, sufficient often to raise vegetables and fruit for a family, but not more. As time goes on and the region is more thickly settled, these small plants will increase in number.

"There is little to warrant the hope that the water supply in the Panhandle will ever increase, and unless some more efficient means than the ordinary wind-mill be secured to lift the water from deep wells to the surface it is extremely improbable that anything like extensive works can ever be installed. On the other hand, it is obvious that only a very small part of the available water is now being utilized. It is possible that the future will witness in this region thousands of small pumping plants, each capable of supplying sufficient water to irrigate a garden and an orchard."

Preliminary report on the geology and underground waters of the Roswell artesian area, New Mexico, C. A. FISHER (*U. S. Geol. Survey, Water-Supply and Irrig. Paper No. 158, pp. 29, pls. 9*).—The area to which this report relates is located in southeastern New Mexico. It comprises about 1,800 square miles lying along Pecos River and extending from a point 5 miles north of Roswell to below the mouth of Seven Rivers.

In addition to the discussion of the artesian waters, the report includes a brief description of the geology of the sedimentary rocks, their structure, and their relation to the underground waters. The area of flowing wells is indicated and records of representative wells are given, which are intended to illustrate the character and succession of the water-bearing beds. Information respecting surface waters available for domestic and irrigation purposes and a brief description of the climatic and agricultural features of the region are also given.

"The climate of the Roswell basin does not differ materially in the prevailing aridity from that of the remainder of southern and eastern New Mexico. The

temperature of the region is high, with a low relative humidity. The summers are usually long and hot and the winters mild and pleasant. The maximum temperature is 110° and the minimum seldom falls far below zero. . . . The average annual precipitation at Roswell is 16.6 in. The greater part of this amount falls during the months of June and July in frequent showers, which, although often violent, are generally local and of short duration. Only a small percentage of the annual precipitation falls as snow. . . .

"The general aridity of the climate renders farming without irrigation impracticable except in a few low-lying areas adjacent to Pecos River. In consequence agriculture is restricted to those portions of the valley where water can be obtained from some of the various canals or from artesian wells. The cultivated portions of the basin at present comprise about one-eighth of the total area included in this report, the remainder being utilized for pasturage of cattle—an industry to which the higher lands are well adapted. . . .

"It is believed that there is no cause for fear that the water supply throughout the northern part of the Roswell basin will give out or become inadequate for all requirements under proper economy of practice. In the region of Artesia and McMillan not enough wells have been sunk to indicate the amount that the water-bearing beds may be expected to yield. There is pressing need for greater economy on the part of the users of well water throughout the Roswell basin."

SOILS—FERTILIZERS.

Soils, A. M. PETER and S. D. AVERITT (*Kentucky Sta. Bul. No. 126, pp. 63-126*).—This bulletin discusses methods and uses of soil analysis, reports analyses of 127 samples of soils from different parts of Kentucky, and gives the results of a comparison of 3 methods of determining humus in soils and a study of the causes of error in determinations of this substance by the method of the Association of Official Agricultural Chemists. The unsatisfactory character of methods of soil analysis for practical purposes is pointed out, but the uses which can be made of results obtained by these methods are indicated.

Results are reported which indicate that the official method for humus in soils gives results which are much too high. The author proposes to approximately eliminate the error by "deducting from the apparent weight of humus 10 per cent of the weight of the residue remaining after burning off the humus."

The determination of humus in portions of the humus solution corresponding to 1 gm. of soil by boiling with potassium permanganate solution (3 gm. of salt to 1 liter of water) gave results which agreed fairly well with the determinations by the official method corrected as described. An attempt to use a colorimetric method with the nitric-acid solution of the residue obtained by evaporating the humus solution to dryness did not give satisfactory results.

The chemical investigation of Tennessee soils, C. A. MOGERS (*Bien. Rpt. Tenn. Dept. Agr., 1903-4, pp. 147-154*).—This paper discusses briefly what constitutes fertile soil, the importance of the mineral constituents of plant food and the best proportion of these constituents in soils, and the need and value of chemical investigation of the soils of Tennessee.

Mechanical analysis of soils (*Jour. Agr. Sci., 1 (1906), No. 4, pp. 470-474*).—The method adopted by the chemical committee of the Agricultural Education Association is described and the general principles of the method are discussed. The method is as follows:

"(1) Ten gm. of the air-dry earth which have passed a 3 mm. sieve are weighed out into a porcelain basin and worked up with 100 cc. of fifth-normal hydrochloric acid, the acid being renewed if much carbonate of lime is present. After

standing in contact with the acid for 1 hour the whole is thrown upon a dried, tared filter, and washed until free of acid. The filter and its contents are dried and weighed. The loss represents hygroscopic moisture and material dissolved by the acid.

"(2) The soil is now washed off the filter with dilute ammoniacal water onto a small sieve of 100 meshes to the linear inch, the portion passing through being collected in a beaker marked at 10, 8.5, and 7.5 cm., respectively, from the bottom. The portion which remains upon the sieve is dried and weighed. It is then divided into 'fine gravel' and 'coarse sand,' by means of a sieve with round holes of 1 mm. diameter. The portion which does not pass this sieve is the 'fine gravel.' This should be dried and weighed. The difference gives the 'coarse sand.' If required, both these fractions can also be weighed after ignition.

"(3) The portion which passed the sieve of 100 meshes per linear inch is well worked up with a rubber pestle, and the beaker filled to the 8.5 cm. mark and allowed to stand 24 hours. The ammoniacal liquid which contains the 'clay' is then decanted off into a Winchester quart. This operation is repeated as long as any matter remains in suspension for 24 hours. The liquid containing the 'clay' is either evaporated in bulk, or measured and, after being well shaken, an aliquot portion taken and evaporated. In either case the dried residue consists of 'clay' and 'soluble humus.' After ignition the residue gives the 'clay,' and the loss on ignition the 'soluble humus.'

"(4) The sediment from which the 'clay' has been removed is worked up as before in the beaker, which is filled to the 10 cm. mark and allowed to stand for 100 seconds. The operation is repeated till the 'fine sand' settled in 100 seconds is clean, when it is collected, dried, and weighed.

"(5) The turbid liquid poured off from the 'fine sand' is collected in a Winchester quart, or other suitable vessel, allowed to settle, and the clear liquid siphoned or decanted off. The sediment is then washed into the marked beaker and made up to the 7.5 cm. mark. After stirring, it is allowed to settle for 12½ minutes, and the liquid decanted off. The operation is then repeated as before till all the sediment sinks in 12½ minutes, leaving the liquid quite clear. The sediment obtained is the 'silt,' which is dried and weighed as usual. The liquid contains the 'fine silt' which, when it has settled down, can be separated by decanting off the clear liquid, and dried and weighed.

"(6) Determinations are made of the 'moisture' and 'loss on ignition' of another 10 gm. of the air-dry earth. The sum of the weights of the fractions after ignition plus loss on ignition plus moisture plus material dissolved in weak acid should approximate to 10 gm.

"(7) It is advisable to make a determination of the 'fine gravel' in a portion of 50 gm. of the air-dry earth. The soil should be treated with acid, as in 1, and after that is removed by decantation may be at once treated with dilute ammonia and washed on the sieve with 1 mm. round holes. The 'fine gravel' left on the sieve is then dried and weighed, and the percentage found should agree with that found in 2. If it does not the result now found should be taken as the true one."

Agricultural reconnaissance of the Uinta Indian Reservation, W. W. McLAUGHLIN (*Utah Sta. Bul.* 93, pp. 23).—The area covered by the reconnaissance reported in this bulletin includes approximately 650,000 acres of agricultural land situated in the Uinta Basin about 105 miles east of Heber and 90 miles northeast of Price, Utah. The general conditions are described and data are given relating to climate, water supply, and soils.

It is stated that the soils of the upper part of the benches are more desirable than those of the river bottoms, which frequently contain injurious amounts of

alkali. The upper lands require more frequent and larger applications of irrigation water than the lower lands. The water supply is sufficient for all tillable lands. The climate is equable during the greater part of the year but variable in spring and fall, although there is no extreme weather and winter grazing of stock is practicable. There is some danger from frost on the upper lands. Arid or dry farming will probably not be successful on account of the very low precipitation, varying from 6 to 14½ in. at different places in the reservation for the whole year and from 1.23 to 2.95 in. for the 3 months June to August.

The changes in cultivated soils, A. MERCIER (*Bul. Soc. Chim. Belg.*, 19 (1906), No. 8-9, p. 267; *abs. in Rev. Gén. Agron.*, n. ser., 1 (1906), No. 2, pp. 56, 57).—The author concludes from his studies that digestion with hydrochloric acid of 1.18 sp. gr. does not furnish any information of practical value as to the fertility of the soil. In comparative tests of normal and tenth-normal hydrochloric acid for this purpose the conclusion was reached that the normal acid is the strongest which should be used for studies of this kind.

The author concludes that all of the fertilizing material assimilable by plants is removed in the first half liter of solution with acid of this strength when 250 gm. of soil is used for extraction. The material removed by further treatment is merely an indication of the changes in the soil. The apparatus used in the extraction with acid is described.

The amount and composition of the drainage through unmanured and uncropped land, Barnfield, Rothamsted, N. H. J. MILLER (*Jour. Agr. Sci.*, 1 (1906), No. 4, pp. 377-399, figs. 4).—In this article a brief account is given of the Rothamsted drain gages and the results obtained with them since their establishment in 1870 are summarized. There are 3 of these drain gages 0.001 acre in area, extending to depths of 20, 40, and 60 in., respectively.

The annual averages for the 35 years, 1870 to 1905, were as follows: Rainfall 28.97 in.; drainage—20-in. gage 13.84 in., 40-in. gage 14.61 in., 60-in. gage 13.65 in.; drainage per cent of rain—20-in. gage 47.8, 40-in. gage 50.4, 60-in. gage 47.1; evaporation—20-in. gage 15.13 in., 40-in. gage 14.36 in., 60-in. gage 15.32 in.

"The rain supplies annually to the soil about 5 lbs. of nitrogen. Of this amount about 4 lbs. represent nitrates and ammonia which would be rapidly nitrified in the soil, and the rest, about 1 lb., represents organic compounds which may be either more or less readily nitrified than the organic nitrogen of the soil. In any case the total amount is very small as compared with the amounts found in the drainage through the soil of the gages.

"During the last 28 years the average loss of nitrogen in the gages has been 31.4 lbs. per acre per annum. The annual losses vary from year to year considerably, partly owing to differences in the rainfall and partly to the distribution of the rain. There is, in addition . . . a slight tendency for the nitrates to decrease, but this only manifests itself when successive averages of several years are compared. The yearly amounts of nitrogen in the drainage of the 60-in. gage have varied from 61 to 15 lbs. with the highest recorded rainfall in 1878-9 (41.05 in.) and the lowest rainfall in 1897-8 (19.51 in.). Both years were preceded by years of high rainfall. In 1898-9 when the rainfall was, for a second year, unusually low, the 60-in. gage lost nearly 31 lbs. of nitrogen; and in 1899-1900 nearly 28 lbs. The very low results of 1897-8 are partly due to the complete washing out to which the gages were subjected the year before, when the 60-in. gage lost 41.4 lbs. of nitrogen. It is probable, however, that the 19 years between the maximum and minimum losses have helped to increase the difference."

The average annual amounts of chlorine found in the drainage water during 28 years of observation were as follows: In the drainage water of the 20-in.

gage 14.84 lbs. per acre, of the 40-in. gage 15.89 lbs., of the 60-in. gage 14.64 lbs. For the 28 years there has apparently been a gain of 8.68 lbs. per acre for the 20-in. gage, a loss of 20.72 lbs. for the 40-in. gage, and a gain of 14.28 lbs. for the 60-in. gage.

A list of 10 references to articles relating to this subject is given.

The relation between lime content of soils and plants, A. KADGIEN (*Fühling's Landw. Ztg.*, 55 (1906), No. 9, pp. 310-316).—The lime content of a large number of Prussian soils is compared with that of various crops grown on the soils. In the opinion of the author so many conditions influence the lime content of the plant that this can not be taken as a reliable index of the lime content of the soil. The advantages of liming, particularly when other manures are liberally used, are discussed.

On the lime factor for flax and spinach, S. NAMIKAWA (*Bul. Col. Agr., Tokyo Imp. Univ.*, 7 (1906), No. 1, pp. 57-60, fig. 1).—Pot experiments are reported which indicate that a lime-magnesia ratio in the soil of 1:1 is the most favorable for the growth of these crops.

Some analyses of natural humus compounds, E. MICHELET and J. SEBELIEN (*Chem. Ztg.*, 30 (1906), No. 31, pp. 356-358).—Analyses of typical samples of humus from 10 different sources, leaf mold, peat, soils, etc., are reported in full, showing wide variations in the composition of the humus from the different sources. Further studies of the behavior of the humus when treated with alkaline solvents, etc., are contemplated.

The control of soil moisture in orchard soils, F. T. SHUTT (*Canada Expt. Farms Rpts.*, 1905, pp. 133-137).—In continuation of previous work (E. S. R., 17, p. 119) two series of experiments, each comprising 3 plats, were instituted at the experimental farms, Ottawa, in 1905 (1) to ascertain the moisture content of soil under a thick mulch of straw as compared with that of a soil constantly cultivated and uncultivated soil; and (2) to learn the relative moisture content of soils under hairy vetch, tares, and constant cultivation.

A series of experiments were also conducted on the experimental farm, Nappan, N. S., on 6 plats "to contrast throughout the season the moisture content of soil (1) bearing an oat crop; (2) carrying a second season's growth of clover (with timothy) and harvested; (3) similar to 2, but with the growth cut from time to time and used as a mulch; (4) cultivated till June 15, then sown with crimson clover; (5) cultivated till July 20, then sown with crimson clover; (6) cultivated until July 20, then left undisturbed."

On account of the ample and well-distributed rainfall at Ottawa the differences in moisture content under the different methods of treatment were not very large. In the experiments at Nappan, however, where the rainfall was deficient, the beneficial effect of cultivation in conserving soil moisture was very strikingly demonstrated.

The variation of land and water temperatures, W. F. COOPER (*Rpt. Mich. Acad. Sci.*, 7 (1905), pp. 40-43).—This paper reports the results of a series of observations on land and water temperatures on the west side of Saginaw Bay and east of Tobico Bay, northwest of Bay City. These show the average water temperature during the period of observation (August, 1904) to be 72.11°, that of the land 72.38°.

Calcium sulphate in aqueous solutions: A contribution to the study of alkali deposits, F. K. CAMERON and J. M. BELL (*U. S. Dept. Agr., Bur. Soils Bul.*, 33, pp. 71, figs. 11).—"The purpose of this bulletin is to bring together and arrange in a logical sequence the results of the numerous investigations which have been made on the relation of calcium sulphate to aqueous solutions. Experimental methods and details are either omitted or, if of unusual interest, are described but briefly, since the numerous references to the literature which

are given will make them available to anyone who may be interested. In like manner practical applications of the results are merely indicated, as their discussion can be more profitably given elsewhere than in this necessarily technical description of a chemical problem."

The bulletin deals with the transformations of the different modifications of calcium sulphate: the occurrence of calcium sulphate in nature; solubility of the salt in water and in aqueous solutions of calcium sulphate and other calcium salts, of electrolytes not containing a common ion, and of nonelectrolytes, and calcium sulphate in salt deposits in alkali regions. It is presented as "a chapter in the larger study of the chemistry of alkali," developing the theories advanced in Bulletin 17 of the Bureau (*E. S. R.*, 13, p. 232) as far as calcium sulphate enters into the formation of alkali.

Of the forms in which calcium sulphate exists, namely, hemihydrate, dihydrate (gypsum), natural anhydrite, artificial anhydrite, gypsum and natural anhydrite occur together in nature and are the only forms which remain stable in any solution. The solubility of calcium sulphate in water apparently reaches a maximum at about 40° C., when about 2,100 parts per thousand go into solution. The presence of other substances in solution affects the solubility of gypsum, thus salts having a common ion depress the solubility, low concentration solutions of electrolytes which do not have a common ion increase the solubility, non-electrolytes differ in their effects. Solutions containing 48 parts per thousand of sulphuric acid behave like water. These results make it quite clear that the composition of the drainage water from alkali soils which contain a mixture of various salts can not be predicted from the relative solubilities of the salts present.

Reclamation of alkali soils, C. W. DORSEY (*U. S. Dept. Agr., Bur. Soils Bul.* 3½, pp. 30, pls. 1).—This bulletin defines alkali; discusses its origin and accumulation in soils, its effect on crops, methods of preventing alkali accumulation, treatment of alkali soils, including cultivation of alkali resistant crops, use of chemical antidotes, and scraping, flushing, and flooding with and without drainage to free soils from alkali; and gives an account of the alkali reclamation experiments of the Bureau of Soils near Salt Lake City, Utah, Fresno, Cal., North Yakima, Wash., Tempe, Ariz., and Billings, Mont., and a summary of experience gained from these experiments, including possible injury to the land by constant flooding, resulting water-logging of the soil, destruction of tilth and loss of valuable fertilizing constituents, effect of hardpan in retarding leaching, clogging of drains by roots and silt, depth and distance apart for drains, and cost of reclaiming land by flooding and drainage.

As regards the last two points, it is stated that "in practice it is not advisable to place drains less than 3 ft. deep, and depths of 4 or 5 ft. or more give much better results.

"The distance apart at which drains should be placed depends largely on the character of the soil. In heavy soils rapid reclamation may be accomplished with drains 100 to 150 ft. apart. In porous sandy soils the distance may be greater, intervals of 250 to 300 ft. in many cases answering the purpose. The less the interval between drains the more rapid can reclamation be carried on, but the distances given above are conservative.

"As to the cost of carrying on such reclamation, it has been found to depend on the local conditions of each area. While in the central portion of the United States all sizes of drain tile are sold at reasonable prices, this is not the case in the West. . . . Even considering the exorbitant prices at which the farmer must purchase his tile, it is still possible in the greater number of western districts to provide an adequate drainage system for small tracts of land at an

average cost of from \$15 to \$25 an acre. . . . To reclaim lands containing any considerable amount of alkali will cost from \$30 to \$50 an acre, including the cost of installing drains, leveling the land, and constructing necessary levees and dikes, as well as the cost of flooding. The item of leveling has been estimated at from \$5 to \$15, which would cheapen the cost of reclamation just so much in case the land had previously been leveled."

Soil fertility, M. WHITNEY (*U. S. Dept. Agr., Farmers' Bul. 257, pp. 39, figs. 2*).—An address delivered before the Rich Neck Farmers' Club of Queen Anne Co., Maryland, "in which an endeavor was made to place in the hands of the practical farmer the results of recent investigations of this important problem couched in simple language and without a discussion of the technical scientific details upon which the conclusions rest."

The maintenance of soil fertility in grain farming, J. H. PETTIT (*Mo. Bd. Agr. Mo. Bul., 5 (1906), No. 8, pp. 24-38, pl. 1, figs. 4*).—The use of insoluble phosphates in connection with farm manure or green manuring with leguminous plants to supply an abundance of decaying organic matter in the soil, and thus render the insoluble phosphates more available, is advocated.

Our soil needs managing (*Agriculture [Nebr.], 5 (1906), No. 2, pp. 6-13*).—It is pointed out that the loss of fertility in Nebraska soils, which is becoming quite pronounced in many cases, is not due to lack of mineral elements of fertility, but to decline in humus and impairment of physical condition. Methods of cropping and tillage which will repair these deficiencies are discussed.

Example of how analysis of soil may be of use, A. MAYER (*Jour. Landw., 54 (1906), No. 1, pp. 47-50; obs. in Jour. Chem. Soc. [London], 90 (1906), No. 522, II, p. 249*).—The determination of the potash requirements of 4 tobacco soils from Deli, Sumatra, by extraction with dilute hydrochloric acid is reported. Loss on ignition agreed approximately with humus only in case of sandy and sandy peat soils.

Clover sickness of the soil, P. KOSSOVICH (*Zhur. Oputn. Agron. (Russ. Jour. Expt. Landw.), 6 (1905), No. 5, pp. 515-599*).—The author describes an extended series of experiments conducted during 6 years.

Numerous pot experiments were supplemented by a few field experiments. Clover sickness appeared in pot cultures as well as in the field. The soils used were chernozems and podzol clays. Parallel experiments were conducted with soils from clover-sick fields and from fields on which no clover had been raised. The results in general lead to the conclusion that clover sickness is directly connected with the impoverishment of the soil in nutritive substances, usually phosphoric acid, in the first place, and then in potash. The author finds no reason whatever for the assumption of the existence of a specific clover sickness due to the formation in the soil by the clover plant itself of compounds directly injurious to clover.—P. FIREMAN.

The loss of nitrogen from soils, H. SNYDER (*Minnesota Sta. Bul. 94, pp. 188-194*).—In connection with studies of the influence of different methods of farming upon the nitrogen content of soils which have been reported in previous bulletins of the station, samples of soil from typical farms in Minnesota were obtained and analyzed in 1895. Ten years later samples from the same fields were again analyzed, and the losses of nitrogen which had occurred during the period were determined.

The results, as briefly reported in this article, show that "the loss of nitrogen from 4 grain farms in 10 years amounted to from 3 to 5 times more than was removed by the crops. This loss was due to the rapid decay of the humus and the liberation of the nitrogen, which forms an essential part of the humus. The losses of nitrogen from these grain farms were practically the same as

from the experimental plats at the university farm. The results of the tests on the small plats are in accord with the field tests in different parts of the State.

"Where clover was grown, crops rotated, live stock kept, and farm manure used, an equilibrium as to the nitrogen content of the soil was maintained, the mineral plant food was kept in the most available condition and maximum yields were secured."

The nitrogen enrichment of soils through the growth of legumes, F. T. SHUTT (*Canada Expt. Farms Rpts.*, 1905, pp. 127-130).—The exhaustion of soil nitrogen by continuous cropping without manure is illustrated by analyses of virgin and cultivated soils of the Northwest Territories, and pot and plat experiments extending over two years are reported which show that when mammoth red clover was grown on soils and turned under there was a gain during the two years of 179 lbs. of nitrogen per acre to a depth of 9 in. in the pot experiments and 175 lbs. to a depth of 4 in. in the plat experiments.

Inoculation for the growth of legumes, F. T. SHUTT (*Canada Expt. Farms Rpts.*, 1905, pp. 130-132, pl. 1).—Pot and plat tests of pure cultures furnished by the Bureau of Plant Industry of this Department and the Ontario Agricultural College on clover and alfalfa are reported.

Comparisons were made of no treatment, inoculating seed, and inoculating soil in the pot experiments and of untreated and treated seed only in the plat experiments. In the pot experiments there was some increase, especially in case of soil inoculation, the Ontario Agricultural College culture being more efficient than the Bureau of Plant Industry cultures. In the plat experiments on clover inoculation of the seed increased the yield decidedly, the Washington culture being more effective than the Ontario culture. The results of the plat experiments with alfalfa were inconclusive.

The influence of charlock on nitrification in soils, E. GUTZEIT (*Centbl. Bakt. [etc.]*, 2. Abt., 16 (1906), No. 10-13, pp. 358-381; *abs. in Jour. Chem. Soc. [London]*, 90 (1906), No. 525, II, p. 476).—Field experiments and bacteriological studies are reported which show that charlock may be prevented from producing seed by one sprinkling with a 15 per cent solution of iron sulphate, and that the injurious effect of the growth of such weeds on cultivated plants is due not only to their draft upon the plant food, moistures, etc., of the soil needed by the cultivated plant, but also to their influence upon the bacterial life of the soil, especially upon nitrification, which is checked by the draft of the weeds upon the lime and water content of the soil.

Bacteriological methods, using nutrient solutions inoculated with soils and also soil extracts as culture media, were found useful means of studying such questions.

On methods of bacteriological investigation of soils, BUHLERT and FICKENDEY (*Centbl. Bakt. [etc.]*, 2. Abt., 16 (1906), No. 10-13, pp. 399-405; *abs. in Jour. Chem. Soc. [London]*, 90 (1906), No. 525, II, p. 476).—A modification of Remy's method of bacteriological examination of soils (inoculation of a definite culture medium with a fixed amount of soil shaken up in water) was used in the study of the influence of aeration on the decomposition of peptone, denitrification, nitrogen assimilation, and nitrification in sandy, loam, humus, calcareous, and garden soils. The results show that aeration reduced formation of ammonia from peptone, increased denitrification and nitrogen assimilation, and decreased nitrification except in case of the humus soil.

Green manures, F. B. CRUZ (*Estac. Cent. Agron. Cuba Bul.*, 5, pp. 38, pls. 5).—A compilation of information on this subject, adapted especially to Cuban conditions and confined largely to a discussion of the usefulness of cowpeas and velvet beans for this purpose.

The utilization of fertilizers under varying rainfalls, VON SEELHORST (*Separate from Jahrb. Deut. Landw. Gesell.*, 21 (1906), pp. 61-72).—The subject is discussed on the basis of laboratory and vegetation experiments, including those of the author and others. Emphasis is laid especially on the danger of loss of nitrogen in sandy soils, and it is claimed that leguminous cover crops play an important rôle not only as nitrogen collectors and humus formers, but as conservers of soil nitrogen and users of water, thus hindering the washing out of the soluble nitrogen of the soil.

Preservation of manure and its most profitable use, IMMENDORFF and FÖRSTER (*Separate from Jahrb. Deut. Landw. Gesell.*, 21 (1906), pp. 49-61).—Pfeiffer's conclusions regarding the preservation of manure (E. S. R., 14, p. 233) are given and the action of manure preserved in different ways on loam and sandy soils is discussed.

Sewage disposal in small gardens, A. F. T. SOMERVILLE (*Agr. Gaz. N. S. Wales*, 17 (1906), No. 3, pp. 274-276).—Simple methods of disposing of household sewage and wastes are briefly described.

Restoring the fertility of a run-down farm, C. E. THORNE (*Mo. Bd. Agr. Mo. Bul.*, 5 (1906), No. 8, pp. 3-24).—In this paper the bringing up of a run-down soil by the "well-informed use of animal manures, reinforced with such fertilizing materials as may be required to more perfectly adapt these manures to the soils on which they are employed" is discussed.

On the influence of the reaction of the manure upon the yield, K. Aso and R. BAHADUR (*Bul. Col. Agr., Tokyo Imp. Univ.*, 7 (1906), No. 1, pp. 39-46, pl. 1).—An account is given of pot experiments with peas, onions, barley, and rice "to compare the effects of the (neutral) disodium phosphate with the (acid) monosodium phosphate and with calcium superphosphate in presence of ammonium sulphate or of sodium nitrate in sand culture and in soil culture."

The conclusion was reached that "(1) the reaction of the manuring compounds is of very great influence; (2) the combination of ammonium sulphate and disodium phosphate yielded the best result in the case of paddy rice, while the mixture of sodium nitrate and monosodium phosphate produced the highest yield with barley and pea. . . . As a general conclusion, however, it may be mentioned that small changes in the reaction of the manure have often a much greater influence on the yield than might be presumed, and that the effects differ with different crops."

Naturally occurring fertilizers and waste products, F. T. SHUTT (*Canada Expt. Farms Rpts. 1905*, pp. 137-140).—Analyses of marsh mud, semidecayed seaweed, gypsum or land plaster, cotton waste, and flue ashes are reported and discussed.

On the oxidation of nitrogen in the high-tension flame, J. BRODE (*Ueber die Oxidation des Stickstoffes in der Hochspannungs-flamme*. Halle: Wilhelm Knapp, 1905, pp. 63, figs. 19; rev. in *Amer. Chem. Jour.*, 35 (1906), No. 4, p. 358).—This monograph discusses the theory of the process and summarizes work done on the subject from the time of the first experiments of Bunsen and Kolbe, the researches of Muthman, Hofer, and Nernst, the author's experiments carried out during 1904-5 at the Technical High School of Karlsruhe being fully described. The latter dealt especially with the best means of producing the electric flame and with various factors affecting the oxidation efficiency.

The oxidation of atmospheric nitrogen with reference to the manufacture of nitrates and nitric acid, E. RENOUF (*Amer. Chem. Jour.*, 35 (1906), No. 4, pp. 358-367, figs. 6).—This is a review of this subject based upon an address by O. N. Witt, to which reference has already been made (E. S. R., 17, p. 746), and a monograph by J. Brode (see above).

The development of methods and the history of investigations on which they are based is traced, the principles and efficiency of some of the more successful methods are discussed, the essentials of a commercially successful method are enumerated, and the Birkeland and Eyde method, which it is claimed in large measure fulfills these conditions and is the most efficient yet proposed, is described. It has been shown that by this process, with cheap water power, nitric acid can be produced at a cost of less than 1.2 cts. per kilogram for energy or less than one-tenth of the present price of nitric acid. The most important factor affecting cost is the concentration of the dilute nitrous gases obtained. "This problem has not yet found its technical solution, doubtless it will be solved." Progress has been made in this direction by Birkeland and Eyde, resulting in the production of a basic calcium nitrate.

Other methods of utilizing the atmospheric nitrogen are briefly considered. Of the 4 methods thus far proposed 3 are chemical and 1 bacteriological. "The bacterial absorption of nitrogen is, at present, confined to leguminous plants, and unless a more active breed of bacteria can be developed, bacterial action, while valuable, can not replace the use of Chile saltpeter. The formation and decomposition of nitrids is the second method." Technical difficulties have thus far prevented the development of methods based upon this principle. "The third method is Frank's well-known process, in which pure nitrogen, not air, is absorbed by heated calcium carbide, forming calcium cyanamid, which is a valuable fertilizer. This process is on trial technically. Whether the calcium cyanamid can compete with the synthetic nitrate is doubtful. The fourth method is the nitrogen oxidation."

Nitrogenous fertilizer from the air (*Mark Lane Express*, 94 (1906), Nos. 3881, *Fert. and Feed.*, p. 111; 3884, *Fert. and Feed.*, p. 11).—Papers by Professor Silvanus Thompson, already noted (*E. S. R.*, 17, p. 829), and by Sir William Ramsay in the Engineering Supplement of the *London Times*, are briefly reviewed with reference to the following features: (1) The necessity of a future new source of nitrogen for agriculture, (2) methods of production, and (3) fertilizing value of the products.

The general conclusion drawn from the review of these papers is "that agriculture will not languish from want of nitrogen when the nitrate of soda deposits have died a natural death from exhaustion; but that inexhaustible supplies will be available, and probably at lower prices."

The electric production of nitrates from the atmosphere (*Nature [London]*, 73 (1906), No. 1893, pp. 355, 356).—This is an abstract of an address by S. P. Thompson, which has already been referred to (*E. S. R.*, 17, p. 829), discussing especially the success of the Birkeland and Eyde process in Norway.

It is stated that in the experimental factories using this process 500 kg. of nitric acid per year have been produced for every kilowatt of power. "The conditions in Norway were exceptionally good for the furnishing of power at exceedingly low rates. Hence the new product could compete with Chile saltpeter on the market, and would become every year more valuable as the demand for nitrates increased and the natural supplies became exhausted."

New fertilizers prepared from atmospheric nitrogen, C. DUSSERRE (*Chron. Agr. Vaud*, 19 (1906), No. 5, pp. 123-127).—Experiments with lime nitrogen on potatoes are reported, and the probable value of calcium nitrate prepared by electrical methods is discussed.

Water power in Norway and the future of the Birkeland and Eyde discovery, L. GRANDEAU (*Jour. Agr. Prat.*, n. ser., 11 (1906), No. 12, pp. 361, 362, fig. 1).—Statistics are given of the horsepower of various waterfalls (aggre-

gating about 300,000 horsepower) which have been acquired in Norway for the purpose of the manufacture of nitric acid from the air.

On the manurial value of calcium cyanamid, K. Aso (*Bul. Col. Agr., Tokyo Imp. Univ.*, 7 (1906), No. 1, pp. 47-52).—Experiments in open-bottom cylinders sunk in the ground and in pots to compare calcium cyanamid with ammonium sulphate and sodium nitrate on upland and paddy rice and hemp grown on sandy and loamy soils are reported.

All the results show distinctly that calcium cyanamid is an effective nitrogenous fertilizer, the only unsatisfactory result being that with paddy soil. That soil was rich in humus and closely related to moor soils which, according to Tacke and Feilitzen, do not yield such satisfactory results with calcium cyanamid as other soils do. In general the calcium cyanamid was not inferior to ammonium sulphate and Chile saltpeter.

The efficacy of calcium cyanamid under different conditions, R. INAMURA (*Bul. Col. Agr., Tokyo Imp. Univ.*, 7 (1906), No. 1, pp. 53-55).—Pot experiments with *Brassica chinensis* are briefly reported to show that calcium cyanamid was more effective in combination with superphosphate than with neutral phosphate, the acid phosphate neutralizing the ammonium carbonate produced in the soil from the calcium cyanamid and thus bringing about the conditions most favorable to the growth of the Brassica. The combination referred to was much more effective than ammonium sulphate with superphosphate without addition of lime.

Artificial nitrates and the preservation of soil industry (*Agr. Students' Gaz.*, n. ser., 12 (1906), No. 6, pp. 195-198).—This article is an argument in favor of a system of cropping which keeps the soil well covered and stocked with organic matter and against "excessive cultivation of grain with the aid of artificial nitrogenous manures," the view being that the former increases the natural capacity of soils to fix nitrogen and the latter tends to destroy this power.

The oxidation of ammonia to nitrogen-oxid compounds, O. SCHMIDT and R. BÜCKER (*Ber. Deut. Chem. Gesell.*, 39 (1906), No. 6, pp. 1366-1370; *abs. in Amer. Jour. Sci.*, 4. ser., 22 (1906), No. 127, pp. 78, 79).—The two principal methods of oxidizing ammonia, viz. combustion in electric flames, and oxidation by means of contact substances (platinum and platinized asbestos), are referred to, and a series of tests of the efficiency of combustion in tubes filled with platinized asbestos are reported. The total oxidation secured varied from 70.3 to 80.45 per cent, with an average of 75 to 76 per cent, apparently depending mainly upon the temperature. Red heat appeared to be the most favorable temperature for oxidation. The process of producing nitrates is not considered profitable.

A rational process for obtaining ammonia and sal-ammoniac by the utilization of residuary and waste products (*Sci. Amer. Supp.*, 61 (1906), No. 1580, pp. 25314, 25315).—Various processes for obtaining these substances from guano, gas liquor, bones, wool, leather, horn, feather, and similar wastes are briefly described. The formulas for preparing artificial fertilizers from lye waste are also given. The information given in the article is taken from Koller's handbook on the utilization of waste products (E. S. R., 14, p. 717).

On the application of Chile saltpeter as top-dressing for some Japanese crops, K. Aso (*Bul. Col. Agr., Tokyo Imp. Univ.*, 7 (1906), No. 1, pp. 75, 76).—In plat experiments with upland rice and Colocasia there was an increase from top-dressing with sodium nitrate; with sesame there was no increase.

The manurial value of different potassium compounds for barley and rice, K. Aso (*Bul. Col. Agr., Tokyo Imp. Univ.*, 7 (1906), No. 1, pp. 67-72).—From

pot experiments with different potash salts on barley and rice the following conclusions are drawn:

(1) While the chlorid hastened the flowering process and increased grain production, the increase being highest in the case of barley, it reduced to a like extent the yield of the rice; (2) the fertilizing value of the silicate was highest in several cases, and this material may be considered a favorable potash fertilizer for the Gramineæ; (3) while the chlorid acted very favorably in the production of grain, the sulphate was more favorable to the production of straw, in accord with Sebelien's former observations; (4) carbonate was inferior to sulphate in all cases when it was applied with secondary sodium phosphate, a physiologically alkaline manure.

On the effect of various potassic manures on the growth of *Colocasia antiquorum*, S. NAMIKAWA (*Bul. Col. Agr., Tokyo Imp. Univ.*, 7 (1906), No. 1, pp. 73, 74).—In plat experiments it was observed that kainit and 40 per cent potash salt were about equally effective, considerably more so than wood ashes.

On the fertilizing value of steamed Thomas slag, O. BÖTTCHER (*Deut. Landw. Presse*, 33 (1906), No. 27, pp. 231, 232).—Comparative pot and field tests of superphosphate and Thomas slag which had been disintegrated by subjecting it to steam under pressure and ground in the usual way are reported. The pot experiments were made with oats, the field experiments with a mixture of oats, barley, peas, and vetch and on meadow grasses. The results indicate in general that the steamed slag is slightly less effective than the ground.

On the factors which influence the fertilizing action of difficultly soluble phosphates, D. N. PRIANISHNIKOV (*Abs. in Chem. Ztg.*, 30 (1906), No. 37, p. 438).—This is an abstract of a paper presented at the Sixth International Congress of Applied Chemistry at Rome, 1906. The paper discusses this subject from 4 standpoints, (1) the properties of the phosphates themselves, (2) the individuality of the plants on which they are used, (3) the properties of the soil, and (4) the character of the associated fertilizers. Particular attention is given to the fourth point, which has been discussed in previous articles by the author (*E. S. R.*, 17, p. 538).

Thomas-ammonium-phosphate lime, a new mineral fertilizer, E. HASELHOFF (*Fühling's Landw. Ztg.*, 55 (1906), No. 8, pp. 257-264).—This material (see also *E. S. R.*, 17, p. 649) is shown to rapidly undergo decomposition with loss of nitrogen.

Thomas-ammonium-phosphate lime, KETTLER (*Deut. Zuckerindus.*, 31 (1906), p. 390; *abs. in Chem. Ztg.*, 30 (1906), No. 24, *Repert.* No. 7, p. 95).—This material, which is described as an intimate mixture of Thomas slag, ammonium sulphate, and lime residue from sugar factories is highly recommended.

A contribution to the bibliography of the use of sulphate of iron in agriculture, H. E. HORTON (*Chicago, Ill.*, 1906, pp. 69).—This is a bibliography of 452 references, beginning with the work of Thaer in Germany in 1809 and continuing to 1905.

The limestone and lime industry of West Virginia, G. P. GRIMSLEY (*W. Va. Geol. Survey [Pub.]*, 3 (1905), pp. 312-422, pls. 11, figs. 6).—This report contains chapters on distribution and properties of lime in minerals and rocks, the limestones of West Virginia, technology of lime manufacture, and the uses of limestone and lime.

Commercial fertilizers, J. L. HILLS and C. H. JONES (*Vermont Sta. Bul.* 123, pp. 137-204).—This bulletin reports the results of analyses of 130 brands of fertilizers, the output of 12 companies, collected during the spring of 1906, compares the results obtained with those of 4 previous years, and discusses selling price, valuation, and purchase of fertilizers, and the moisture relations of soils.

It was found that 85 per cent of the brands met their guaranties and that the crude stock used in the fertilizers was generally of good quality. The average selling price was \$29.52, the average valuation \$19.38. "A comparison of analyses of brands for 5 years shows in some cases essential evenness and in others considerable variation in composition." The advantages and disadvantages of buying mixed goods and separate ingredients are briefly stated and the cooperative purchase of unmixed fertilizing materials is recommended as more economical.

A general discussion of weather conditions and chemical composition, physical characteristics, biological content, irrigation, drainage, and tillage of soils with reference to control of moisture and better utilization of fertilizers are included in the bulletin.

AGRICULTURAL BOTANY.

The function of silica in the nutrition of cereals, I, A. D. HALL and C. G. T. MORISON (*Proc. Roy. Soc. [London], Ser. B., 77 (1906), No. B 520, pp. 455-477, figs. 11*).—A brief summary is presented of opinions relative to the function of silica in plants.

The authors call attention to the constant and considerable proportion of silica in the ash of certain plants and give an account of field and pot experiments to determine if possible its action. As a result of their investigations they consider that silica, while not an essential constituent of plant food, plays an important part in the nutrition of cereal plants, like barley. The effect of a free supply of soluble silica shows itself in an increased and earlier formation of grain, and it acts by causing an increased assimilation of phosphoric acid by the plant.

There appears to be no evidence that the silica within the plant causes a more thorough assimilation of the phosphoric acid, or that in itself it promotes the transfer of food materials from one part of the plant to the other. The physiological function of silica are found to take place within the plant tissues, and not in the soil as has sometimes been claimed.

Utilization of the nitrogen of the air by plants, T. JAMIESON (*Agr. Research Assoc. [Scot.] Rpt. 1905, pp. 81, pls. 12*).—The author rejects the theory of Hellriegel and others that nitrogen assimilation in the higher plants is confined to the Leguminosæ and a few other orders of plants, where the fixation takes place through the symbiotic action of micro-organisms in the root tubercles.

He claims that nitrogen assimilation is a function common to many plants, through the presence of specialized cells in the epidermis and also specialized hairs on various aerial parts of the plant most abundant in the younger parts of the plant. The basis of this theory seems to be albumin reactions observed in certain thin-walled cells of the epidermis of the leaves and in certain hairs, the author arguing that the formation of the albumin took place where observed, and the absence of the reaction with iodine indicated the transfer of the nitrogenous compounds from the specialized organs to the leaves for the use of the plant.

The action of radium on plants (*Jardin, 20 (1906), No. 457, p. 65*).—The influence of radium on seeds, it is stated, depends upon the thickness of the seed envelop, its distance away from the radium, and the quantity of moist soil covering it. When the moisture is excessive, germination may be retarded or completely arrested. The transformations which take place in the cellular tissues are the same as those occasioned by too much light. Experiments made with other radioactive substances, such as radiotellurium, have given similar

results, while with polonium no definite action has been obtained. If the air is charged with emanations of radium, vegetation is retarded or entirely destroyed.

The presence of hydrocyanic acid in seeds and plants (*Prog. Agr. et Vit. (Ed. l'Est)*, 27 (1906), No. 25, pp. 736-741).—A compilation is given showing the presence of hydrocyanic acid in plants, and its wide distribution is indicated by the various plants which are reported to have been determined as containing it. Among the plants reported as containing this substance are a number of species of Phaseolus, lupines, vetches, lotus, sorghum, flax, cassava, cherry laurel, currants, etc. A brief list of publications relating to this topic is given.

Hydrocyanic acid in Sambucus nigra, L. GUIGNARD (*Compt. Rend. Acad. Sci. [Paris]*, 141 (1905), Nos. 1, pp. 16-20; 26, pp. 1193-1201); and E. BOURQUELOT and E. DANJOU (*Compt. Rend. Acad. Sci. [Paris]*, 141 (1905), Nos. 1, pp. 59-61; 15, pp. 598-600).—Although working independently, the authors simultaneously announce finding in the fresh green leaves of the common European elderberry a glucosid, which under the action of an enzym yields hydrocyanic acid, as much as 126 mg. of the acid being obtained from 1 kg. of fresh leaves.

In the second paper by Bourquelot and Danjou the name sambunigrin is given the glucosid, and some of its properties are described. In subsequent investigations of Guignard the glucosid was found in the cortex, younger shoots, leaves, and immature fruits, the amounts varying appreciably with the stages of growth and disappearing entirely from the fruits when ripe.

In addition to occurring in *S. nigra*, this glucosid was found in the related species, *S. racemosa* and *S. cbulus*. It is said that the presence of the glucosid is associated with chlorophyll activity, but it is not to be considered a reserve material. It is most abundant in the leaves, from which it is not transferred toward the end of the growing season, but remains in the fallen leaves.

On the presence of hydrocyanic acid in certain species of currants, L. GUIGNARD (*Comp Rend. Acad. Sci. [Paris]*, 141 (1905), No. 10, pp. 448-452).—Following his investigations on the presence of hydrocyanic acid in the European elderberry noted above, the author has examined the roots, stems, leaves, and fruits of a number of other plants, and reports in the leaves of the common red currant the presence of a glucosid which yields hydrocyanic acid.

The amount was found to vary with the stage of growth, being most abundant in April and falling off with the ripening of the fruit, and at the end of August the amount was found to be less than one-half that observed earlier in the season. Several related species were also investigated. The tests failed to show the presence of the glucosid in a number of instances, but it was observed in *Ribes nigrum*, *R. aureum*, and *R. uva-crispa*.

The development of amylase during germination, J. EFFRONT (*Compt. Rend. Acad. Sci. [Paris]*, 141 (1905), No. 16, pp. 626-628).—In making a study of the amylase occurring in germinating seed, the author investigated its liquefying and saccharifying power. The saccharifying power increases irregularly with the duration of germination, attaining a maximum, after which it gradually diminishes. The liquefying power is attained more gradually but regularly and, arriving at a maximum, maintains this for a considerable time.

In the course of his investigations the author found that in the germination of malt at a temperature of 15° C. the maximum diastatic action is attained in 10 or 11 days. The amylase which is developed during the course of germination remains in the seed, its migration to the roots and leaves being very insignificant.

The effect of a number of chemicals on germination was also studied. Phosphates, lime water, and a very dilute solution of copper sulphate appeared to

favor germination. Xylol (1 cc. per liter) favors both the germinating power of the seed and the saccharifying power of the enzym. Ammonium chlorid increases the liquefying power of the enzym. and lactic acid, vegetable peptone, and calcium hypochlorite favor germination and also diastatic action.

The osmotic strength of cell sap in plants growing under different conditions, E. DRABBLE and HILDA LAKE (*New Phytol.*, 4 (1905), No. 8, pp. 189-191).—It is claimed that comparatively few observations on the osmotic strength of cell sap in plants growing under different physical conditions have been made, and the authors have undertaken a series of experiments to determine this factor.

The method devised involves the observation of the plasmolysis of the cells, and by this means a number of plants were examined with regard to the strength of their cell sap. A series of sodium-chlorid solutions was made up in various gram-molecule concentrations. Portions of the plant the strength of whose cell sap was to be determined were placed in water. Strips of the epidermis of the leaf were placed in a drop of the solution and gently covered with a cover glass, and when the solution just failed to plasmolyse it was taken as isotonic with the cell sap. It was found most convenient to use plants with red coloring matter in the epidermis, and but little difference was noticed in the strength of sap between the cells containing the red and those containing the colorless materials in the same leaf.

The data presented show that there was a greater concentration of cell sap in those plants which had been most strongly subjected to factors tending to promote a loss of water by transpiration. In considering the effect of the concentration of the cell sap on the absorption of water, it is shown that the concentration exerts an important physiological bearing on the plants. From observations made on plants growing in mountain regions and other dry situations it is determined that a high osmotic strength of cell sap may prove a valuable physiological character in connection with water absorption.

On the sensibility of chlorophyll in tolerant and intolerant species of plants, W. LUBIMENKO (*Compt. Rend. Acad. Sci. [Paris]*, 141 (1905), No. 13, pp. 535, 536).—In continuation of previous observations (E. S. R., 17, p. 651), the author made comparative studies of the carbon-dioxid assimilation of plants tolerant and intolerant to light.

For the intolerant species he selected Scotch pine, European larch, white birch, and the common locust, while for the shade-growing species fir, yew, linden, and beech were chosen. For each of these species 2 series of experiments were carried on, one in artificial feeble light, the other in full sunlight. Spectroscopic studies were made of the chlorophyll solutions of the different species.

It is claimed that the assimilative energy depends on the concentration of the coloring matter in the chloroplast. The curve which represents the assimilative energy following the concentration of the coloring matter reaches its highest limit under natural radiation for the intolerant species and falls below that limit with the tolerant ones. The author raises the question as to whether among tolerant and intolerant plants the physical difference in concentration of chlorophyll is not possibly due to difference in physiological irritability of protoplasm when exposed to light.

The growth of chlorophyll-bearing plants in confined atmospheres in the presence of organic materials, MOLLARD (*Compt. Rend. Acad. Sci. [Paris]*, 141 (1905), No. 7, pp. 389-391).—A report is given of investigations with radishes grown in fermentation tubes in the presence of various forms of starch, sugar, etc., which show that the plants were able to make considerable growth.

utilizing the carbohydrates through their roots. In the absence of light the utilization of sugars took place very slowly, and it appears that for this form of synthesis sunlight is necessary.

Handbook of flower pollination, P. KNUTH, trans. by J. R. A. DAVIS (*Oxford: The Clarendon Press, 1906, pp. XIX+382, figs. 81*).—This volume, which is No. 1 of a series, is based on Müller's work on *The Fertilization of Flowers by Insects*, and it deals with the structure of flowers and the relation of insects to pollination. A bibliography of more than 3,800 titles completes the volume.

Color stimulus and vital functions of plants, J. B. DANDENO (*Rpt. Mich. Acad. Sci., 7 (1905), pp. 44-47*).—A number of experiments are reported upon which were carried on to determine the effects of different portions of the solar spectrum on different functions of plants. Red, yellow, green, blue, and violet colored glass plates were used, which gave results approximating those obtained with pure colors. The detailed results are given, which show that red stimulates growth more than yellow, while yellow is more active in photosynthesis. Blue and violet exercise greater formative influences than the other colors.

A study of the effect of dilute solutions of hydrochloric acid upon the radicles of corn seedlings, F. A. LOEW (*Rpt. Mich. Acad. Sci., 7 (1905), pp. 50-52*).—The author carried on a series of experiments to ascertain the cause of the death of the radicles of germinating grains of corn in extremely dilute solutions of hydrochloric acid. Different lots were subjected to treatment with a 1/256 normal solution of hydrochloric acid and comparisons made with seedlings germinated under normal conditions.

It was found that the amount of acid in dilute solutions of hydrochloric acid is reduced by growing corn seedlings in them. The mineral content of radicles killed in 1/256 normal hydrochloric acid was nearly one-half that of normal radicles. Bacteria and fungi were found to thrive in the solution in which the seedlings had been killed. Seedlings which were killed in the hydrochloric acid solution mentioned above excreted much material rich in potash, and it was found that those grown in distilled water excreted potash, or some other alkali.

The death of the radicles is believed to be caused by a chemical action, from the fact that the amount of acid in solutions in which the seedlings were grown became greatly reduced. The fact that the killed radicles contained less potassium than normal ones and that the solution in which they were killed was rich in potassium, suggests that death is caused by a chemical action between the acid of the solution and the potassium of the radicle. The fact that fungi and bacteria grew vigorously in the solution in which the seedlings were killed, but did not thrive in the distilled water in which the seedlings were growing, suggests that the excretions caused by the acid solution might be some organic compound especially nutritious to these lower forms of plant life.

The toxic action of copper sulphate upon certain algæ in the presence of foreign substances, ELLEN B. BACH (*Rpt. Mich. Acad. Sci., 7 (1905), pp. 48-50*).—A toxic action of copper sulphate of extreme dilution upon certain algæ having been claimed, the author carried on a series of experiments to test the strength required to kill some of the lower algæ in aquarium jars without being injurious to the higher forms.

The presence of foreign substances in the water was found to exercise a very appreciable influence on the strength of solution required, and it appears that the strength of the copper sulphate necessary to free an aquarium from algæ must depend upon the percentage of plant life present, the amount of nonchemical foreign substance in the water, and the kind of water. It seems possible

from the results obtained that if copper sulphate were introduced at the surface of a body of water of considerable depth, the plants at the surface would be killed and absorb sufficient of the copper to render the solution too dilute to be toxic at a greater depth.

International catalogue of scientific literature. R—Bacteriology (*Internat. Cat. Sci. Lit.*, 4, (1906), pp. VIII + 500).—This catalogue is in continuation of previous issues on the same subject, the arrangement being identical with that hitherto described (E. S. R., 14, p. 1049). The present volume is intended to cover the bacteriological literature of 1904 and embraces author and subject catalogues, over 3,600 titles being given. There are many references to articles included that can hardly be called bacteriological, and the American literature is still inadequately represented.

FIELD CROPS.

Field experiments with farm crops, W. SAUNDERS, J. H. GRISDALE, W. T. MACOUN, F. T. SHUTT, J. FLETCHER, R. ROBERTSON, S. A. BEDFORD, A. MACKAY, and T. A. SHARPE (*Canada Expt. Farms Rpts. 1905*, pp. 5-15, 75-90, 116-121, 123, 124, 144-148, 201-232, 265-286, 321-344, 357-361, 364-380, 401-415, pls. 6).—The report on work with field crops at the Canada experimental farms in 1905. Most of the lines of investigation have been previously described (E. S. R., 17, p. 125.)

Wheat.—The results of the uniform test plats show that among 59 varieties of spring wheat Australia F, although badly rusted, ranked first with a yield of 39 bu. 40 lbs. per acre. Hungarian White and Kirsche, varieties added to the test plat this season, are described. The list contains 17 varieties produced at the Central Experimental Farm. Preston, Herisson Bearded, Advance, Pringle Champlain, Huron, and Red Fern were the most productive varieties, as shown by the yields for the last 5 years. These are all bearded varieties, and Pringle Champlain and Red Fern give promise of good milling qualities. Red Fife, White Fife, White Russian, and Laurel were among the most productive beardless sorts, and of these Red Fife and White Fife are the best for making strong flour. Aurora was the earliest variety of spring wheat grown at the Central Experimental Farm this season, while Early Riga, Ebert, Riga, Downy Riga, and Gehm were the earliest in the regular plats.

Of 11 varieties of durum wheat Roumanian, which stood at the head of the list this year with a yield of 40 bu. 20 lbs. per acre, has also given the best yield during the last 5 years. The 18 varieties of winter wheat under test ranged in yield from 30 to 50 bu. per acre, the leading varieties being American Banner, Gold Coin, and Jones Winter Fife, yielding 50 bu., 49 bu., and 45 bu. 20 lbs. per acre, respectively.

At the Nova Scotia farm at Nappan, Pringle Champlain stood first with a yield of 35 bu. among 28 varieties, and Herisson Bearded last with a yield of 13 bu. 20 lbs. Roumanian durum wheat yielded 22 bu. per acre, while Goose, Yellow Gharnovka, and Mahmoudi yielded 17 bu. 20 lbs., 16 bu. 40 lbs., and 14 bu., respectively.

At the Manitoba farm the yields of 30 varieties ranged from 33 bu. 20 lbs. to 52 bu. per acre. The varieties yielding 45 bu. or more per acre were, in decreasing order of yield, as follows: Preston, Laurel, White Fife, Huron, Advance, Red Fife, and Wellman Fife. The yields of 4 durum wheats under test were as follows: Yellow Gharnovka 54 bu., Roumanian 50 bu., Goose 49 bu., and Mahmoudi 46 bu. 40 lbs. per acre. Mahmoudi suffered slightly from rust while the other varieties were free from it. A mixture of 200 lbs. of superphosphate,

100 lbs. of nitrate of soda, and 100 lbs. of muriate of potash per acre, one-half applied before sowing and one-half when the wheat was 2 or 3 in. high gave better results than any other applications used. The soil used for the experiment was a light loam, cropped for many years without fertilizers of any kind.

Wheat grown after peas gave better results than where grown after roots, wheat, corn, or flax. The yields in this same test were also in favor of the use of the shoe drill as compared with the disk drill, and of sowing $1\frac{1}{2}$ in. deep as compared with 3 in. deep. Five varieties of wheat grown in fields varying from 5 to 11 acres in size ranged in yield from 36 bu. 20 lbs. to 48 bu. 12 lbs. A 10-acre field of Preston stood at the head of the list and a 6-acre field of the same variety at the foot. Selected and unselected seed of different varieties were compared at this farm and in each case the yields were in favor of the selected seed.

At Indian Head, where 34 varieties of spring wheat were grown, the yields varied from 16 bu. 40 lbs. to 46 bu. per acre, the leading varieties being Minnesota No. 163, Huron, Haynes Blue Stem, White Fife, McKendry Fife, Bishop, and Wellman Fife, all yielding about 43 bu. per acre. Of 10 varieties grown in field lots a 5-acre field of Huron ranked first with a yield of 47 bu. 12 lbs., and a 10-acre field of Preston gave a yield of 46 bu. 54 lbs. per acre. The average per acre for all varieties in this test was 40 bu. 3 lbs. In a fertilizer test 200 lbs. of muriate of potash per acre, sown before the grain and harrowed in, gave the best results. The 4 varieties of durum wheats grown produced the following yields: Goose 54 bu. 40 lbs., Yellow Gharnovka 52 bu., Mahmoudi 51 bu. 20 lbs., Roumanian 45 bu. 40 lbs. per acre.

At Agassiz, B. C., an attack of the midge nearly destroyed the wheat crop and the 28 varieties of spring wheat gave yields ranging from only 5 bu. 20 lbs. to 16 bu. per acre, and the yields of 4 varieties of durum wheats from 8 to 12 bu. per acre. Abundance ranked first with a yield of 33 bu. 20 lbs. per acre among 6 varieties of winter wheat. Choice Club was badly winterkilled.

Spelt and emmer.—At the Central Experimental Farm 10 varieties of spelt and emmer ranged in yield from 1,380 to 2,400 lbs. of grain per acre. Most varieties rusted but slightly. White spelt and Thick emmer are reported as considerably rusted. Long emmer and Single emmer are to be rejected on account of their extreme lateness in ripening. At Nappan Red spelt and Common emmer gave about equal yields of grain, but Red spelt produced 50 per cent more straw than Common emmer. The yields of these crops at the other farms are reported without comment.

Oats.—At the Central Experimental Farm 67 varieties of oats were grown this season, including 7 varieties originated at the farm. Banner, White Giant, and Überflus, yielding 84 bu. 4 lbs., 84 bu. 4 lbs., and 80 bu., respectively, stood at the head of the list. Banner, White Giant, Lincoln, and Virginia White Abundance have been most satisfactory during the past 5 years among the white varieties; Überflus and Holstein Prolific among the mixed sorts; Mennonite and Columbus among the pure yellow oats, and Black Beauty among the black varieties.

At Nappan 39 varieties of oats were under trial. The yields ranged from 45 bu. 30 lbs. to 92 bu. 32 lbs. per acre. Improved Ligowo and Mennonite ranked first with yields of over 90 bu.

Of 41 varieties of oats grown at Brandon, Golden Giant, Improved American, and Goldfinder were the most productive sorts. The yields of all the varieties at this farm ranged from 82 bu. 12 lbs. to 135 bu. 10 lbs. per acre. At this farm oats on summer fallow yielded 115 bu. 30 lbs.; after corn, 106 bu. 16 lbs.; and after roots, 71 bu. 0.06 lb. per acre.

At Indian Head the yields of 41 varieties of oats varied from 73 bu. 18 lbs. to 117 bu. 22 lbs. The leading 10 varieties, given in decreasing order of yield, produced 110 bu. or more per acre: Goldfinder, Pioneer, Siberian, Joannette, Golden Tartarian, Twentieth Century, Columbus, Golden Beauty, American Triumph, and Tartar King. In field lots from 2 $\frac{1}{4}$ to 10 acres in size Banner, among 12 different varieties on a 10-acre field, ranked first with a yield of 107 bu. 13 lbs. per acre. The average yield per acre of these varieties was 93 bu. 30 lbs. Banner also stands first at this farm in a comparison of 9 varieties for 5 years.

At the British Columbia farm Abundance, Golden Fleece, and Siberian gave the best results. These varieties were also least affected with rust.

Barley.—In 1905 among the 6-rowed varieties of barley Nugent, a variety produced at the Central Experimental Farm, gave the best yield at that institution. The yields this year ranged from 40 bu. to 72 bu. 24 lbs. per acre. Twenty-nine varieties, including 12 produced at the farm, were grown. The most productive sorts for the last 5 years were Stella, Odessa, Nugent, Mensury, and Blue Long Head, and among the earliest are Odessa and Mensury. Of 25 varieties of 2-rowed barley, including 8 produced at the farm, Swan Neck, Danish Chevalier, and French Chevalier led in yield.

The average returns for the last 5 years at this farm show that French Chevalier, Danish Chevalier, and Canadian Thorpe were most productive. Standwell, Beaver, and Princess Svalöf also gave good results, but the last mentioned is late in ripening. Beaver, the earliest 2-rowed variety as shown by 5-year tests, ripens about 2 or 3 days before French Chevalier. Beardless and hullless varieties of 2-rowed barley have been found deficient in strength of straw.

At the experimental farm in Manitoba 19 6-rowed and 15 2-rowed varieties of barley were compared. Of the 6-rowed varieties Mensury produced the stiffest straw, and Mansfield, a crossbred variety produced at the Central Experimental Farm, led in yield with 77 bu. 24 lbs. per acre. This variety also gave the highest average yield for the past 6 years. Gordon, the leading 2-rowed variety, produced 67 bu. 44 lbs. per acre, followed by Jarvis, Harvey, French Chevalier, and Danish Chevalier, all producing over 60 bu. Barley after roots gave a better yield than after corn or on summer fallow.

At Indian Head the leading varieties of 2-rowed barley were Beaver, Invincible, Gordon, and Standwell, and the leading 6-rowed sorts, Stella, Nugent, Claude, Blue Long Head, and Yale. In field lots of several acres each Odessa, Claude, and Mansfield yielded 73 bu. 34 lbs., 72 bu. 22 lbs., and 70 bu. 45 lbs. per acre, respectively. The average yield per acre for 10 varieties so grown was 63 bu. 17 lbs. Nine varieties grown in field lots for 5 years ranged in growing period from 99 to 110 days, and in yield from 50 bu. to 64 bu. 46 lbs. per acre.

Rye.—At the Central Experimental Farm at Ottawa spring rye produced 40 bu. per acre, and 4 varieties of winter rye ranged in yield from 28 bu. 12 lbs. to 36 bu. 4 lbs., the leading variety being Mammoth White.

At Indian Head 53 bu. 32 lbs. per acre was secured from spring rye and 40 bu. from winter rye. The following yields of winter rye sown on October 15 were secured at the experimental farm for British Columbia: Thousand Fold 47 bu. 48 lbs., Mammoth White 46 bu. 24 lbs., Giant 44 bu. 16 lbs., and Emerald 42 bu. 8 lbs. per acre.

Corn.—This season Eureka, Pride of the North, and Thorobred White Flint were the leading varieties of corn at Ottawa. The average yield from drills was 30 tons 987 lbs., and from hills, 28 tons 1,221 lbs. per acre. Thorobred White Flint, Eureka, and Red Cob Ensilage gave the best results at the experimental farm for the Maritime Provinces; Longfellow, Angel of Midnight, and Compton Early at the experimental farm for Manitoba; Eureka, Superior Fodder, and

Pride of the North at the experimental farm for the Northwest Territories, and Pride of the North, Thorobred White Flint, and White Cap Yellow Dent at the farm for British Columbia. Distance experiments with varying results are also reported.

Peas.—Among the most productive varieties grown for the past 5 years at the Central Experimental Farm are Golden Vine, Victoria, Mackay, White Wonder, Prince, Canadian Beauty, and Prussian Blue. Chancellor, perhaps the earliest variety at the farm, ripens about 4 days before Golden Vine. Fifteen of the 29 varieties tested this season were produced at the farm. Mummy, the leading variety at Nappan, yielded 39 bu. 20 lbs.; Early Britain ranked first at Brandon with 51 bu. 40 lbs.; Kent at Indian Head, yielding 70 bu., and Paragon at Agassiz with 50 bu. per acre.

Potatoes.—Of 47 medium and late varieties of potatoes grown at Ottawa, Dalmeny Beauty, Rural Blush, Ashleaf Kidney, Manistee, Norcross, Carman No. 1, and Sabean Elephant, given in the decreasing order of yield, produced over 400 bu. per acre, Dalmeny Beauty giving a yield of 475 bu. 12 lbs. and Sabean Elephant of 404 bu. 48 lbs. Of 32 early varieties Maule Thorobred gave the best yield. The 12 best-yielding varieties during the past 5 years have given average yields ranging from 418 bu. to 456 bu. 43 lbs. per acre. The 3 leading varieties were Dr. Maercker, Late Puritan, and Carman No. 1. In a test of resistance to blight Holborn Abundance ranked first and was also one of the most productive sorts grown. The average increase in yield per acre of marketable potatoes, apparently due to spraying with Bordeaux mixture, was 92 bu. 31 lbs. Of different solutions used in spraying Bordeaux mixture and Paris green were most effective.

At Brandon the yields of 49 varieties of potatoes ranged from 291 bu. to 887 bu. 20 lbs. per acre. Dreer Standard headed the list in productiveness. The 12 varieties standing next varied in yield per acre from 700 bu. to 799 bu. 20 lbs.

At Indian Head, Seedling No. 7 and Vermont Gold Coin headed the list with yields per acre of 640 bu. 48 lbs. and 625 bu. 24 lbs., respectively. At Agassiz Late Puritan and Empire State stood first in yield among 44 varieties.

Flax.—Of 7 varieties grown at Ottawa, Riga, Russian, and Novarossick yielded 10 bu. 40 lbs., 9 bu. 30 lbs., and 9 bu. 10 lbs. per acre, respectively. At Brandon much better yields were produced this season and the leading varieties, Russian and Improved Russian, gave yields of 30 bu. 40 lbs. and 30 bu., respectively. Sowing at the rate of 50 lbs. of seed per acre again gave the best yields at Indian Head. The leading variety at this farm was Yellow Seeded.

Buckwheat.—Five varieties of buckwheat were sown June 20 at Nappan and harvested September 1. Siberian, or Tartarian, ranked first in yield with 43 bu. 16 lbs. per acre. Rye buckwheat, with 37 bu. 24 lbs., standing next.

Root crops.—At Ottawa, turnips, mangels, carrots, and sugar beets were sown on May 10 and May 23, and in each case the first sowing gave much the better yields. The leading varieties and their yields per acre were as follows: Perfection Swede turnip 36 tons 500 lbs., Half Long Sugar White mangel 52 tons 600 lbs., Mammoth White Intermediate carrot 32 tons 500 lbs., and Danish Red Top sugar beet 40 tons 1,300 lbs. These yields represent the first sowing.

At Nappan the first sowing of root crops was made about May 25 and the second about June 8. The results were also much in favor of the early sowing. The leading varieties were Magnum Bonum turnip, Mammoth Yellow Intermediate mangel, Red Top sugar beet, and Improved Short White carrot. The use of commercial fertilizers in addition to an application of 20 tons of barnyard manure per acre did not prove profitable for these crops. The work and results with roots at Brandon, Indian Head, and Agassiz were similar to the results just given.

Tobacco.—Forty-nine varieties of tobacco were grown at Ottawa this season and of 7 varieties having done well in previous years and grown in larger areas, Connecticut Seed Leaf and Kentucky Burley gave the largest total yields per acre of all grades of leaf. Little Oronoka and Lacks were ripe on September 15 and the other varieties were nearly ripe.

Grasses and other forage crops.—Inoculated and uninoculated seed of clover and alfalfa gave the same results with reference to nodules on the roots at Nappan, but the clover in each case had many more nodules than were found on the alfalfa. Green soy beans produced a much larger yield than white soy beans, and Italian millet far outranked 5 other varieties grown. At Brandon common red clover gave a heavier yield than alfalfa. Algerian, the leading millet, produced 6.1 tons of hay per acre. At Indian Head in 1904 alfalfa gave much larger yields of hay than several grasses with which it was compared. At Agassiz 3 cuttings of clover were secured for the silo, making a total of 32 tons 1,590 lbs. per acre. Clover was found cheaper for silage than corn.

Miscellaneous.—A report is given on the inspection of different experimental farms and on the growing of winter wheat in Alberta and of different farm crops in the Yukon country. The grades of wheat in the Manitoba inspection division and the most important varieties long under cultivation in Canada are described.

Forage plants and cereals at Highmore Substation, 1904-5 (South Dakota Sta. Bul. 96, pp. 23-60, figs. 5).—A brief history and description of the station is given, together with the monthly rainfall records for the years 1888 to 1905, inclusive, and the results of forage plant and cereal investigations for 1904-5 are recorded.

Forage plants, W. A. Wheeler and S. Balz (pp. 23-45).—Of 5 varieties of alfalfa from seed sown May 12, 1905, an average yield of 1,750 lbs. of hay per acre was secured. Oasis stood first with an average yield of 1,930 lbs. The average height of the different varieties was 1 ft. 3 in. In the breeding experiments with alfalfa it was observed that the varieties from Turkestan showed greater variation than those from America or southern Europe. The Turkestan alfalfa produced a larger percentage of coarse, shrubby plants than the other varieties. Owing to an excessive rainfall a good stand of red clover was secured. The barnyard millets were found low in quality and the pearl millets, or *Pencillaria*, too late for the seasons.

Good results were secured with broom corn, or proso millets, and foxtail millets. Broom corn millets matured in from 75 to 85 days and foxtail millets from 85 to 110 days. In 1904, when July and August were very dry, the broom corn millets matured a small crop of seed, but none of the foxtail millets matured. In 1905 good crops were secured from all varieties tested, the large amount of moisture especially favoring the foxtail varieties. In 1904 the broom corn millets produced an average of 1 bu. 35 lbs. of seed per acre, while the following season they produced 29 bu. 37 lbs. Foxtail millets produced a yield of an average of 42 bu. 22 lbs. per acre in 1905.

In plant-breeding work with millets grown in centgeners the average results for all varieties show an average of 99 days for the growing period, 17 lbs. 13 oz. as a total weight of 100 plants, and 6 lbs. 9 oz. as the weight of seed secured from 100 plants. The growing period ranged from 93 to 103 days and the total weight of 100 plants from 16 lbs. 1 oz. to 20 lbs. 12 oz. The light and dark seeded varieties have been separated for breeding work and their comparison is now in progress.

A large number of introduced and native grasses have been under test, but only *Bromus inermis*, slender wheat-grass, western wheat-grass, wild rye-grass, and wild timothy are considered worthy of further trial. Seed of *Bromus inermis*

mis from 30 or 40 different sources has been tried and quite a difference was noted in the character of the plants from the different lots of seeds. The yields of a one-fourth acre plat of slender wheat-grass were 980 lbs., 908 lbs. and 1,920 lbs. per acre for the years 1903, 1904, and 1905, respectively. The first two years that this plat was started no hay was cut. Wild rye-grass gave results similar to those of slender wheat-grass.

In 1905 experiments were conducted to compare some northern-grown varieties of corn. Of the early varieties Minnesota No. 13 gave the largest yield and produced the best quality of corn. In a series of rotation plats this variety yielded an average of 46 bu. per acre. A plat of flint corn planted May 25 ripened September 26 and yielded 64 bu. per acre. All varieties of sorghum were a failure in 1904 on account of the late drought, but in 1905 a large amount of fodder was produced, and some varieties gave a good crop of seed. Montana No. 341 was the earliest variety grown. In 1905 this variety grew to a height of 9 ft. 8 in., and produced 6 tons and 88 lbs. of fodder per acre.

Cereal investigations, J. S. Cole and S. Balz (pp. 45-60).—This work is carried on in cooperation with the Bureau of Plant Industry of this Department. Earlier results have been previously noted (E. S. R., 16, p. 364). Of durum wheat 49 varieties have been under trial. In 1903 the yield ran from 9 bu. to 20.2 bu. per acre, the average being 14.9 bu., in 1904 from 8.2 bu. to 23.8 bu., with an average of 14.7 bu., and in 1905 from 20.8 to 38.7 bu. per acre, the average being 28.6 bu. The average yield per acre of the 10 best varieties of durum wheat for the three years varied from 20 to 24.4 bu. The leading varieties of other grains and their yields in 1905 were as follows: Pedigree blue stem, common bread wheat, 24.8 bu., Horn barley, 54.4 bu., Sixty Day oats, 64 bu., Emmer No. 1524, 2,410 lbs., winter rye, 25.7 bu., winter wheat, 6.8 bu. The winter wheat was badly winterkilled, but the winter rye made nearly a perfect stand.

Studies were also made on the effects of the immediately preceding crop on the yield of grain in an unfavorable season, and the experience points out that as good a crop of grain can be grown following a well-tended crop of corn as can be grown after the best summer-fallow. In a test with heavy and light seed made in 1905 the heavier seed in every case but one gave the heavier yield. In the average of seven trials there was a difference of 2.17 bu. per acre from an average difference of 14.3 lbs. per bushel in the weight of the seed. In some instances the lighter seed produced a heavier crop of straw but a lighter yield of grain than was secured from the heavier seed.

Agriculture and animal husbandry [field crops], G. H. TRUE (*Nevada Sta. Rpt. 1905, pp. 40-42, pl. 1*).—Brief notes on the station work during the year are presented.

The experiments were conducted in cooperation with this Department, and their purpose was to determine the least amount of water consistent with good growth in growing crops under irrigation. It was found that on the station farm twice as much water is required to grow a crop of alfalfa as in some other localities. On a farm in the Lower Humboldt Valley 3.54 ft. of water were used, while on the station farm the same season 7.60 ft. were applied. It is pointed out that these differences in the amounts of water used are due to the difference in the water-holding capacity of the soil. A yield of 25,919 lbs. of corn fodder per acre was secured with 4 irrigations and a total amount of water equal to about 2.50 ft. One-half acre of potatoes, cultivated once and receiving 6 irrigations aggregating 4.65 ft. of water, yielded 300 lbs. of marketable potatoes less than a one-half acre plat cultivated after every one of 5 irrigations and receiving only 3.64 ft. of water.

In a comparison of the flooding and furrow system of irrigation in growing wheat, the furrowed crop received a depth of 1.705 ft. of water and yielded 2,142 lbs. of grain to the acre, and the flooded tract received 1.42 ft. of water and yielded 2,033 lbs. These experiments duplicated with oats resulted in a better yield from flooding. Kubanka macaroni wheat received 1.85 ft. of water and yielded 1,548 lbs.; Velvet Don, 1.84 ft. of water and yielded 1,274 lbs., and Polish, receiving 2 ft. of water, yielded 1,378 lbs. of grain.

Investigations on the drying of grain, with especial reference to barley, L. KIESSLING (*Vrtiljschr. Bayer. Landw. Rat.*, 11 (1906), No. 1, pp. 13-137).—Similar work by other investigators is reviewed, and the author's results are shown in tables and are discussed at length.

Barley of good germinative capacity, when dried under temperatures ranging from 34 to 98° C., was reduced in germinative power, the greater reductions being shown in connection with the higher temperatures and the longer periods of drying. Of these two factors the temperature exerted the greater influence. A gradual heating was less injurious than a sudden rise of temperature in the barley. The germinative energy was more subject to the influence of heat than the germinative ability, and for this reason the number of sprouted kernels is not considered as a criterion of their viability, as many of them do not live. It is also stated that drying at high temperatures affects the development of the embryo.

Other grains, low in germinative ability, were in some cases improved by heating, but otherwise the effects were the same as with barley. The author points out that on account of the individuality of the seed and the variation in the methods of drying, the data secured in experiments of this kind do not warrant a definite general application.

Tests were also made to study the effect of drying on the germination of immature barley. Immediately after harvesting barley germinates poorly, but it improves from day to day, and generally after having been properly stored for about two months it reaches its maximum germinative ability. The water content of the barley kernel did not seem to influence the rapidity of germination, and when the moisture in the grain was prevented from evaporating its germinative energy was, nevertheless, improved by storing, but this improvement was slower than when the air had access to the stored grain. Exposing the kernels to the rays of the sun also improved the germinative power, and storing for a time in the heads was similarly beneficial. The germinative quality of grain from different varieties, in the same conditions of ripeness and age, varied considerably.

The results of other experiments are regarded as indicating clearly that immediate thrashing after harvesting is likely to reduce the germinative quality of barley, and that it is best to store the crop in the sheaf for several months.

Artificial drying further proved beneficial in retarding fungus growth on the grain. A high water content in barley before drying and a high drying temperature reduced the viability of the sprouted grain, principally in those kernels which were the first to germinate. The general conclusion is drawn that while artificial drying promotes the rapidity of germination it may also reduce the germinative ability, that the curing of barley by going through the sweating process while in storage can not be replaced by artificial heating, and that fresh material under the application of heat must be handled with care, if serious injury is to be avoided.

Preservation of the ability of seeds to germinate, A. MAYER (*Jour. Landw.*, 54 (1906), No 1, pp. 51-56).—An account of an experiment in which seed of

Brassica oleracea, which are rich in fat, and of *Medicago sativa*, poor in fat, were preserved in the presence of burnt lime and of concentrated sulphuric acid or calcium chlorid.

The results of the experiment were as follows: Original germination of the Brassica seed 98; germination 4 years later, when preserved with burnt lime 88; 11 years with sulphuric acid 10.5, and with calcium chlorid 54.8 per cent; water content 6 per cent. With *M. sativa*, not counting the "hard" seed, the following results were obtained: Original germination 88.3; germination with 11 years' preservation with sulphuric acid 79.5, and with chlorid of calcium 85. In the case of *M. sativa* complete drying of the seed with the sulphuric acid had practically no effect on germination, but rather helped to preserve the seed.

With the oily Brassica seeds the results were less favorable, the medium drying in the presence of lime for 4 years giving much better results than complete drying with sulphuric acid. The point is made that the ability of seeds to germinate does not necessarily continually decrease with age, but that this is dependent in considerable measure upon the dryness at which they are preserved.

Experiments in the manuring of a meadow, J. H. STEWART and H. ATWOOD (*West Virginia Sta. Bul. 101, pp. 251-262, pls. 2*).—For 6 years an unfertile upland meadow was treated with barnyard manure and commercial fertilizers, and the yields of hay per acre were increased from a little more than 1½ tons to over 5½ tons.

It was found that both systems of manuring were highly profitable. The barnyard manure, when applied in the fall and thoroughly harrowed in the spring, became so disintegrated and incorporated with the soil that it was not raked up with the hay in harvesting. The use of barnyard manure at \$1 per load, when spread upon the meadow, was found to be more profitable than the use of commercial fertilizers, and the annually repeated top-dressing of barnyard manure also left the soil in better condition than the other treatment.

Fertilizer experiments on meadows, A. GRETE (*Landw. Jahrb. Schweiz, 20 (1906), No. 4, pp. 259-286*).—Fertilizer tests were conducted for several years in poor, sandy soil. It was found that with a production of 3,000 kg. of dry matter per hectare a lack of phosphoric acid in the soil became manifest. The insufficiency of potash supply in the soil was also shown when the maximum of production, without the use of potash in the fertilizer, was reached. The third year of the experiment the application of potash was capable of producing in the yield more than 3,000 kg. of dry matter per hectare. The use of nitrogen on these meadows was not profitable.

The quality of the grass was improved through the use of potash and phosphoric acid and reduced when nitrogen was given. The plat receiving potash and phosphoric acid produced in each of the three years the highest quantity of protein. It was observed that 61 per cent of the phosphoric acid and 100 per cent of the potash applied was recovered in the crop. In addition to the potash recovered 1.8 per cent was taken from the soil.

Alfalfa, F. C. BURTIS and L. A. MOORHOUSE (*Oklahoma Sta. Bul. 71, pp. 12*).—In connection with the general directions for alfalfa culture in Oklahoma, fall seeding is recommended, particularly for the less adapted soils. At the station, on a clay loam underlaid by a very stiff, impervious subsoil, an average of 2.32 tons of alfalfa hay per acre were secured during 4 years, the yields increasing from 1.76 tons in 1902 to 3.13 in 1905. On another series of plats, on the same kind of soil, 3.08 tons of hay were secured on an average for 3 years, while a field of about 5 acres gave an average per acre for 4 years of 2.69 tons, the maximum yield in any one year from 5 cuttings being 4.20 tons.

The influence of insufficient potash in the soil on the growth of *Phaseolus vulgaris nanus*, VON SEELHORST (*Ztschr. Pflanzenkrankh.*, 16 (1906), No. 1, pp. 2-5).—Observations were made on a series of different crops and it was found that cereals were not much benefited by a large supply of potash in the soil, while beets and potatoes, and especially leguminous crops, particularly this species of *Phaseolus*, made a much better growth when the supply of potash was large. Where the beans were grown for a number of years on a soil rich in potash, the lower yields secured from year to year showed that the available potash compounds were being reduced. Of all the crops under experiment beans were the most sensitive to lack of potash in the soil.

Alsike clover, H. A. MORGAN and M. JACOB (*Tennessee Sta. Bul.*, Vol. XVIII, No. 3, pp. 22-27, fig. 1).—The failure of red clover and the use of alsike as a substitute for this crop is discussed, and general notes on the history and value of alsike clover, together with directions for its culture and its use for hay and pasture, are given.

Correlation in fodder beets, H. BRIEM (*Fühling's Landw. Ztg.*, 55 (1906), No. 7, pp. 246-253).—The results of different investigators of this subject are brought together and discussed.

The data presented indicate that of 100 Mammoth fodder beets weighing from 400 to 600 gm. each, 25 specimens contained 9 per cent of sugar; of those weighing from 600 to 800 gm., 28 contained 8 per cent of sugar; and those weighing from 800 to 1,000, 1,000 to 1,200, and 1,200 to 1,600 gm., 39, 31, and 39 individual beets, respectively, contained 7 per cent of sugar. In each case the largest number of beets of a uniform sugar content is presented. It is further shown that with the increase in weight of the beet the percentage of sugar decreases, but that the absolute amount of sugar in the beet increases. In experiments made by Maas beets weighing from 800 to 1,000 gm. contained 58.98 gm. of sugar, or 6.42 per cent, while beets weighing over 2,000 gm. contained 111.36, or 4.80 per cent.

The relation of variety to sugar content was studied by Wohltmann in a series of storage experiments, in which he found differences in the loss of sugar while the beets were in the silo varying from 60 to 20 per cent. In selecting for breeding purposes the same author found that of 6,115 individual beets of the most common varieties, 26 per cent of the Mammoth beets, 15 per cent of the Oberndorf, and 5 per cent of the Eckendorf contained 8 per cent of sugar.

With reference to the relation of the quantity of leaf produced to the sugar content of the beet, Maas concluded from his work that the weight of leaf matter is primarily dependent upon the variety. He found that the percentage of leaf weight decreased as the size of the beet increased, but that the absolute weight of leaf increased. The thickness of the leaf also increased with the weight of the beet. In thick beets the same amount of leaf produced much more sugar than in thin individuals. A strong development of the stalks was unfavorable to the production of sugar. The results further showed that a high sugar content is correlated with early maturity and a thick leaf.

The hop and its constituents, edited by A. C. CHAPMAN (*London: The Brewing Trade Review*, 1905, pp. 99, pls. 10, figs. 3).—In this monograph on the hop plant the topics discussed, treated by different authors, include the physical characteristics of a good hop, fertilization and cross fertilization of the plant, the manuring of the crop, the cold storage of hops, the essential oil, the bitter substances and resins of hops, hop alkaloids, and the part played by hop tannin in brewing.

Oat experiments, R. B. GREIG and J. HENDRICK (*Aberdeen and No. of Scot. Col. Agr. Bul.* 6, pp. 28).—The leading grain-producing varieties in comparative tests were Banner, Thousand Dollar, Newmarket, and Siberian. The older local

varieties in general produced more straw, but the excess of grain was more than equal to the deficiency of straw in the new varieties. A chemical study of the different varieties is reported, and the percentages of husk and kernel in air-dried samples, the composition of the kernels and of the straw are given in tables.

The potato crop, D. YOUNG (*Trans. Highland and Agr. Soc. Scot., 5. ser., 18 (1906), pp. 143-165, figs. 5*).—The history of the potato is reviewed, statistics on the crop given, the process of hybridizing described, and disease resistance of varieties and the spraying and manuring of the crop discussed.

Fertilizer experiments with sugar beets, A. H. DANIELSON (*Colorado Sta. Bul. 115, pp. 23*).—Fertilizer experiments were conducted from 1903 to 1905, inclusive. This work was in part cooperative with the Bureau of Chemistry of this Department.

In 1903 the best financial results were received from the plat treated with 150 lbs. of nitrate of soda per acre. The results of this season further show that the use of 15 tons of cow manure per acre was more profitable than the use of 30 or 60 tons. In 1904 on a different field the most profitable results were secured where 330 lbs. of acid phosphate rock and 165 lbs. of nitrate of soda were applied per acre. The use of nitrate of soda alone, however, gave very nearly as good results. The third year the largest financial returns were secured with 100 lbs. of sulphate of potash and 199 lbs. nitrate of soda were given per acre. The use of 426 lbs. of nitrate of soda alone, however, yielded only 11 cts. per acre less than the plat on which it was applied with the sulphate of potash.

The general conclusion is reached that the soils in question contain ample supplies of potash and phosphoric acid and an excess of lime, while being somewhat deficient in nitrogen and humus. Nitrogen in the form of nitrate of soda was the only element showing a decided effect in increasing the yield over the cost of application. Potash and phosphoric acid in the fertilizer applications seem to neutralize the effect of nitrate of soda upon the yield, although the quality of the beet was good. Applying the nitrate of soda at the time of planting, or in part at this time and in two applications later, gave practically the same results.

The net profit from reasonable quantities of manure seemed to be mainly obtained in the residual effects in the second year, while the third year its use seemed to have no further influence. Refuse lime cake from the sugar factories showed no value as a fertilizer. Soluble fertilizers applied to the seed improved the germination. It was found that the tops were about 44 per cent of the weight of the clean beets. A 15-ton crop, therefore, produces 6.6 tons of fresh green tops, which will air-dry to about one-eighth of the original weight, or 0.8 of a ton.

The influence of stripping on the yields of cane and sugar, C. F. ECKART (*Hawaiian Sugar Planters' Sta., Div. Agr. and Chem. Bul. 16, pp. 24, dgm. 4*).—Three series of experiments on the influence of stripping sugar cane are given, and the results indicate that in some instances the process is profitable, while in others it is not. The data are regarded as showing that careful field experiments should be carried out on each plantation, to determine whether or not the dry leaves may be economically removed from the cane, and plans for carrying out such experiments are outlined.

Experiments with fertilizers on tobacco, C. E. THORNE (*Ohio Sta. Bul. 172, pp. 215-230, dgm. 1*).—The plan of these experiments from previous results have been heretofore shown (E. S. R., 17, p. 245).

While the work has not been carried on far enough to justify definite conclusions, the latest results indicate that for tobacco on soil in the Miami Valley the use of barnyard manure is more profitable than the use of commercial fertilizers, but where it is not obtainable commercial fertilizers may be substituted with excellent temporary effect, but with a reduced net profit as compared with the use of the manure. The results at this stage also appear to show that the greatest total yield is secured from the use of an application containing relatively more phosphorus in proportion to nitrogen than is found in ordinary barnyard manure. Potash in the fertilizer regularly increased the yield, but at very small profits, and when barnyard manure is used the application of potash, in a commercial form, becomes necessary. As a carrier of nitrogen, sodium nitrate appeared to be much more effective for tobacco than tankage.

Turnip experiments, 1904, J. HENDRICK and R. B. GREIG (*Aberdeen and No. of Scot. Col. Agr. Bul. 4, pp. 36, dgm. 2*).—The results of cooperative fertilizer experiments indicated that on the soils in question, of which the chemical and mechanical analyses are presented, potash is more important than nitrogen for turnips.

Superphosphate or basic slag, or a mixture of the two, seemed to be the most profitable source of phosphoric acid. It is stated that in a good year a complete dressing of commercial fertilizers in medium quantity, with 10 tons of barnyard manure, will give satisfactory returns. More than 10 tons of barnyard manure is not recommended. Ground lime, applied when the turnips are sown, generally decreases the crop. Chemical analyses were made of different parts of the turnip, and it was found that the upper half contains a higher percentage of dry matter than the lower, and that the outside part next the rind is richer in dry matter than the inner part.

Nitrogenous manures for turnips, R. P. WRIGHT (*Trans. Highland and Agr. Soc. Scot., 5. ser., 18 (1906), pp. 93-109*).—The results of cooperative experiments for several years are reported and the conclusion is drawn that the largest increase in crops may be secured by applying one-half of the nitrogenous manure in the drills in the form of sulphate of ammonia, and the other half as a top-dressing in the form of nitrate of soda.

Culture experiments with vetches, F. G. STEBLER and A. VOLKART (*Landw. Jahrb. Schweiz, 20 (1906), No. 4, pp. 243-258, pl. 1*).—A comparative test of different species and varieties of vetches secured from different countries is reported. Brief notes on various species are given.

The results secured indicated that the yield of summer vetches depends very largely upon the time of sowing the seed, the best results being obtained from early sowing. Field peas were not found equal in value to vetches as a catch crop. It is pointed out that satisfactory results can be obtained only from good, pure seed. The heaviest yields were secured from vetches obtained from Alsace, Hungary, and Burgundy. Bulgarian vetch was one of the least satisfactory.

Fertilizer tests with wheat and corn, II. SNYDER (*Minnesota Sta. Bul. 94, pp. 165-187*).—Nitrogen, phosphoric acid, and potash fertilizers were applied, singly and in combination, to one-fourth acre plats of wheat to determine the influence of these fertilizers on the character of growth and on the yield. In these experiments 150 lbs. of a complete fertilizer, containing 1.68 per cent of nitrogen, 15.46 per cent of phosphoric acid, and 1.9 per cent of potash were used. The phosphate fertilizer consisted of 80 lbs. per acre of treated rock phosphate, containing 17.56 per cent of phosphoric acid, and the potash fertilizer of 40 lbs. of kainit, containing 13.5 per cent of potash. Nitrate of soda, containing 15.06 per cent of nitrogen, was used in quantities of 40 lbs. per acre. The complete

fertilizer was valued at \$25 per ton, the acid phosphate at \$15, the nitrate of soda at \$50.

These experiments were cooperative and were conducted in different counties in the State and at the station. On an old soil, reduced through excessive grain culture, the use of commercial fertilizers did not result in raising the yield more than 3.6 bu. per acre. On a grain-cropped soil, where clover had been grown, phosphoric acid and potash increased the yield, while nitrogen did not prove economical. In one experiment phosphoric acid alone caused an increase in yield of 4 bu. per acre, and in other tests its use produced a better stand of clover. At the station, on land producing 27 bu. of wheat per acre without fertilizers, the use of commercial fertilizers gave no appreciable increase. The application of nitrogen to old and exhausted wheat soils increased the protein in the grain from 1 to 3 per cent.

In the tests with corn, potash in three cases gave beneficial results, but insufficient to pay for its cost. Better results were secured from barnyard manure than from the commercial fertilizers.

From the one season's work no definite conclusions are drawn, but the results indicate that commercial fertilizers should not be used indiscriminately on old soils for the purpose of increasing the yield.

Some common weeds and their eradication, A. D. WILSON (*Minnesota Sta. Bul. 95, pp. 193-237, figs. 25*).—A general discussion on the methods of avoiding and eradicating weeds is given, with brief notes on the more common species.

At the station wild oats from the crop of 1905 were planted in September of that year and 70 per cent germinated. A large percentage of wild mustard and wild barley also germinated under the same treatment. It is pointed out that by facilitating the germination of these weeds in the fall they may be killed by frost and by subsequent cultivation. In another test 3 lbs. of rape seed sown per acre in cornfields at the last cultivation produced an excellent crop of rape and prevented the growth of pigeon grass or other weeds. Hemp sown thickly on a piece of ground infested with quack grass did not quite eradicate this weed. The use of 6½ gal. of kerosene per square rod was inefficient in destroying quack grass, and the same was true of the use of 80 bbls. of salt per acre. A 15 per cent solution of sulphuric acid, at the rate of 40 to 50 gal. per square rod, killed the plants, but this treatment is also too expensive to be practical. Covering the grass with tar paper apparently killed it, but this method, also, is too costly.

HORTICULTURE.

Horticultural work at the Canada experiment stations, W. T. MACOUN, W. S. BLAIR, S. A. BEDFORD, A. MACKAY, and T. A. SHARPE (*Canada Expt. Farms Rpts. 1905, pp. 91-116, 121-124, 302-309, 312-320, 346-355, 380-394, 415-438*).—The results of cultural experiments are reported with a large number of flowers, fruits, and vegetables grown on the experimental farms in Canada. The data are similar in character to those reported in previous years (E. S. R., 17, p. 139). Much miscellaneous information on the general work of each of the stations during the year is also included.

W. T. Macoun, at the central farm, reports the results of the examination of 30 seedling fruits of various kinds. Descriptions are given of 27 new or little-known varieties of apples in Ontario and Quebec. The net profits in the closely planted Wealthy apple orchard previously reported upon, amounted to \$103.13 per acre in 1905. This makes the average net profit since the orchard has been bearing over \$105.75 per acre, and since the orchard was started, \$59.03 per acre.

It will be remembered that the trees in this experiment are Wealthy and that they are set 10 ft. apart each way.

Some results of experimental shipments of apples to Glasgow in 1905 show that Wealthy apples brought the same price whether packing material was used or not. A table is given showing the yields of individual trees of Wealthy, McMahan, McIntosh, and Patten Greening apples for each of the years 1898 to 1905. Scions are being selected for propagation from the most productive trees. Twelve varieties of new black currants, originated from seedlings, are described, and a table given showing the results of a test of 50 varieties of strawberries.

Two new formulas are given for making kerosene emulsion. In one freshly slaked lime is used, and in the other flour. It is found that a perfect emulsion can be made by slaking one-half pound of good quicklime and emulsifying with 1 qt. of kerosene to 2 gal. of water from 3 to 5 minutes. It does not appear to be a matter of much moment whether the lime be dry and powdery when mixed with the kerosene or not, as kerosene emulsions have been made from both air slaked and freshly slaked lime, the lime being made into a thin cream with water before adding the kerosene. When flour was used it was found that 8 oz. was sufficient to hold in suspension 1 qt. of kerosene, and even 2 oz. would make a temporary emulsion for immediate use. If the flour was scalded before adding the kerosene, 2 oz. of flour was sufficient to make an emulsion that would stay up for more than a week. The flour emulsion is considered the more useful where it is not desired to discolor the trees on which it is used.

Some data are given of experiments in pruning tomatoes in the field, which indicate that earliness is considerably increased by pruning, and that the total yield is slightly greater from plants pruned once than from plants pruned twice. In fact, the total yield from plants pruned twice was not quite so great as from unpruned plants.

W. S. Blair, at the Nova Scotia station, found that in garden practice it is a decided advantage to stake even half tall varieties of peas and to plant two rows 6 in. apart, allowing 2 ft. space to the next row. This is much preferable to a single row 2.5 ft. apart, since about double the crop is secured. There is more difficulty in hoeing the double rows, and in field plantings it could not be practiced. Pods from the staked peas were much superior to the unstaked peas.

Tomato plants pinched back slightly did not give so large a yield as when not pinched back.

At the Manitoba station S. A. Bedford reports the fruiting of 2 varieties of standard apples, Hibernial and Duchess of Oldenburg. The Hibernial tree was root-grafted on Siberian crab in 1901, while the Duchess of Oldenburg was top-grafted on Siberian crab. Native Manitoba plums have been found much earlier than any of the other plums grown at the station, many of them ripening their fruit August 15.

In experiments in planting maple seed, a row 270 ft. long planted in the spring produced 2,600 trees, while rows of the same length, when planted in the fall, produced only 900 trees.

Report of the horticultural division of Mustiala Institute, 1894-1904. K. STENING (*Landtbr. Styr. Meddel.*, 51 (1905), pp. 73, pls. 22).—The report gives a brief account of the history of the division, with a description of the horticultural grounds of the institute, kinds of crops grown and value of different varieties, methods of culture, insect and fungus enemies, etc. A number of excellent half-tone reproductions of fruit trees and views of the grounds are included in the report.—F. W. WOLL.

Vegetable Growers' Association, Province of Ontario (*Ann. Rpt. Veg. Growers' Assoc. Ontario, 1 (1905), pp. 48*).—The history of the formation of the society, which occurred March 25, 1905, is noted, the constitution and by-laws of the association given, and the papers read before the association on a large number of subjects relating to vegetables and their culture.

The home vegetable garden, W. R. BEATTIE (*U. S. Dept. Agr., Farmers' Bul. 255, pp. 47, figs. 34*).—Some considerations are given on the location of the garden and its general arrangement, methods of preparing the soil, and the use of fertilizers, construction of hotbeds, seedbeds, etc., with detailed cultural directions for all the more common vegetables grown in the garden. The bulletin concludes with a planting table, in which the quantity of seed or number of plants required for 100 ft. of row, distance to plant, times for planting, and period required for the maturing of the crop are indicated.

The farmer's garden (*Bul. Maine Dept. Agr., 5 (1906), No. 1, pp. 42, fig. 1*).—Popular directions are given for the garden planting of fruits and vegetables, with a number of papers from growers in different sections of the State setting forth the value of the home garden.

Vegetable growing in Porto Rico, H. C. HENRICKSEN (*Porto Rico Sta. Bul. 7, pp. 58, pls. 10, figs. 2*).—Popular directions, based on the results of a season's work in which 6 plantings of vegetables were made 2 months apart, are given for a large number of vegetables. In general, it is shown that by proper cultural methods practically all the vegetables grown in temperate regions can be successfully grown at the station. The bulletin also contains a brief discussion of the principles of soil preparation and cultivation, the use of fertilizers and manures, the planting of seeds and the handling of seedlings, and the spraying of plants for the control of insect pests and fungus diseases.

Cucumbers, L. C. CORBETT (*U. S. Dept. Agr., Farmers' Bul. 254, pp. 30, figs. 14*).—Popular directions are given for growing cucumbers for early market in the open and in cold frames, growing cucumbers for pickling purposes, and for forcing cucumbers under glass. Treatment of the plants for the control of insect pests and fungus diseases is also considered.

The wild melon and the culture of melons in Central Asia, J. BARSACQ (*Jardin, 20 (1906), No. 466, pp. 213-216*).—In addition to a general discussion on melons in Central Asia, detailed observations are given on about 30 of the best known varieties, in which the time of maturity of each variety, average weight, quality, and keeping quality are considered.

Electricity as applied to agriculture (*Gard. Chron., 3. ser., 39 (1906), No. 1006, pp. 217, 218*).—It is stated that the effect of electricity on the growth of different cereals, fruits, and vegetables is being tested on an extensive scale at Pitchill and Bevington, in England.

In all 19 acres are being treated. Over this area high poles have been erected and from these, at a height of 16 ft., wires have been suspended. The electricity is discharged from these wires, the current being generated by a dynamo driven by a three-horsepower oil engine. Wheat and barley are the principal crops that are being grown, and a 25 per cent increase in yield is expected.

A case of persistent vitality in seeds, B. LANDRETH (*Proc. Amer. Phil. Soc., 45 (1906), No. 182, pp. 5-8*).—Seeds taken to Fort Conger, about 490 miles from the pole, by the Greeley expedition in 1883 were found in 1899 by the Peary party and sent to the United States, where they remained unplanted until the spring of 1905, when a package each of lettuce and radish seed were planted. The lettuce seed failed to germinate, but about one-half of the radish seeds grew to perfection and reproduced seed.

The Thays process for germinating seeds of maté, C. THAYS (*Jour. Agr. Trop.*, 6 (1906), No. 61, pp. 293-295).—The author has met with considerable success in germinating seeds of Paraguay tea (*Ilex paraguayensis*) by soaking in hot water, and gives results of a number of experimenters who have used this method. One man reporting on the subject states that when the seeds were placed in water at 80° C. and soaked for 6 hours, then the hot water renewed for a period of 4 days, a germination of 57 to 63 per cent was obtained.

The chemical composition of fruits, E. HOTTER (*Ztschr. Landw. Versuchsw. Österr.*, 9 (1906), No. 7, pp. 777-800).—Food constituents of the fruit and ash analyses are given for a large number of orchard and small fruits, including such fruits as elderberry, Japanese wineberry, mulberry, mountain ash, medlar, and all the usual fruits cultivated in garden and orchard. The article constitutes part 3 of an investigation on the marmalade industry, previously noted (E. S. R., 16, p. 689).

Specific requirements of new varieties in California fruit growing, E. J. WICKSON (*Pacific Rural Press*, 72 (1906), No. 3, pp. 36, 37).—The text of a paper presented at the convention of the American Association of Nurserymen at Dallas, Texas, is given.

California growers, shippers, and canners were consulted by means of circular letter, and the replies from 1,601 of these were used as a basis for the paper. It appears that 5 varieties of apples lead all others in California. These are the Yellow Newtown Pippin, Yellow Bellefleur, White Winter Pearmain, Grayenstein, and Red Astrachan. Of apricots Royal is decidedly in the lead. The same is true in the case of the Napoleon Bigarreau, a cherry locally known as Royal Ann. The Bartlett is of greater importance among the pears than all other varieties in California combined. The foremost of the California plums is Wickson. Eureka is the best variety of lemons grown, while Washington navel and Valencia are the best oranges.

The specific needs of fruit growers in the way of new varieties of each of these fruits, as well as of prunes, grapes, etc., are considered in detail.

Fruit division (*Rpt. Min. Agr. Canada, 1905*, pp. XVIII-XXI).—The text of the act relative to the packing and sale of Canadian fruits, with an account of the administration of the law during the year. The fruit of 811 packers, containing 212,348 packages, was inspected. Of this number 10,798 packages were actually inspected.

Dependable fruits, W. J. GREEN and F. H. BALLOU (*Ohio Sta. Circ.* 55, pp. 7).—A list is given of various orchard and small fruits which are most likely to succeed in different sections of the State.

Orchard culture, W. J. GREEN and F. H. BALLOU (*Ohio Sta. Bul.* 171, pp. 189-215, figs. 18).—Results are given of a comparative test, extending over a period of 6 years, of different methods of cultivating apple orchards.

On one plat of 40 Jonathan and Grimes trees the usual method of clean cultivation early in the season, followed by a fall cover crop, was observed. On a second plat clean cultivation was given throughout the season. On a third the trees were set in sod and the ground kept cultivated in a circular area 3 to 4 ft. in diameter about each tree. The grass between the trees was cut 3 or 4 times during the season and allowed to lie in place. On a fourth plat the trees were likewise set in sod, but were not cultivated. At the time of planting they were heavily mulched with straw. The grass between the trees was cut 2 or 3 times during the season, raked up and distributed around each tree as a mulch.

The plat which was given clean cultivation throughout the entire season washed so badly that this part of the experiment had to be discontinued at the end of the fourth season. Hence this method of cultivation is not recommended

for Ohio conditions. The average girth of the trees in each of the remaining plats and the average weight of apples secured are shown in the following table:

The growth and yield of apple trees by different methods of culture.

Method of culture.	Average girth of trees.	Average yield per plat.
Clean culture followed by—		
Cover crops	Inches. 9.71	Pounds. 22
Sod culture	8.55	7
Sod and mulch	10.56	43

The table brings out the fact that the best results, as regards both growth and yield of fruit, have been obtained by the sod-mulch method of culture.

It has been claimed that in orchards receiving clean cultivation early in the season, followed by a cover crop, the root system develops to a greater depth and is consequently less injured by drought, heat, and cold than by the mulch system. The authors examined numerous cubic-foot areas of soil from the different plats with reference to development of roots, examining first a 2-in. layer, then the next 4 in., and finally the bottom 6 in., separately. "The main root systems of apple trees, under the different methods of culture, were found to be at a surprisingly uniform depth, the greater portion of the roots, both large and minute, being removed with the upper 6 in. of soil."

On the plat given clean culture, followed by cover crops, it was found that thousands of feeding rootlets penetrate upward to the very surface of the soil, where they actually come in contact with cultivator or harrow, while but very few of these rootlets penetrate to the lower, more compact, colder soils. Each season these feeding rootlets are cleanly pruned away by the plowshare, without apparent injury to the trees or crops, since they have performed their function and their places are occupied the succeeding season by a new generation.

A very dense network of feeding rootlets was also found on the surface of the soil beneath the heavily mulched trees. These rootlets also penetrate the lower layers of the mulch itself. There appeared to be, however, fully as many feeding rootlets in the upper 6 in. of the soil itself as was the case when the soil was given clean cultivation throughout the early part of the season. It is held, therefore, that since the main root system forms at as great a depth under the mulch system as when the crop is given clean cultivation, and since the feeding rootlets are just as numerous in the soil itself, the removal of the mulch, or even a change from heavy mulching to the clean culture cover-crop plan, would not be as disastrous as has been generally supposed. The destruction of the surface rootlets and of those that penetrate the mulch, either by cold, drought, or heat, is therefore no more serious a matter than is the destruction of the rootlets in the clean cultivated soil by the plow.

The authors state that "under the 'sod-mulch system' of culture the trees have uniformly made a heavier, more vigorous growth than under any other system of culture. This is no doubt due to the certainty and uniformity of the generous store of fertility right at hand—the concentration of an abundance of plant food where it is most available and the consequent presentation of conditions, beneath the mulch of vegetable matter, especially favorable to a healthy, unstinted, continuous nourishment of the trees."

Cover crops for young orchards, R. A. EMERSON (*Nebraska Sta. Bul. 92, pp. 1-23, pls. 2, figs. 8*).—A summary is here given of experiments which have been carried on since 1899 in the use of cover crops in young orchards. Part of the data here given have been previously noted (*E. S. R., 14, p. 1066*).

The author shows that the factor of first importance in protection against winter injury is the securing of hardy varieties; second, the selection of a comparatively high site for the orchard; and, third, the use of cover crops, which dry out the soil early in the fall and induce early maturity. In the State of Nebraska cover crops must be considered primarily from the standpoint of their effect on the soil moisture, rather than from their fertilizing value.

The author thus sums up the requirements of an ideal orchard cover crop for Nebraska: "It should start growth promptly in order to insure an even stand and to choke out weeds. It should grow vigorously to insure a heavy winter cover and to dry the ground in case of late-growing trees, so as to hasten their maturity. It should be killed by the early frosts so that it will stop drying the ground after danger of late tree growth is passed, and to help conserve our light fall rains, so much needed by the trees in winter. . . . A cover crop should be heavy enough to furnish as good direct protection as possible against freezing and thawing of the ground, and it should stand sufficiently erect to hold snow against the power of strong winds. . . . Finally, in case of poor soils or of old and feeble trees, the cover crop should be a leguminous one, in order that it may add to the store of nitrogen in the soil, and thereby increase the vigor of growth of the trees."

This excludes from use such crops as rye, winter wheat, vetches, and clovers which live over winter, and late-growing crops, like field peas, rape, oats, and barley. Of the crops killed by early frosts the most satisfactory have been corn, cane, and millet. These crops start promptly into growth in midsummer, choke out the weeds, dry out the ground, and make an erect winter cover which holds the snow fairly well. In dry falls, corn makes a poorer growth than cane or millet.

"Millet makes a good cover if it can get six weeks of growth before frost. It stands nearly erect and thus holds the snow well, and is so leafy that it affords fair winter protection even without snow."

A number of tables are given showing the effect of various cover crops on soil and moisture in both the spring and fall, on the depth to which the ground is frozen underneath them, and their effectiveness in holding snow. Crops which stand erect catch the snow and hold it, and the ground freezes to a less depth underneath than crops which mat down. A good covering of snow is one of the most effective means of preventing alternate freezing and thawing of the ground, and also prevents the ground from freezing so deeply.

Picking, packing, and marketing the apple, L. B. JUDSON (*Idaho Sta. Bul.* 54, pp. 37, pls. 17).—Popular directions are given for the harvesting, picking, and marketing of apples, including an account of packing houses and fittings, and directions for organizing fruit growers into associations to secure better packs and higher prices. The appendix contains a circular of advice to growers and packers distributed among the members of the Hood River Apple Growers' Union, the text of the Canadian Fruit Marks Act of 1901, and the articles of incorporation and by-laws of the Hood River Fruit Growers' Union.

Relative to the time of harvesting apples, the author calls special attention to the necessity of harvesting Jonathan apples when the seeds have turned a light brown. If the fruit is not picked until well colored and the seeds are dark around the edges, it is likely to rot at the core while still sound on the outside.

Orange cultivation in the Khasi hills, B. C. BASU (*Agr. Jour. India*, 1 (1906), No. 1, pp. 62-67).—About 100 square miles of the Khasi hills are suitable for orange cultivation. The oranges grown are known to the world as the Sylhet oranges, and are produced entirely from seedlings, which bear at the end of about 7 years. The general methods of culture are given in detail.

A Louisiana plant breeder, J. L. NORMAN (*Nat. Nurseryman*, 14 (1906), No. 6, pp. 183, 184, fig. 1).—The author describes his method of breeding hardy oranges and the umbrella mulberry originated by him.

The wild apricot or wild peach (*Transvaal Agr. Jour.*, 4 (1906), No. 15, p. 617, pl. 1).—A colored plate is given of the fruit of *Landolphia capensis*, commonly called the wild apricot or wild peach. The fruits are edible, with a pleasant acid flavor, and are said to make good jelly, brandy, and vinegar.

The dried banana, P. AMMANN (*Agr. Prat. Pays Chauds*, 6 (1906), No. 38, pp. 381-389, figs. 4).—A discussion of the commercial future of dried bananas, with the results of experiments in drying bananas with two different forms of evaporating machines.

It appears that there is a loss in peeling bananas of about 35 per cent of their original weight. In one experiment 5 kg. of peeled bananas gave 1.5 kg. of dried bananas, and in another 1.38 kg. A larger portion of dried bananas was obtained from the use of mature fruit than from slightly green or overripe fruit. Analyses are given of two samples of banana flour.

Statistics on the German fruit industry (*Jahrb. Deut. Landw. Gesell.*, 20 (1905), pp. 142-164).—Statistics are given showing the acreage and number of the different kinds of orchard fruit trees in various provinces of Germany.

Fertilizer experiments with cacao, L. STRUNK (*Tropenpflanzer*, 10 (1906), No. 8, pp. 516-535).—A number of different fertilizers and combinations were used on cacao. The heaviest yield of unfermented fruit was obtained on a plat in which each tree was fertilized with 1,000 gm. kainit, 480 gm. superphosphate, and 240 gm. sulphate of ammonia. When 1,000 gm. of slaked lime were used instead of superphosphate in the formula, or when the sulphate of ammonia was omitted entirely, the yields were about 12 per cent less. The details of the experiment are given for each plat monthly from April to November in tabular form, with the analyses of the soil on which the experiment was conducted.

The grape trellis, T. V. MUNSON (*Texas Farm and Ranch*, 25 (1906), No. 32, p. 2, figs. 2).—The author describes an improvement of what is known as the Munson three-wire canopy trellis, giving illustrations. The improvement consists primarily in the methods of tying on the cross pieces of the posts, and in grounding the wires to prevent injury to the fruit from lightning.

How to make a fruit garden, S. W. FLETCHER (*New York: Doubleday, Page & Co.*, 1906, pp. XIX+283, pl. 1, figs. 190).—This book contains popular directions for the planting and care of all of the common orchard and small fruits, including subtropical fruits, and for the harvesting and storage of the same. Methods of treating insect pests and fungus diseases and varieties especially adapted to the home garden in each of the different States are considered. The appendix contains numerous formulas relative to spraying material, grafting wax, rules for the exhibition of fruits, etc. Many new illustrations add greatly to the value of the work, which is intended primarily for the amateur in fruit growing.

Common sense gardens, C. V. V. SEWELL (*New York: Grafton Press*, 1906, pp. 396, pls. 72, figs. 23).—The author discusses methods of laying out home grounds and of planting them. The merits of various trees, shrubs, and flowering plants for ornamental purposes are considered in detail, as well as such matters as walks, walls, water, and the harmonious arrangement of all of these with the home.

Carnations, picotees, and pinks, H. W. WEGUELIN (*London: W. H. & L. Colingridge*, 2. ed., rev., pp. VIII+104, pls. 7, figs. 24).—This work is devoted primarily to the culture of these flowers outdoors.

FORESTRY.

On the rate of growth and yield of forests in Västerbotten County, Sweden, G. BERONIUS (*Skogsvårdsför. Tidskr.*, 4 (1906), No. 1, pp. 1-15, map 1, *dgms.* 2).—The author finds that the percentage increment of the pine and spruce forests in this region of about 25,000 hectares amounts to 1.9 per cent or 1.03 cubic meters per hectare, ranging from 2.7 to 1.3 per cent for the different types of forest. The total yield is calculated to be on an average 0.96 cubic meter per hectare of productive area or over 16,000 cubic meters for the forests surveyed.—F. W. WOLL.

Observations on afforesting moor lands, H. LIECHTI (*Schweiz. Ztschr. Forstw.*, 57 (1906), No. 5, pp. 141-151, pls. 2, figs. 5).—The successful afforestation of moor lands with spruce, pine, etc., is described and illustrated.

Deforestation in China, B. WILLIS (*Proc. Soc. Amer. Foresters*, 1 (1906), No. 3, pp. 141-146, pl. 1).—A discussion of the general forest situation in China with special reference to the deforested regions in northern China.

Growing locust in Hungaria, A. GASKILL (*Forestry Quart.*, 4 (1906), No. 4, pp. 106-111).—The author studied the methods of growing locust in the forests lying in the Great Danube plain about 100 miles south of Budapest where conditions seem to be somewhat similar to those found in the eastern part of our plains region. A money return of about 2½ per cent on land valued at \$20 per acre is secured. Tables are given showing the stands of seedling and second growth locust on sample plats of 1 acre each and of the yield of locust sprout forests of the first, third, and fourth classes.

Rocky Mountain seedling growth, J. C. BLUMER (*Forestry Quart.*, 4 (1906), No. 2, pp. 98-105).—A number of observations on the reproduction of forest trees in the Pike's Peak Forest Reserve were made.

The principal species of trees in this district are conifers, and of these, bull pine, red fir, limber pine, and Engelmann spruce are most numerous. The seed of all these species needs bare mineral soil on which to germinate. Attention is called to the great density required for natural pruning in the Engelmann spruce. "Trees 3 or 4 in. in diameter, 15 to 20 ft. high, and 40 years old, must usually stand not over 1 ft. apart in order to lose their branches up to 3 or 4 ft. from the base."

Germination period of some conifers, E. ZEDERBAUER (*Centbl. Gesam. Forstw.*, 32 (1906), No. 7, pp. 366-315).—A large number of tests were made of the time required for germination of seeds of different species of conifers. With most of the species of *Picea*, *Pinus*, *Larix*, *Tsuga*, *Sequoia*, *Douglasii*, *Cryptomeria*, and *Cupressus*, the period of germination varied from 14 to 28 days, and of *Pinus strobus* from 30 to 40 days after placing in the germination apparatus.

Germination tests and valuation of pine seeds, HAACK (*Ztschr. Forst u. Jagdw.*, 38 (1906), No. 7, pp. 441-475, pl. 1).—In continuation of previous work (E. S. R., 17, p. 370) the author made extensive investigations to determine (1) how the various forms of pine seedlings which appear in germination tests are to be judged with reference to the value of the sampled seed, (2) the influence of light on the germination of pine seed, (3) the relation between laboratory tests and the percentage germination actually obtained under field conditions, and (4) the effect of different degrees of temperature and different amounts of moisture on the germination of pine seed.

It was found in the first place that many seeds which germinate should not be counted as such in germination tests because the germs are so weak that they never produce plants. Illustrations are given showing many of these weak

seedlings. For the larger percentage of pine seeds the optimum germination temperature is 24° C. The total percentage of germination, as well as the energy of germination, was less in darkness than in light. The poorest results were secured with blue light, while yellow light stood next to daylight in value. The strength of the light also had considerable influence.

Seed which gave 95 per cent germination in the laboratory gave but 39 per cent under unfavorable conditions out of doors, and seed which gave 60 per cent germination in the laboratory gave but 3 per cent germination out of doors, showing that the difference observed in germination tests in the laboratory is not a measure of their relative values for out of door planting. It was also found that the seed which germinated with greatest energy under favorable conditions produced more plants when sown out of doors than seed which gave the same percentage of germination but were not so vigorous.

The data secured in drying seeds at different degrees of temperature and in atmospheres saturated to different degrees of moisture correspond closely to that previously reported (E. S. R., 17, p. 370). Seed held at a temperature of 80° C. in an atmosphere saturated with 59 gm. of water per cubic meter were not noticeably injured. Seed dried in an atmosphere containing from 90 to 105 gm. per cubic meter were injured in a temperature of 56° C. When the moisture was raised to 190 to 296 gm. per cubic meter the seed was entirely killed, which, when dried in an atmosphere containing 59 gm. per cubic meter was not injured.

The life history of *Pinus sylvestris*, A. W. BORTHWICK (*Trans. Roy. Eng. Arbor. Soc.*, 6 (1905-6), pt. 2, pp. 205-223, pls. 4).—A monograph on the Scotch pine, including an account of the fungus insects affecting it.

***Ficus elastica*, its natural growth and artificial propagation, E. M. COVENTRY** (*Calcutta: Gort.*, 1906, pp. VI + 35, pls. 3).—This bulletin embodies primarily what has been learned in Assam regarding the growing of *Ficus elastica*. Account is given of the methods of culture and preparation of the rubber for market.

The science of para rubber cultivation, H. WRIGHT (*India Rubber Jour.*, n. ser., 32 (1906), No. 3, pp. 140-144).—A paper on this subject, read before the Kegalla Planters' Association in Ceylon, with the discussion following.

A compilation of notes on India rubber and gutta-percha, G. P. AHERN ([*Philippine*] *Bur. Forestry Bul.* 3, pp. 40, figs. 2, map 1).—A large amount of material relative to the culture, preparation, and uses of Ceara, Castilloa, and Para rubber is here brought together.

Experiments with rubber-yielding plants in Dominica, J. JONES (*West Indian Bul.*, 7 (1906), No. 1, pp. 16-20, figs. 3).—The results secured at the botanic station in growing and tapping *Castilloa elastica* and *Funtumia elastica* are reported upon. The results indicate that Castilloa is more wind resistant and less subject to injury than Funtumia, and therefore better suited to culture in the island.

Rubber experiments in St. Lucia, J. C. MOORE (*West Indian Bul.*, 7 (1906), No. 1, pp. 21-29, figs. 3).—Some data are given on tapping experiments with *Castilloa elastica*. The trees were 15 to 17 years old and the average yield of rubber obtained was 11.66 oz. per tree.

What are the essentials of a State fire law? E. A. STERLING (*Proc. Soc. Amer. Foresters*, 1 (1906), No. 3, pp. 132-140).—A paper on this subject delivered before the society in 1904.

The creosoting of home-grown timber, W. B. HAVELOCK (*Agr. Students' Gaz.*, n. ser., 13 (1906), No. 1, pp. 13-16).—A table is given showing the results of tests to ascertain the absorption of creosote oil under high pressure by 56 kinds of timber.

The timber was sawn to different sizes, seasoned in the open air, and the oil injected under a pressure of 80 to 85 lbs. per square inch for 3 hours. The creosote was warmed by steam during use and a vacuum of 9 lbs. was obtained in the cylinder before the oil was injected. The table shows the absorption of creosote per cubic foot of the wood impregnated.

Big returns from growing trees, F. BURNS (*Farming, 1 (1906), No. 5, pp. 176, 177, figs. 6*).—Financial statements are given of results obtained from a well-managed woodlot in Pennsylvania and of another in Nebraska.

DISEASES OF PLANTS.

New and little-known plant diseases in Nebraska, F. D. HEALD (*Abstr. in Science, n. ser., 23 (1906), No. 590, p. 624*).—Notes are given on the following diseases:

(1) Twig-girdle of the apple due to a Phoma-like fungus. (2) Trunk rot of the cherry due to *Schizophyllum commune*. A small orchard of trees 5 to 6 years old was completely destroyed by this fungus. (3) Wheat leaf fungus (*Leptosphaeria tritici*). Among other things, its distribution over the same area as the Hessian fly was noted. (4) Bacterial leaf blight of wheat. A bacterial blight of the leaves was common on the leaves of wheat in the breeding plat at the experiment station and was also observed elsewhere. (5) Bacterial blight of soy bean. This disease was quite serious on soy beans used as an orchard cover crop at the experiment station. (6) Moldy corn due to a fungus provisionally referred to *Diplodia maydis*, but differing in several points in habit and structure.

Report of the consulting botanist, W. CARRUTHERS (*Jour. Roy. Agr. Soc. England, 66 (1905), pp. 162-173, figs. 2*).—After brief accounts of the purity and germination of clover and grass seeds and the enumeration of species of poisonous and troublesome weeds, the author describes a number of diseases of plants which were observed during the year.

The principal of these were diseases of potatoes, and the observations are briefly summarized regarding the *Nectria solani*, potato scab, potato canker hitherto ascribed to *Chrysophlyctis endobiotica*, a wart disease, the early blight caused by *Macrosporium solani*, and two bacterial diseases of potatoes, one attributed to *Bacillus solaniperda*, the other to *B. phytophthorus*. Recent observations place the fungus *Chrysophlyctis* with *Oedomyces*. Notes are given on a number of other miscellaneous diseases.

The rusts of Australia, D. McALPINE (*Melbourne: Dept. Agr. Victoria, 1906, pp. VIII + 349, pls. 55, figs. 28*).—This publication treats of the structure, nature, and classification of the rusts of Australia, all the species known to occur being included in the book. Those which are not native to the country are specially designated, and all the species are figured so far as specimens were available.

This monograph is preliminary to a study of methods of preventing the appearance or limiting the spread of rusts on numerous commercial crops. The first part treats of the different stages of the rusts and their relation to the host plants and to other fungi, and a chapter is devoted to the present position of rust in relation to wheat production in Australia. In the second part of the book classifications and technical descriptions are given of the different species. An extensive bibliography of literature completes the work.

Infection of plants by rust fungi, W. L. BALLS (*New Phytol., 4 (1905), No. 1, pp. 18, 19*).—The author notes having observed that the germ-tubes of spores on infected leaves radiated from the spore if the surrounding atmosphere was kept well saturated, and this suggested that water vapor might be the body in search of which the fungus entered the stomata.

In another publication (E. S. R., 16, p. 885) it has been shown that the first entrance of the germ-tube was probably due to some positively chemotropic body which is common to all plants. To determine the identity of this substance the author tested the germination of spores placed on a membrane of thin rubber, perforated with holes comparable in size with stomata. This membrane was arranged with one side exposed to air saturated with water vapor and the other to the air of the laboratory. On the latter side spores of *Puccinia glumarum hordei* were sown, and after 2 days the membranes were microscopically examined and the germ-tubes were found entering the majority of these artificial stomata.

It is believed that other circumstances may possibly share in attracting the germ-tube to the stomata of the plant, but the attraction of the water vapor is believed to account for the first entrance of the germ-tube.

Smut in wheat, barley, and oats, and how to prevent it, I. B. P. EVANS (*Transvaal Agr. Jour.*, 4 (1906), No. 14, pp. 389-396, pl. 1).—The author reports on the abundance of smut in wheat, barley, and oats in the Transvaal, and describes the copper sulphate, hot water, and formalin methods of treatment for its prevention.

Smut treatment, A. MACKAY (*Canada Expt. Farms Rpts.* 1905, p. 364).—Attention is called to the serious loss due to the presence of the bunt or stinking smut of wheat, and the author recommends the treatment of the seed wheat with solutions of formalin or copper sulphate before seeding. Formalin solutions are also recommended for the treatment of seed oats and barley.

Preventives of smut in wheat, S. A. BEDFORD (*Canada Expt. Farms Rpts.* 1905, pp. 324, 325).—According to the author, about 6 per cent of the wheat received at Winnipeg during the past year was rejected by the inspectors on account of the large amount of smut prevalent.

Attention is called to the desirability of treating seed, and the results of treating seed with formalin and copper sulphate are shown. In the experiments reported different lots of seed wheat were sprinkled and soaked with solutions of formalin and copper sulphate and the resulting crop was entirely free from smut, although the untreated wheat contained more than 12 per cent smutted heads. The increase in yield attributed to the treatment was from 2 to 5 bu. per acre on the different plots.

Notes on brusone, U. BRIZI (*Agr. Mod.*, 11 (1905), pp. 380, 394, 452; *abs. in Centbl. Bakt. [etc.]*, 2. Abt., 15 (1906), No. 21, pp. 653, 654).—A study is given of brusone or smut of rice, in which the author reviews various theories regarding its cause and gives the results of his own investigations regarding it.

Voglino is said to have considered it primarily due to bacteria attacking the plants from the soil, while Ferraris and Farneti consider *Piricularia oryza* the cause of the disease. According to the author the injury to the plant is first shown on the finest rootlets, a fact which apparently escaped all previous investigators except Voglino (E. S. R., 15, p. 590).

The first indication of the disease may be seen in the browning of the parenchymatous tissues of the finest roots, followed by the discoloration of the epiblem and the central cylinder and later by the destruction of the protoplasm in the parenchyma cells. The appearance of the disease on the aerial parts of the plant follows after a considerable interval. If rice is grown in poorly aerated water cultures, typical brusone will develop on the roots, stems, and leaves within a few days, but the author takes this as an indication that the disease is not of parasitic origin, but that it results from the destruction of the roots in a poorly aerated soil. The disease is always worst in heavy soils accompanied with a high temperature.

For the prevention of the disease the author recommends the frequent changing of the water on the fields and deep stirring of the soil whenever possible.

While the disease is believed to be primarily due to constitutional causes, yet the uniform occurrence of organisms seems to indicate that it is greatly complicated by their activity.

On the stages of development reached by certain biologic forms of *Erysiphe* in cases of noninfection, E. S. SALMON (*New Phytol.*, 4 (1905), No. 9, pp. 217-222, pl. 1).—Experiments were carried on with a number of biologic forms of *Erysiphe graminis*, and it was determined that the failure of the conidia to infect certain host species is to be attributed not to the failure of the germ-tube to penetrate the leaf cells of the plant, but to the inability of the fungus to develop the haustorium which is formed, or to the incapacity of the fully formed haustorium to adapt itself to the intracellular conditions.

A fungus disease of alfalfa in England, E. S. SALMON (*Gard. Chron.*, 3. ser., 39 (1906), No. 1000, pp. 122, 123; *Jour. Bd. Agr.* [London], 13 (1906), No. 1, pp. 51, 52).—A report is given of diseased alfalfa plants which showed several superficial, warted, gall-like outgrowths, about $\frac{3}{4}$ in. across, found at the crown of the roots.

These galls, upon examination, proved to be due to attacks of *Vrothlyctis alfalfa*. From the appearance of the plants it was evident that they had been infested for some time, and some of the plants were almost dead. This is the first report of the fungus in England. It was first observed in Ecuador in 1892, and later reported as occurring in Germany (E. S. R., 14, p. 773). A detailed account of the disease and the results of investigations on the fungus are promised at some future time.

Potato scurf and potato scab, H. T. GÜSSOW (*Jour. Roy. Agr. Soc. England*, 66 (1905), pp. 173-177, fig. 1).—An account is given of a peculiar scabbed condition of potatoes which upon investigation was found to be due to *Rhizoctonia solani*. A comparison of descriptions of *R. violacea* and *R. solani* shows no morphological differences, and from the identity of the mycelium on alfalfa and on the potato there appears to be no doubt that these two species are identical. In this case *R. solani* must be considered as a synonym of *R. violacea*.

The author states that the scurf appearing on the potatoes does little injury to them either as an article of food or for use as seed, but when the disease progresses further so as to result in a scab-like form, while the food value of the potato is not affected, such tubers should in no case be used as seed. The so-called deep scab was found to be a stage of this disease, and tubers affected by this have little value as food and under no circumstances should be used as seed.

Bacterial wilt of tobacco, Y. UYEDA (*Bul. Imp. Cent. Agr. Expt. Sta. Japan*, 1 (1905), No. 1, pp. 39-57, pls. 5).—For 20 years or more there has been known in Japan a disease of tobacco variously designated as tobacco wilt, root rot, or black shank. The disease has been under the author's observation for about 5 years and has been determined to be of bacterial origin. In many ways it resembles the wilt of the eggplant and tomato, but the organisms are not identical.

The disease may attack the young as well as the full-grown plants any time from June to September. The affected plants wilt, the leaves become yellow, the stems are blackened, and the entire root system is destroyed. The bacteria gain entrance through the root hairs, stomata, and wounds, and inoculation experiments show that the disease can be readily transferred to sound plants, either by the transfer of the plant juices or by the use of pure cultures of the organism. In affected plants the bacteria are first noticed in the fibrovascular bundles of the stems and leaves, which soon become blackened. Later the darkening extends to the larger veins of the leaves and adjacent tissues.

The morphological and physiological characters of the organism are described at length and comparisons are drawn between the cause of this disease, which is given the name *Bacillus nicotiana* n. sp., and a number of other bacteria which cause diseases of plants, especially *B. solanacearum*. The bacillus is found to attack many cultivated varieties of tobacco, although some have thus far escaped, as does *Nicotiana rustica*. Inoculation experiments have shown that positive results were obtained with pure cultures on *Physalis minimum*, *Capsicum longum*, *Polygonum tinctorium*, and *Amarantus gangeticus*, but failed with egg-plants, tomatoes, and *Physalis alkkekengi*.

Early planting and resistant varieties are the preventive means suggested. The author recommends in practice the burning of all trash and affected plants and care in the use of fertilizers, nitrogenous fertilizers tending to predispose the plants to the disease while potash fertilizers do not.

Tomatoes and their diseases, W. W. FROGGATT (*Agr. Gaz. N. S. Wales*, 17 (1906), No. 3, pp. 209-218, figs. 6).—After a brief account of the culture of tomatoes, the author mentions some of their insect and fungus enemies. The insects mentioned are the bollworm (*Heliothis armiger*) and the Rutherglen bug (*Nysius vinitor*). Among the diseases described are the rosette of tomatoes, a curious malformation of young fruits to which the name "sheath calyx" is given: sleepy disease, due to *Fusarium lycopersici*; black rot, caused by *Macrosporium tomato*; pimply rot; leaf rust, due to *Cladosporium fulvum*, and leaf blight, caused by *Septoria lycopersica*. Where known, methods of treatment for the prevention of these diseases are given.

The parasitism of Neocosmospora, H. S. REED (*Science*, n. ser., 23 (1906), No. 593, pp. 751, 752).—The author reports having found in ginseng gardens in Missouri in 1904 a wilt disease which is attributed to *Neocosmospora vasinfecta* var. *nivea*. The fungus has been studied and described in a bulletin of the Missouri Experiment Station (E. S. R., 17, p. 1164), and in the present article the author calls attention to some features in the parasitism of the fungus.

The fungus is generally believed to be an active parasite, but the results of the author's studies seem to confirm the claim of Atkinson (E. S. R., 4, p. 831) that it is a weak parasite and only attacks plants which are first weakened by the presence of some other fungus. This conclusion is based on the facts that the wilt disease did not appear except on ginseng plants previously attacked by anthracnose, that spraying the plants for the prevention of anthracnose was followed by freedom from wilt, and that watermelons grown in sterilized soils that received test-tube cultures of the organism failed to show the slightest indication of the wilt disease. The author believes that in previous investigations where active parasitism of *Neocosmospora* was claimed the soil was not sterilized, and that, so far as his experiments go, the form isolated from the ginseng plant is not an active parasite.

Some fungus diseases and their treatment, B. F. FLOYD (*Missouri Sta. Circ. Inform.* 21, pp. 12).—Brief descriptions are given of a number of fungus diseases of various fruits, berries, vegetables, and ornamental plants, and, so far as known, suggestions are given for their treatment.

Pear blight work and its control in California, M. B. WAITE and R. E. SMITH (*Cal. Fruit Grower*, 33 (1906), No. 923, pp. 1, 3-6, 9, 12-15, figs. 2).—A review is given of the work carried on in the State.

Investigations on grape anthracnose, P. VIALA and P. PACOTTET (*Rev. Vit.*, 24 (1905), Nos. 618, pp. 433-439, figs. 7; 620, pp. 489-496, figs. 15; 621, pp. 517-523, figs. 3; 623, pp. 573-580, figs. 13; 624, pp. 601-608, figs. 5; 626, pp. 657-663, pls. 6, figs 8; 25 (1906), Nos. 632, pp. 89-91, figs. 4; 641, pp. 341-347, figs. 14; 642, pp. 369-375, figs. 17).—The results of studies on the fungus *Man-*

ginia ampelina or *Sphaelotoma ampelium*, the cause of the grape anthracnose, are given.

The various forms of reproduction are figured and described, especial attention being given to the morphology and biology of the organism. Attention is called to the fact that the disease can not be controlled by a single winter treatment of the vines with a strong solution of iron sulphate, as it does not fully penetrate the sclerotia. Two applications at intervals of 15 days will be found more efficient, but even this treatment will not wholly prevent the disease.

Notes are also given on the anthracnose of peas and of plane trees due, respectively, to *Gliosporium verrisequum* and *G. lindemuthianum* or, as it is more frequently called, *Colletotrichum lindemuthianum*. By the same methods of study as those pursued in the investigations of the grape anthracnose, the authors found the same kinds of organs of reproduction, namely, spermagonia, pycnidia, cysts, yeast-like bodies, conidia, etc., and their development differed only in individual particulars.

Hints on the treatment of grape mildew, L. DEGRULLY (*Prog. Agr. et Vit. (Ed. l'Est)*, 27 (1906), No. 15, pp. 429-433).—Attention is called to the advisability of early and thorough spraying for the prevention of the downy mildew of grapes, and formulas are given for the preparation of different fungicides, together with directions for their application.

Report on experiments for the control of mildew in 1905, E. CHUARD, H. FAES, and F. PORCHET (*Chron. Agr. Vaud.*, 19 (1906), Nos. 6, pp. 145-153; 7, pp. 181-189; 8, pp. 226-235; and 9, pp. 270-274).—An account is given of some cooperative experiments on the control of grape mildew by the use of fungicides. This work was begun in 1903 and continued in 1904 and 1905, and the present report is based very largely upon the results obtained in 1905.

In the investigations it was found that the mildew made its appearance earlier than usually reported, on which account the first application of the fungicide should be advanced beyond the date generally recommended, namely, June 15. In the vineyards treated 6 reported perfectly satisfactory results; in 3 others the results were less satisfactory, but an analysis of the reports indicates that the treatment was not strictly in accordance with the recommendations given.

All the reports show that the fungicides which were used, consisting of Bordeaux mixture, soda Bordeaux, and copper acetate solutions, need not be used in strengths greater than 2 per cent, these being as efficient as those used in greater concentration. For the first application not less than 600 liters per hectare should be employed, to be followed by 3 or 4 applications at the rate of 1,100 to 1,200 liters per hectare. The time intervening between the applications should not exceed 20 days during years favorable for the development of the fungus.

Smut of cultivated bamboo, S. HORI (*Bul. Imp. Cent. Agr. Expt. Sta. Japan*, 1 (1905), No. 1, pp. 73-89, pls. 4).—The author notes having received in 1904 specimens of the large bamboo (*Phyllostachys puberula*) that were affected with a smut. The disease always occurs on the younger internodes and growing portions of the branches, and apparently it may appear whenever the surrounding conditions are favorable, from the time the spring buds open until the growth of the branches ceases. Such diseased branches seem generally to stop further growth, and finally the entire plant is destroyed.

The smut has been found on several kinds of bamboo, both cultivated and wild, but where the large bamboo is extensively cultivated it seems to be confined to that species. At present it is known to occur on 4 species, namely, *Phyllostachys bambusoides*, *P. puberula*, *Sasa ramosa*, and *Arundinaria simoni chino*.

The characters of the fungus are described at considerable length, and as a result of the author's studies he determines it as probably identical with *Ustilago shiraiana*, an amended description of which is given.

As preventive measures it is recommended that smutted branches be cut off and burned before the spore masses mature and the spores are scattered, and the removal of wild species in regions where the large bamboo is extensively cultivated. It is believed that spraying with Bordeaux mixture at the time the spring buds are developing would prove beneficial.

The wilt disease of pigeon pea and pepper, E. J. BUTLER (*Agr. Jour. India*, 1 (1906), No. 1, pp. 25-36, pls. 5).—A description is given of wilt diseases of the pigeon pea (*Cajanus indicus*) and of the cultivated black pepper.

The pigeon pea wilt is found over a wide extent of India and in some regions is of serious consequence. The plants are attacked here and there over the field, and when a period of hot dry weather occurs large areas appear suddenly infected. The practice in growing this crop in India is to ratoon the fields, and in these the fungus spreads so that in some instances all plants are killed.

An examination of the diseased plants showed the presence of a fungus which the author has determined as a species of *Nectria*, and inoculation experiments have shown in a considerable proportion of the trials that the disease is due to some of the stages of this organism, 3 of which are described at some length.

In the account regarding the pepper vine wilt, the author states that the serious destruction of the plants in some regions threatens the industry. In many instances it was found that the wilted plants were affected by nematodes (*Heterodera radicolu*), but the uniformity of the symptoms of the disease seemed to indicate that some other cause than the nematodes must be ascribed to it, and evidence is presented which the author believes warrants the statement that it is due to a species of *Nectria*. The symptoms of the disease are described, and it appears that while the nematodes may contribute to the destruction, the primary cause is to be attributed to the fungus.

In conclusion the author enumerates a number of species of plants that are subject to wilt diseases, about 1 dozen cultivated crops being more or less subject to damage from this cause.

Tree root rot (*Jour. Bd. Agr. [London]*, 13 (1906), No. 2, pp. 111-114, fig. 1).—A root rot of trees, due to *Armillaria mellea* or *Agaricus melleus*, is described, and it is stated that nearly all kinds of orchard and deciduous trees are subject to its attack as well as many coniferous trees.

Usually the first indication of disease is to be observed in the drooping and yellowing of the foliage, and when these symptoms appear the presence of a thin firm white sheet of mycelium situated between the bark and the wood about the collar of the plant or on the main root branches indicates that this fungus is the cause of the trouble. Later this mycelium extends up the trunk of the tree and changes into black cord-like strands of mycelium, known as rhizomorphs.

When trees are found affected a portion of the bark at the collar should be removed and if the mycelium is found to have grown up the trunk the best course to be recommended is to cut down the tree, removing as much as possible of the root, which should be burned. If the mycelium has not ascended the trunk but is confined to certain branches of the root they should be removed and as much as possible of the root exposed and covered with a mixture of lime and sulphur. When the toadstool forms appear at the base of the trunk they should be collected and burned.

A canker of the yellow birch, J. B. POLLOCK (*Rpt. Mich. Acad. Sci.*, 7 (1905), pp. 55, 56).—A brief description is given of a canker observed on branches and

twigs of yellow birch. This canker not only causes the disfiguration of the tree, but seriously interferes with its growth by cutting off the channels of water and reserve transportation.

An examination showed that the canker was due to a species of *Nectria* which agrees fairly well with *Nectria coccinea*, although differing from the descriptions usually given. A modified technical description of the fungus is presented, and while there is no experimental proof of its parasitism, it is concluded that the canker of the yellow birch is due to this fungus. The disease is local in its attack, not spreading from a given point of infection but through new inoculations. The point of infection is usually the base of a dead lateral twig, and the cause is probably due to a wound parasite.

The Novar system of combating larch disease (*Jour. Bd. Agr. [London]*, 12 (1906), No. 12, pp. 722-725).—On account of the serious injury caused by the larch disease in areas where larch is grown as a pure crop, a number of methods have been suggested for reducing the liability to serious loss.

A method, known as the Novar system, suggested by Mr. Munro Ferguson, is described which reduces the liability to loss very considerably. This consists of planting pure larch woods, and when the trees attain an age of 16 to 20 years all are removed except the soundest, of which from 300 to 500 per acre are left. Stems that are sound or fairly sound at this age are not likely to suffer from disease later in life.

In order to keep the surface of the ground clear of grass and similar vegetation, additional trees are provided, and for this purpose it is suggested that Norway spruce, silver fir, or beech be planted underneath the fir, all these species being tolerant to shade. Other species have been experimented with and the list can probably be considerably extended. In about 20 years from the first thinning the larches will be thinned again so as to have a stand of 100 to 200 trees per acre, which will be ready for market at from 60 to 80 years.

Notes on the variation and possible parasitism of *Ganoderma sessile*, J. B. POLLOCK (*Rpt. Mich. Acad. Sci.*, 7 (1905), pp. 53, 54).—A brief account is given of the occurrence of specimens of this fungus, which were found on a maple tree in the University of Michigan campus, and in addition has been reported on oak trees from other localities.

The author notes some variations from the original description, and shows that it has stipitate as well as sessile forms. In considering the effect upon the host it is believed to be a wound parasite which destroys the bark and cambium of the tree but does not attack the living wood.

Bud rot of carnations, F. D. HEALD (*Abs. in Science, n. ser.*, 23 (1906), No. 590, p. 620).—A troublesome bud rot of carnations due to a species of *Fusarium* is described. The rotting buds always contained a mite in addition to the fungus.

Pure cultures were made of the fungus, and successful inoculations were carried out. The fungus was again isolated and new inoculations made which indicated that the fungus alone was capable of producing the rotting. The experiment with inoculations of the mite into the buds did not produce the disease. It was suggested that the mites act only as carriers of the fungus and intensify its severity. The Lawson carnation was noticed as the most susceptible variety.

A disease of narcissus, F. J. CHITTENDEN (*Gard. Chron.*, 3, ser., 39 (1906), No. 1010, p. 277, fig. 1).—The author reports the occurrence in a field of *Narcissus poeticus* of a disease which does not appear to have been noticed heretofore. Both leaves and flower stalks were affected, but the bulbs appeared not to suffer except in so far as they were injured by interference with the functions of the leaf.

The disease is characterized by the presence of yellowish-brown spots on the leaves and flower stalks, the spots sometimes appearing at the tips of the leaves, but usually some distance below. The disease usually makes its first appearance about the end of April, and where the cells are killed the upper part of the leaf stalk or flower stalk frequently bends over. When the flower stalk is attacked the flowers naturally suffer, sometimes failing to open entirely, and they are always injured for market purposes on account of the reduction in the length of the stalk.

The fungus, which appears to be hitherto undescribed, is a species of *Ramularia*, to which the name *R. narcissi* is given. A technical description is appended.

The best means of preventing the disease thus far known seems to be a solution of one-half ounce of potassium sulphid in a gallon of water.

A species of *Hormodendron* on *Araucaria*, J. B. POLLOCK (*Rpt. Mich. Acad. Sci.*, 7 (1905), pp. 56, 57).—The writer's attention was recently called to an olive-colored mold-like growth on the surface of living branches and leaves of an *Araucaria* grown as a house plant. The growth while not copious was easily visible by the fact that the parts coated by the fungus were of a noticeably different color from the normal parts. An examination showed that the fungus was a species of *Hormodendron*, probably *H. cladosporioides*. Later the same fungus was found in a greenhouse at Ann Arbor growing on diseased violet leaves.

The only species of *Hormodendron* that has been described as an active parasite is *H. hordei*, which is quite destructive to barley. The question is raised as to whether the fungus on the *Araucaria* is parasitic or not, and it is believed that the condition under which the plant was grown indicates that if parasitic the fungus is only weakly so.

Directions for making Bordeaux powder, R. M. BIRD (*Missouri Sta. Circ. Inform.* 20, pp. 3).—As the result of experience in the use of dry Bordeaux mixture powder in orchards, a modification of the directions for making the mixture previously given (*E. S. R.*, 15, p. 166) is noted, whereby the work is simplified and much of the annoyance of flying dust and lime is avoided.

As now recommended, 10 lbs. of copper sulphate is dissolved in 4 gal. of hot water. From a barrel of quicklime 5 lbs. of the best is taken to make a milk-of-lime solution with 4 gal. of water. The remaining lime is slacked to a perfectly dry dust. The copper and milk-of-lime solution are poured together simultaneously into a third vessel and stirred until no greenish streaks appear, after which the mixture, water and all, is scattered in the lime dust and mixed with a rake. While still somewhat damp it is rubbed through the sieve and spread out to dry. This requires a day or two, after which the mixture will keep indefinitely. These quantities make about 250 lbs. of powder.

Bordeaux mixture, G. GÁNDARA (*Com. Par. Agr. [Mexico], Circ.* 35, pp. 9, figs. 11).—Directions are given for the preparation and application of Bordeaux mixture for the control of various fungus diseases.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Directions for destroying pocket gophers, D. E. LANTZ (*U. S. Dept. Agr., Biol. Survey Circ.* 52, pp. 4, figs. 3).—Pocket gophers are distributed almost everywhere west of the Mississippi and are occasionally so injurious that they must be combated by means of strychnin, carbon bisulphid, or traps. The present circular is based on Bulletin 5 of the Biological Survey (*E. S. R.*, 7, p. 20).

Directions for preparing specimens of large mammals in the field, C. H. MERRIAM (*U. S. Dept. Agr., Biol. Survey Circ.* 49, pp. 4, figs. 6).—For the pur-

pose of assisting field agents and others in preparing satisfactory skins for shipment to the Bureau, directions are given regarding measuring, skinning, drying, and otherwise preserving the skins of mammals of all sizes. Suggestions are also made regarding labeling, packing, and shipping of such specimens.

Importation of snakes into Hawaii, J. WILSON (*U. S. Dept. Agr., Biol. Survey Circ. 48, p. 1*).—Notice is given that on and after August 1, 1905, no permits shall be issued for the introduction of snakes of any kind into any part of the Hawaiian Islands.

Directory of State officials and organizations concerned with the protection of birds and game, 1905, T. S. PALMER (*U. S. Dept. Agr., Biol. Survey Circ. 50, pp. 16*).—This directory, which has been published since 1900, has been revised in the present issue to August 15, 1905. In summarizing the contents of the circular it is shown that in 36 States the enforcement of the game laws is entrusted to State officers, in 6 States to county officers, and in Virginia to city or district wardens.

List of publications of the Biological Survey, Department of Agriculture (*U. S. Dept. Agr., Biol. Survey Circ. 51, pp. 6*).—A list is given of the bulletins, North American fauna, circulars, farmers' bulletins, and reprints of Yearbook articles furnished by the members of the Bureau.

The monthly bulletin of the division of zoology, H. A. SURFACE (*Penn. Dept. Agr., Mo. Bul. Div. Zool., 3 (1906), No. 10, pp. 303-332, pls. 4*).—The life history, food plants, distribution, and injurious attacks of the San José scale are outlined and notes are given on the inspection service and treatment undertaken for the purpose of suppressing this pest. A lime-sulphur-salt wash is used according to the formula 22-17-10-50, boiled by the aid of artificial heat. The author recommends boiling for 1 hour. Notes are also given on the self-boiled lime-sulphur-soda wash, whale-oil soap, oil emulsions, and other remedies.

Twentieth report of the State entomologist on injurious and other insects of the State of New York, 1904, E. P. FELT (*N. Y. State Mus. Bul. 97, pp. 359-597, pls. 19, figs. 24*).—During the year under report an unusually small amount of injury to agricultural crops was caused by insect pests.

An investigation was made of methods for combating the grape rootworm. It was found that this insect deposits 45 per cent of its eggs within the first 2 weeks of the period of egg laying and 73 per cent during the month of July. The most successful means of combating this insect was found in beetle catchers, which have proved very satisfactory throughout the extensive tests of the past 3 years. On an experimental area of 5 acres over 150,000 beetles were captured in this manner, the number of the pest being reduced about 98 per cent.

Further experiments were made with arsenical poisons, but the results obtained from this method are difficult of estimation on account of the great activity of the beetles. Apparently about 50 to 60 per cent of the beetles may be destroyed by keeping the grapevines covered with an arsenical solution. Some of the pupæ may be destroyed by a thorough cultivation. It is therefore recommended that a ridge of earth be thrown upon the base of the vines in the fall or early spring and removed during the first half of June.

A long series of tests was made with various forms of lime-sulphur wash in combating the San José scale. In preliminary laboratory experiments ordinary washing soda appeared to give much better success in obtaining a combination of lime and sulphur than when caustic soda was employed. Washing soda has the advantage over caustic soda that it may be purchased almost anywhere and requires no special care in handling. A great variety of formulas were tested in the preparation of lime-sulphur wash with or without caustic soda or washing soda.

In these experiments it was found that all of the lime-sulphur combinations were almost equally effective. It appears to be possible, therefore, to allow a relatively wide range in the proportions of the ingredients of this wash. In general, however, the author prefers a formula calling for 20 lbs. lime and 15 lbs. sulphur per 50 gal. water with a boiling period of at least 30 minutes. The 2 other formulas especially recommended contain the same amount of lime and sulphur and 4 to 6 lbs. caustic soda or 10 lbs. washing soda.

Brief notes are given on various insects which caused more or less damage during the year. These include fruit-tree bark-beetle, apple-leaf miners, tussock moth, fall webworm, violet sawfly, buffalo tree hopper, pea louse, larder beetle, etc. Another attempt to establish *Chilocorus similis* appeared to be unsuccessful. The voluntary entomological service of the State is briefly described and a list of publications by the entomologist is presented together with a catalogue of contributions to the collection of insects.

Considerable attention was given to mosquitoes. A table is presented for the identification of mosquito larvæ, several new species are described, and notes are given on their life history. Notes are also given on the life history, habits, and distribution of the gypsy moth and the brown-tail moth.

H. Osborn made a study of the Jassidæ of New York State, and presents a discussion of these insects based on a list of 175 species found in the State (pp. 498-545). A list of Lepidoptera taken at Keene Valley, New York, is presented by G. F. Comstock.

Report of the entomologist, J. FLETCHER (*Canada Expt. Farms Rpts. 1905, pp. 159-200, pl. 1*).—During the year under report the Hessian fly was not particularly injurious. Some observations were made on the insect parasites of this pest. In Manitoba and the Northwest Territories the western wheat-stem sawfly caused some injury, and complaints were also made regarding joint worm, wheat midge, and cutworms in cereals. The method of using poisoned bran in the control of these pests is very satisfactory. It is stated that the Criddle mixture still proves effective when used against locusts. Notes are also given on bee moth, rose chafer, stalk borer, bollworm, variegated cutworm, carrot rustfly, cucumber beetle, sugar-beet webworm, San José scale, codling moth, woolly aphis, apple maggot, strawberry weevil, *Otiorrhynchus ovatus*, larch sawfly, spruce gall louse, Tussock moth, *Therina somnularia*, etc.

A report of the work of the apiary for the season of 1905 was made by J. Fixter (pp. 194-200). Successful attempts were made to prevent swarming by offering more room for brood comb and honey production. Attention is called to the desirability of keeping a close watch on the annual production of each colony of bees in order to improve the productiveness of the whole apiary. It is believed that in this way the amount of honey production may be considerably increased. The use of queen cells in small nuclei is explained as a system of queen rearing. In the case of infestation of combs by the bee moth, these pests may be destroyed by a fumigation with sulphur.

On some injurious insects in 1905, R. S. MACDOUGALL (*Trans. Highland and Agr. Soc. Scot., 5, ser., 18 (1906), pp. 224-237, figs. 23*).—Notes are given on a number of insects injurious to garden crops and forest trees. These pests include *Centhorrhynchus salicollis*, *C. assimilis*, and *C. contractus* attacking cabbage and turnip, pea and bean weevils, carrot fly, turnip flea-beetle, grain weevil, diamond-back moth, crane flies, pine weevils, pine sawfly, goat moth, etc.

The remedy recommended for the cabbage and turnip weevils consists in soaking the seed for 4 hours in turpentine or kerosene. The carrot fly may be largely controlled by spraying with kerosene emulsion after sowing, again after germination, and a third time after thinning the carrots.

Some insects injurious to forests. The locust borer, A. D. HOPKINS (*U. S. Dept. Agr., Bur. Ent. Bul. 58, pt. 1, pp. 16, pl. 1, figs. 6*).—Attention is called to the unusually serious depredations by this insect upon the black locust. In some localities the damage has been so great as to be unprofitable to grow the tree for shade or timber. The author considers it inadvisable, however, to abandon all attempts to cultivate the locust on account of the presence of the borer.

Detailed notes are given on the habits and life history of this species and on its distribution. With regard to the control of the locust borer the author suggests that infested trees be cut between the first of May and middle of September and utilized in such a way as to destroy the immature forms of the insect in the bark and wood. It may be possible to find localities in which the borer is not particularly injurious. The insects may also be readily collected from the flowers of golden-rod. Experiments will be conducted to determine whether a resistant race of black locust trees can be propagated. A bibliography of the articles relating to this insect is also given.

The principal insects injurious to the cocoanut palm, C. S. BANKS (*Philippine Jour. Sci., 1 (1906), No. 2, pp. 143-167, pls. 11*).—*Oryctes rhinoceros* is most frequently found in heaps of decaying vegetation. The larvae attack the soft-growing point of the cocoanut. This pest is described in its various stages.

The injurious attack of the insect proceeds from above downward. The adult beetle makes burrows for egg laying and for securing food, and nearly all cocoanut trees in the Philippines are eaten somewhat by this pest. Direct remedies are very difficult to apply, but considerable benefit may be derived from cleaning away all weeds, underbrush, and other rubbish underneath the cocoanut trees. Notes are also given on the habits, life history, and injurious attacks of *Rhynchophorus ferrugineus* and other insects which attack the wood of the cocoanut.

The corn root louse, J. J. DAVIS (*Ill. Agr., 10 (1906), No. 7, pp. 213-218, figs. 6*).—The economic importance and distribution of this pest are briefly described and notes are given on the amount of damage which it may cause if left without any treatment. The pest is cared for by the common brown ant. Notes are given on the success which has recently been had by the Illinois Experiment Station in combating this pest by thorough cultivation of the soil before planting and late in the fall.

The cotton worm, R. S. WOGLUM (*N. C. Dept. Agr. Ent. Circ. 16, pp. 8*).—The habits, life history, and means of combating this pest are briefly described. As artificial remedies, dusting with Paris green mixed with flour or air-slaked lime, and spraying with Paris green and lime in water are recommended.

Experiments to control the pea worm, N. S. BLAIR (*Canada Expt. Farms Rpts. 1905, pp. 311, 312*).—Pea vines were sprayed with Paris green at the rate of $\frac{3}{4}$ lb. to 40 gal. of water to which a little whale-oil soap was added to make the mixture adhere more thoroughly. In some cases the amount of Paris green was doubled. It appears that the early varieties of peas are much less subject to injury from the pea worm than the later varieties. Spraying with Paris green just as the pods are beginning to form appears to be not so effective as when the operation is done a little later.

Combating the grain weevil, M. ALBRECHT (*Wehnschr. Tierheilk. u. Viehzucht, 49 (1905), No. 52, pp. 826, 827*).—On account of the great destruction which this insect causes to corn and other cereal grain, a number of remedies have been suggested for controlling it. According to the author, if dry sand be mixed with grain infested with the weevil, the insects will crawl out of the grain as soon as possible and will not penetrate back into the sand. They may therefore be easily destroyed on the surface of the sand.

On a crane fly (*Tipula parva*), S. ONUKI (*Bul. Imp. Cent. Agr. Expt. Sta. Japan, 1 (1905), No. 1, pp. 90-94, pl. 1*).—The larvae of a supposed crane fly temporarily referred by the author to *Tipula parva* is widely distributed in Japan and is one of the worst pests of rice in that country. In some localities from 60 to 90 per cent of the seedlings are destroyed. There are two annual generations of the insect. The pest is described in its various stages. It appears that the larvae can not exist in water for a long time and flooding for 6 to 36 hours is therefore the easiest, cheapest, and most effective method of controlling the insect.

Ravages of the gypsy and brown-tail moths (*Medford, Mass.: Medford Mercury, 1906, 2, ed., pp. 10, pls. 122*).—This volume contains a brief account of the present distribution of the gypsy and brown-tail moths, with notes on the injury caused by these pests and a copy of the act of the Massachusetts legislature, approved May 5, 1905, providing for the suppression of the gypsy and brown-tail moths. The major portion of the volume is occupied with a series of reproductions of photographs showing the prevalence of the gypsy and brown-tail moths in various parts of the infested district and the damage done by these pests to trees.

Spraying apples for the plum curculio, S. A. FORBES (*Illinois Sta. Bul. 108, pp. 268-286, figs. 4*).—The author first began his work on methods of controlling the plum curculio on apples in 1885.

Elaborate experiments were carried out in 1904, using arsenate of lead as an insecticide. Different sets of trees were sprayed from 6 to 8 times, at intervals of about 10 days, between May 6 and July 28. The apples obtained from sprayed and unsprayed trees were collected, counted, and notes made on their condition. It appeared that the yield of the orchard was increased by about one-half as the result of spraying, while the size of the fruit was increased about one-fifth, thus making the value of the apple crop 2 to 3 times as great as it would be without the spraying.

The cost of spraying was 17 cts. per tree for four applications; the work costing 15 cts. and material 2 cts. Since arsenate of lead adheres quite firmly to the skin of the apple a chemical analysis was made to determine whether apples sprayed with this insecticide would be injurious as food. According to this analysis one grain of arsenic was found adhering to four pounds of apple peelings, when the fruit was removed, one day after being sprayed with four times the usual strength of the insecticide.

The author also discusses the influence of sprayed and unsprayed blocks of trees upon one another, particularly with reference to the conclusions to be drawn from spraying experiments.

Spraying apples for the plum curculio, S. A. FORBES (*Illinois Sta. Bul. 108, abs., pp. 3*).—A brief summary of Bulletin 108, noted above.

Comparative experiments with various insecticides for the San José scale, S. A. FORBES (*Illinois Sta. Bul. 107, pp. 241-261*).—In control work in orchards infested with San José scale the author tested 11 insecticide mixtures, with particular reference to their effectiveness and cost.

The results obtained in these experiments indicate that mixtures of lime and sulphur, without any other ingredient, are cheapest and most efficient. In the experiments in question these mixtures cost from \$0.84 to \$1.03 per 100 gal., while the California wash, containing salt, cost from \$0.94 to \$1.07 per 100 gal.; Oregon wash about the same, and self-boiled mixtures of lime and sulphur cost considerably more. Some of the commercial insecticides, containing the same ingredients, cost as much as \$5 per 100 gal.

In general the early spring appeared to be the best time for treating trees for scale insects, while the midwinter treatments were far less effective. Proprie-

tary soluble oil mixtures are easily applied, but are somewhat less efficient than lime and sulphur and cost about $2\frac{1}{2}$ times as much. Whale-oil soap was also found to be efficient, but cost nearly 8 times as much as lime and sulphur.

Comparative experiments with various insecticides for the San José scale, S. A. FORBES (*Illinois Sta. Bul. 107, abs., pp. 3*).—A brief summary of bulletin 107, noted above.

The cottony maple scale, S. A. JOHNSON (*Colorado Sta. Bul. 116, pp. 16, figs. 4*).—Brief notes are given on the distribution, food plants, life history, natural enemies, and treatment for this pest.

Attention is called to the fact that the insect is ordinarily not as injurious in natural forests of maples as upon maple trees planted for shade purposes on lawns and along highways. Experiments were made with kerosene emulsion, varying in strength from 5 to 50 per cent, with whale-oil soap, and with a proprietary insecticide. It appears from these tests that the cottony maple scale may be controlled by application in winter of kerosene emulsion at a strength of 15 per cent or greater, or by the use of whale-oil soap at the rate of 1 lb. to 1 gal. of water. Under unfavorable conditions it may be necessary to use a slightly greater strength of the insecticides.

The winged form of phylloxera, H. FAES (*Chron. Agr. Vaud, 18 (1905), No. 23, pp. 580, 581*).—Experiments were undertaken to determine the conditions under which the winged form of this insect appears. When underground forms were collected in warm weather and kept under close observation, winged forms appeared within 5 days. In cold weather the winged forms did not appear at all.

The farmer's garden and its enemies, W. W. FROGGATT (*Agr. Gaz. N. S. Wales, 16 (1905), No. 10, pp. 1034-1040, pl. 1, figs. 6*).—According to the author too little attention is paid to the insect pests of garden crops. Notes are given on the appearance, habits, and means of combating snails, slugs, centipedes, bollworm, cabbage aphid, potato moth, diamond-back cabbage moth, *Plusia verticillata*, *Nysius vinitor*, *Aulacophora hilaris*, etc.

Fifty years' progress in the practical control of insect and fungus pests of Illinois horticulture, S. A. FORBES (*Trans. Ill. Hort. Soc., n. ser., 39 (1905), pp. 219-227*).—Brief historical notes are given on the work of investigators regarding insect and fungus pests in Illinois with special reference to the developments which have been accomplished in insecticides and fungicides.

The control of insects, fungi, and other pests, G. M. BENTLEY (*Tennessee Sta. Bul., Vol. XVIII, No. 4, pp. 31-45, figs. 4*).—Suggestions are made regarding the preparation of the standard insecticides and fungicides and their application in the control of the more important insect pests and fungus diseases.

Insects and insecticides, C. P. GILLETTE (*Colorado Sta. Bul. 114, pp. 46, figs. 33*).—This bulletin is essentially a revision of Bulletin 71 of the station, with additional notes on the insect pests of currants and gooseberries (E. S. R., 14, p. 169).

The fumigation of nursery stock, A. F. BURGESS (*Ohio Dept. Agr., Div. Nursery and Orchard Insp. Bul. 6, pp. 18, pls. 7*).—During the fall of 1904 a series of experiments was made to test the effect of fumigation upon nursery stock. For this purpose peach, plum, apple, pear, cherry, and privet trees were used. The time of exposure varied from 40 minutes to 5 hours and the amount of cyanid from $\frac{1}{2}$ to 3 oz. per 100 cu. ft.

From these experiments it appears that fumigation is the best known method for treating nursery stock. It destroys all living insects with the exception of the larvae of borers. It is less effective on the eggs of oyster-shell bark-louse or scurfy scale. Nursery trees and shrubs may be injured if treated with excessive strengths of gas, but no injury was caused by the use of 1 oz. of cyanid per 100 cu. ft. for an exposure of 40 minutes.

In general it is believed that nursery stock is more injured by the treatment before and after fumigation than by the process of fumigation. In order to obtain successful results it is necessary that the fumigating house be gas tight and that the chemicals be of high grade. Fumigation of orchard trees in Ohio is considered impracticable.

Spraying fruit trees, A. DICKENS and R. E. EASTMAN (*Industrialist*, 32 (1906), No. 28, pp. 435-444, figs. 4).—During recent years it is said that the quality of fruit produced in Kansas has somewhat deteriorated on account of lack of attention to the necessity of spraying. The general importance of spraying is briefly referred to and notes are given on methods of controlling codling moth and other insects, together with an account of some of the most effective insecticides, such as arsenate of lead and a combination of Bordeaux mixture and Paris green.

Petroleum emulsions, C. L. PENNY (*Delaware Sta. Bul.* 75, pp. 39).—On account of the importance of soluble oils in spraying for various scale insects, the author made a study of various methods by which such combinations can be brought about.

It appears that a potash soap can be dissolved in kerosene more readily than a soda soap. Soaps are most efficient as emulsifiers when they are made from neatsfoot or sweet oil, while those made from cotton-seed oil, lard or castor oil are poorly adapted to the purpose. Commercial oleic acid and fish oil seem to be particularly excellent emulsifiers. Various combinations may be used in producing soluble oils. It is not necessary to use soap alone, but carbolic acid, ammonia, alcohol, or even water may assist. If soap with or without other materials is capable of emulsifying 25 times its weight of kerosene oil the ratio is said to be a high one. The author found it possible to prepare an emulsifier which would produce a satisfactory emulsion when mixed with 40 to 100 times its weight of kerosene.

It is found that if emulsions are made without any free oil they may then be diluted with water indefinitely without danger of separation into component parts. In general it is desirable to obtain a mixture with a high ratio or one in which the amount of oil is very large as compared with the soap. It appears that if a little water is added to the soap before mixing with the full amount of kerosene the emulsion is made much more easily.

After preparing soluble oils by means of an emulsifier and kerosene or petroleum it may seem desirable in some cases to add some other insecticide to the mixture. Most of these substances, however, are incompatible with soluble oils and cause them to decompose. Paris green is about the only exception.

A number of detailed formulas are given for the preparation of the petroleum emulsions. The various formulas are given for the purpose of showing how emulsions can be made but without recommendations of their efficiency in destroying insects since they have not been thoroughly tested by the station.

Chemistry of insecticides and fungicides, F. T. SHUTT (*Canada Expt. Farms Rpts.* 1905, pp. 149-154).—The soda-Bordeaux or Burgundy mixture was prepared according to 2 formulas calling for 4 to 6 lbs. of copper sulphate and 5 to 7½ lbs. of carbonate of soda per 40 gal. of water.

This mixture has been used chiefly for potatoes. It was tested on orchard trees with the result that it proved harmless to the foliage except when Paris green was used in connection with it. Brief mention is also made of the use of limoid in the preparation of kerosene emulsion and of flour also used for this purpose. It is found possible to make a valuable emulsion with kerosene by adding flour at the rate of 8 oz. to 1 qt. and water added at the rate of 2 gal. for every quart of kerosene. After thorough churning the mixture is then ready for use. The flour emulsion spreads readily and does not clog the nozzle.

Notes are also given on formalin and milky formaldehyde as a smut preventive and potassium cyanid for fumigation purposes.

A chemical study of the lime and sulphur dip, R. H. SHAW (*Trans. Kans. Acad. Sci.*, 20 (1905), pt. 1, pp. 53-60).—Some time has been spent by the author in investigating the chemical composition of lime and sulphur dips.

In order to study the composition of this dip and the changes which it undergoes, small vats were constructed in the laboratory so as to provide conditions as nearly as possible like those which prevail in actual field work. During the first day the ratio of calcium in thiosulphate to the calcium in the sulphids was as 1:8, while on the sixteenth day it was 5:8. Likewise on the first day the ratio of the sulphur in the thiosulphate to the sulphur in the sulphids was as 1:13, while on the sixteenth day it was 4:13. The specific gravity was also found to increase constantly and regularly. This is due to concentration from the evaporation of water and also to the oxidation of sulphids.

On certain tropical ants introduced into the United States, W. M. WHEELER (*Ent. News*, 17 (1906), No. 1, pp. 23-26).—*Monomorium destructor* was reported from Florida and Alabama. This ant is believed to have been recently introduced from the Tropics. It feeds on either vegetable or animal substances. Two other tropical ants have recently appeared in the United States, *Iridomyrmex humilis* and *Prenolepis longicornis*.

The deposition of eggs and the larval life of Tabanidæ, A. LÉCAILLON (*Ann. Soc. Ent. France*, 74 (1905), No. 1-2, pp. 20-28, pl. 1, fig. 1).—A brief review is given of the literature relating to this subject.

The author's observations were confined largely to *Tabanus quadrimotatus*. The female of this species lays its eggs on the stems of various plants at a short distance above the ground. The eggs are deposited in large masses attached to these plants and the female appears to select sometimes a moist and sometimes a comparatively dry locality for oviposition. The larvæ hatch within 13 days or occasionally a longer period and live in the soil, feeding on animal or vegetable material.

According to the author's observations the larvæ did not attack other insect larvæ placed conveniently for them, but would suck out the juices of such insects after they had been killed.

The eradication of warble flies by the cooperation of dairy associations, N. VILLEMOS (*Ztschr. Fleisch u. Milchhyg.*, 16 (1906), No. 7, pp. 226-228).—The first attempts along this line were without much result for the reason that sufficient interest was not felt in the matter by the individual dairyman. In subsequent years, however, the work of eradicating warble flies was prosecuted more industriously and with better success. In 1905 a total of 4,333 cows were treated at a cost of 58½ days' work, and the number of warble-fly larvæ destroyed was 10,396. The results shown in the greater comfort of the cows and larger yield of milk indicate that the treatment of dairy cows for warble flies is well worth while.

Internal morphology of the American cattle tick, W. E. ALLEN (*Studies Zool. Lab. Univ. Nebr.*, No. 67, pp. 245-280, pls. 4).—On account of the thorough manner in which the external anatomy of the cattle tick has been studied and described, the author confines his attention in the present article to the discussion of the internal morphology alone. The methods of preserving ticks for microscopic study are described and notes are given on the anatomy of all of the internal organs. A brief bibliography relating to the subject is appended to the paper.

The Ixodidæ of the Argentine Republic, F. LAHILLE (*An. Min. Agr. Argentina Secc. Zootec., Bact., Vet., y Zool.*, 2 (1905), No. 2, pp. 166, pls. 13, figs. 23).—This constitutes an elaborate monograph of the Ixodidæ found in Argen-

tina. The ticks belonging to this family and also the genus *Argas* are described with notes on their habits, life history, and economic importance.

The blood parasite which causes Texas fever and is carried by cattle ticks is discussed with particular reference to its proper name. The author believes that this should be *Babesia boris*. Analytical tables are presented for the identification of various species of the Ixodidae. A tabular list is also given showing the name of the tick, the name of the discoverer, the host, and locality. The genus *Boophilus* is retained and the common cattle tick is referred to under the name *B. annulatus*. The form found in Argentina may be a variety of the typical species.

From the literature of the subject and also from experiments carried out by the author data are presented regarding the reaction of ticks toward light, tobacco fumes, sarnol, and other substances. The subject of insecticides and dips for the destruction of ticks is presented with particular reference to American experiments in this field. It is held that ticks may be exterminated by a suitable system of pasture rotation.

Experiments with bees, S. A. BEDFORD (*Canada Expt. Farms Rpts.* 1905, pp. 345, 346).—Last year the bees were not placed in their winter quarters until November 28. A corner of a cellar under a residence is used for this purpose, being partitioned off, kept dark, and the temperature regulated as uniformly as possible. The amount of honey consumed during the year was 6 to 28 lbs. per colony with an average of 14 lbs. A test of the importance of ventilation in wintering bees indicated that it is not necessary to have a current of air passing through the hives provided the cellar is kept well ventilated.

A bee scale, C. DÉCHÉ (*Apiculteur*, 50 (1906), No. 4, pp. 143, 144, fig. 1).—A description is given of a simple scale weighing only 30 lbs. and capable of easy transportation from place to place. The scale is especially adapted for weighing colonies of bees, but may also be used for other purposes.

Beehives and bee keepers' appliances, P. N. HASLUCK (*London: Cassell & Co., Ltd.*, 1905, pp. 160, figs. 155).—The present volume contains a digest of information relating to beehives and other appliances necessary in bee raising. The material of the volume is arranged in chapters on bar-frame hives, temporary hives, tiering bar-frame hives, stocking beehives, permanent and temporary observatory hives, inspection case for hives, queen-rearing hive, bee smokers, honey and wax extractors, and miscellaneous appliances for bee keepers. The various devices described in the volume are well illustrated.

FOODS—HUMAN NUTRITION.

Some forms of food adulteration and simple methods for their detection, W. D. BIGELOW and B. J. HOWARD (*U. S. Dept. Agr., Bur. Chem. Bul.* 100, pp. 59).—The common forms of adulteration met with in baking powders, alcoholic and nonalcoholic beverages, canned vegetables, cocoa, chocolate, coffee, tea, condimental sauces, dairy products, flavoring extracts, fruit products, meat preparations, and other food products are described and discussed, and data summarized in tabular form showing the extent of adulteration as determined by American investigators.

Sugar, flour, and cereal breakfast foods, it is stated, are practically free from adulteration. "The rumors which have been circulated from time to time that arsenic and other poisonous substances are used in breakfast foods have been entirely without foundation. . . .

"There is an impression in some quarters, unfortunately, that flour is adulterated with ground gypsum or other mineral matter. It is also believed by many that alum is used for the purpose of whitening bread. It may be said, however, that these forms of adulteration are not practiced in this

country. . . . At the present time there is probably no product on our market more free from adulteration than wheat flour.

"Some adulteration is practiced in special kinds of flour. For instance, much of the so-called gluten flour on the market is not at all what it purports to be. Frequently untreated wheat flour is sold for gluten flour. Buckwheat flour and other special articles of that nature are also frequently adulterated with cheaper cereal products.

"As a class the sugars, both high and low grades, as found on the market are practically free from adulteration. During recent years, however, a product has been put on the market to a limited extent which consists of a mixture of cane sugar with starch sugar (glucose) and saccharin, the latter being an artificial sweetening material derived from coal tar. There is a popular belief that granulated sugar is often adulterated with white sand or pulverized rock, and that pulverized sugar is commonly adulterated with starch or lime dust. Cases of such adulteration, however, have never been found by this Bureau, and it may safely be said that they occur rarely if at all."

Simple methods are described for detecting the forms of food adulteration and sophistication which are most likely to occur.

Cotton-seed meal for bread, J. H. CONNELL (*Texas Farm and Ranch*, 25 (1906), Nos. 20, pp. 12, 13; 21, p. 12).—The author believes that cotton-seed meal may be used to advantage as a constituent of bread and other articles of food, and in connection with a lecture on the subject exhibited samples of foods made in part of cotton-seed meal.

On the protein substances of barley, in the grain itself and during the brewing processes, H. SCHJERNING (*Compt. Rend. Lab. Carlsberg*, 6 (1906), No. 4, pp. 229-307, pls. 2, *dyms.* 3).—From an extended study of the composition and changes in nitrogenous materials in barley during growth, ripening, and storage some general conclusions were drawn from which the following are quoted:

"An appreciable amount of proteose in a barley crop must always be considered as indicative of rather unfavorable harvest conditions.

"A loss of dry matter (respiration loss) is not likely to take place during the storage of barley, provided the storage takes place under suitable conditions, and providing also the barley sample has reached a suitable degree of maturity before being reaped.

"If reaped at an early stage, barley is less rich in nitrogen than it is if reaped later.

"The chemical composition of dry matter in respect of the various groups of nitrogenous substances, mineral constituents, and water-soluble acid combinations is, properly speaking, not dependent on the species, variety, or type of barley.

"The cultural condition of the soil, as also climatic conditions, exert some influence on the amount of mineral constituents in barley dry matter, and to a certain extent also upon the amounts of total nitrogen and amin-amid nitrogen, whereas with regard to the other groups of nitrogenous substances, the influence of these factors is less marked than the degree of maturity and time of storage."

Preparation of vegetables for the table, MARIA PARLOA (*U. S. Dept. Agr., Farmers' Bul.* 256, pp. 48).—Data are summarized regarding the structure and composition of vegetables, their classification, the principles which underlie vegetable cookery, wastes in preparing and cooking vegetables, the changes induced by cooking, and similar questions, and a number of typical recipes for cooking vegetables are given. In considerable part the data are based on the author's studies and experiments on the theory and practice of vegetable cookery.

The food of natives, A. LOIR (*Rev. Sci. [Paris]*, 5. ser., 5 (1906), No. 19, pp. 590-592).—The author reports observations on the diet of native laborers in South Africa, with special reference to the effect of diet on health. He considers that the monotonous diet, different in character from the food to which they were accustomed, was responsible for the illness observed. The article contains information on native foods and food habits.

Statement of information collected by the board of education and the foreign office regarding methods adopted in great continental and American cities for dealing with underfed children, R. L. MORANT (*London: Bd. Ed.*, 1906, pp. VI + 33).—Data collected in a number of continental and American cities regarding supplying food to school children are classified and arranged.

A comparative study of various fruit and vegetable colors, C. H. LA WALL (*Amer. Jour. Pharm.*, 77 (1905), No. 7, pp. 301-311).—The action of reducing reagents on the natural colors of a number of common fruits and other vegetable colors and anilin dyes was studied.

Except litmus and cudbear none of the vegetable colors was affected by the stannous chlorid reagent, though many were either rendered lighter or decolorized by zinc and hydrochloric acid. Most of the anilin colors were discharged by both reagents. Stannous chlorid reagent and zinc and hydrochloric acid, therefore, are regarded as useful reagents for studying the nature of the color of fruit preparations.

Concerning the storage of oxygen, H. WINTERSTEIN (*Zentbl. Physiol.*, 20 (1906), No. 2, pp. 41-44).—From experimental evidence the conclusion was reached that oxygen is not stored up in the nerve centers.

Physiological economy in nutrition (*Nature [London]*, 73 (1906), No. 1892, pp. 328-330).—A critical discussion of recently published work by R. H. Chittenden (*E. S. R.*, 16, p. 685) and O. Folin (*E. S. R.*, 17, p. 167).

ANIMAL PRODUCTION.

Studies in the chemical dynamics of animal nutrition, S. B. SCHRYVER (*Bio-Chem. Jour.*, 1 (1906), No. 3, pp. 123-166, figs. 2).—The various theories regarding the functions of nitrogenous constituents of food stuffs are discussed with reference to the general economy of nutrition and investigations summarized which bear upon this topic.

As a contribution to this subject the author has studied the character of the residual nitrogen in the serum and tissues, and autolysis and the relation of autolysis to nutrition. The general conclusion reached as to the functions of nitrogenous food stuffs in nutrition is that "in order to maintain nitrogenous equilibrium, nitrogenous food stuffs must be ingested in such quantities and in such form that the ammonia produced therefrom in the digestive tract is sufficient to maintain the intracellular alkalinity of the liver and probably other tissues.

"In order to fully understand this mechanism it is of importance here to consider the products other than nitrogenous bodies which are formed during autolysis. Magnus-Levy has shown that the liver on autolysis under the most stringent precautions for asepsis yields carbonic and other organic acids, such as lactic acid; furthermore, the degradation products of fats and carbohydrates are of acidic nature—all would on hydrolysis or oxidation produce acids; it matters not, however, for the purposes of the present argument whether the acid products are produced from the stored-up food stuffs or from the bioplasm itself.

"We have, therefore, two classes of products producible, viz. nonnitrogenous acidic bodies and nitrogenous bodies; the production of the latter class, it has

been shown, is stimulated by the presence of the former. In well-nourished animals there is, however, always an excess of ammonia present, hence in this case the tissues will not become acid *in vivo*. The excess disappears gradually, however, if the animal is deprived of food. A certain stage will then be reached, when the production of acid exceeds the amount of ammonia available for neutralization; the autolytic enzym then comes into play, liberates amino acids, etc., which in their turn pass the alimentary tract, and by means of the metabolic processes there taking place liberate ammonia, which again inhibits the production of nitrogenous degradation products. Degradation of tissue should proceed, therefore, at a definite uniform rate. From the preliminary experiments carried out it seems that the production of acids is inhibited by the presence of acids; we have, therefore, a mechanism which tends to prevent excessive acidity or alkalinity of the liver; in the presence of acid nitrogenous degradation products are formed, from which ammonia is produced in the digestive tract; it is possible also that the presence of alkali stimulates the production of the nonnitrogenous acid bodies. Further research is needed on this point.

"The production of nitrogenous degradation products proceeds also at such a rate that there is never a dearth of nitrogenous bodies in the blood stream, and the bioplasm of the tissues, especially the mucous membrane of the small intestine, can remain saturated with side chains, for we have seen that the liver of a fasting animal contains more residual nitrogen than does that of a well-fed animal.

"From these researches it follows that, while the animal derives most of its energy from the oxidation of carbohydrates and rapidly eliminates nitrogen from albumens, the latter, for all that, play an important rôle in nutrition, for the degradation products are needed, not only to satisfy, as Folin has suggested, the needs of endogenous metabolism of the organism representing the wear and tear of the tissues, but also to supply sufficient ammonia to maintain a certain amount of general intracellular alkalinity. In the absence of this amount, nitrogenous equilibrium ceases to be maintained."

Cattle feed and stock food, T. MACFARLANE (*Lab. Inland Rev. Dept. [Canada] Bul. 116, pp. 31*).—In the different Canadian inland-revenue districts 127 samples of feeding stuffs were collected and examined, including oil meals, coconut cake, gluten meal, calf meals, shorts, middlings, low-grade flour, bran chops, moulée, mixed feeds, corn meal, corn chop, cracked corn, corn feeds, barley meal, barley chop, chopped feeds, and provenders.

Forty samples of condimental feeds and similar goods were also examined. They were found to be largely artificial mixtures of grain products, oil-cake meal, organic substances, and inorganic salts. "In most of them the total ash is high, and in many of them the ash soluble in water is very high and consists almost entirely of common salt. It is certainly not necessary that as much as 20 per cent of it should be required for the preservation of a sound and wholesome food, and its addition seems to partake of the nature of a fraud. Occasionally sulphate of soda is present, perhaps to save time by administering a laxative simultaneously with the food, a practice which a veterinarian might possibly condemn. . . . Sometimes the total proteids are quite high, which is no doubt owing to an admixture of oil-cake meal. On the other hand, so far as nutritive value is concerned, many of these stock foods appear to be no better than bran or 'chop.' It is possibly on account of the added salt that these are dignified by the name of 'stock food.'"

Fodders and feeding stuffs, F. T. SHUTT (*Canada Expt. Farms Rpts. 1905, pp. 149-144*).—Analyses are reported of a number of samples of mixed feeds,

gluten meal and other corn by-products, linseed cake and meal, cotton-seed meal, distillers' grains, goose wheat, fall wheat, broken soda biscuit or crackers, rice meal, and condimental feeds.

Mealies grown at Potchefstroom (*Transvaal Agr. Jour.*, 4 (1906), No. 14, pp. 359-361).—Analyses of 10 samples of corn are reported. On an average the samples were drier than American-grown corn, doubtless owing to the dry South African climate. They contained "less protein and fat, but more starch, while they are about the same so far as ash and crude fiber are concerned."

"It would appear from these analyses that flint varieties of mealies, so far as chemical composition goes, are decidedly preferable for feeding purposes to dent varieties, and that the soft corn is poorest in ash, protein ('flesh formers'), and fat, though richest in starch."

Castor bean by-products, A. HALENKE and M. KLING (*Landw. Vers. Stat.*, 64 (1906), No. 1, pp. 51-86, figs. 13).—Available data regarding the histology of castor-bean seed, the composition of seeds and by-products, castor-bean products as adulterants, and other questions are summarized.

Blood molasses as a feeding stuff, G. MONTINI (*Staz. Sper. Agr. Ital.*, 38 (1905), No. 9, pp. 785-798).—Tests with farm animals are briefly summarized, showing the value of blood molasses as a feeding stuff.

Calculating rations, A. STUTZER (*Berechnung der Futterrationen*, Berlin: Paul Parey, 1906, 2. ed., pp. 81).—This is the second, revised, and enlarged edition of this popular treatise, which discusses the food requirements of different farm animals, the composition of feeding stuffs, method of calculating rations, and related questions.

Concerning the composition of animal fat, C. SCHNEIDER and S. BLUMENFELD (*Chem. Ztg.*, 30 (1906), No. 6, pp. 53, 54).—The chemical and physical constants of fat from seal, lynx, bear, crane, and other sorts of game are reported.

Live stock, J. H. GRISDALE (*Canada Expt. Farms Rpts.*, 1905, pp. 47-51, 73-75).—It is estimated that the average cost of feeding and care of work horses at the station is 32.33 cts. per working day.

The extensive use of bran in the place of oats has effected a very considerable saving in the cost of horse feeding during the year, and the value of bran and oats in different proportions as compared with oats alone was studied with 5 lots containing 2 work horses each, the grain ration being supplemented with mixed hay. On some of the rations there were small gains and on others losses, but in general the conclusion was reached that bran may "very safely and very profitably constitute a very large percentage of the meal ration of working horses. Probably equal parts bran and oats might be taken as a fair proportion in which to mix the two feeds. Where the mixture is being fed to horses with sound teeth there does not seem to be any particular advantage in grinding the oats."

Beef production, J. H. GRISDALE (*Canada Expt. Farms Rpts.*, 1905, pp. 62-70).—In short *v.* long feeding periods a lot of 9 steers was fed for 127 days in comparison with a similar lot fed 202 days. The average daily gains per steer in the 2 cases were 1.85 and 1.83 lbs., and the cost of a pound of gain 6.76 and 7.38 cts., respectively.

The influence of age on the cost of beef was studied, the average daily gain with 3-year-olds being 1.65 lbs. per head at a cost of 6.52 cts., with 2-year-olds 2.16 lbs. and 5.99 cts., with yearlings 2 lbs. and 4.3 cts., and with skim-milk calves under 8 months 1.54 lbs. and 3.4 cts.

Continuing earlier work (E. S. R., 17, p. 171), the cost of producing baby beef was studied with steers 2 years old, with steers 13½ months old, and with calves, full fattening rations and limited growing rations being compared in

each case. With 2-year-olds the greatest gain, 1.66 lbs. per head, was noted with a lot of 5 animals on a full fattening ration, the test covering 110 days, and the smallest gain, 1.19 lbs. per head, in the case of a similar lot fed a limited growing ration for 786 days. The greatest range in cost of gain was also noted with these lots, the values being 7.28 and 4.37 cts.

With the yearling steers the greatest gain, 2 lbs. per head per day, was noted on the full fattening ration, the experimental period covering 193 days, and the smallest gain, 1.47 lbs. per head per day, with a lot fed the limited growing ration for 169 days. With calves the daily gain on a limited growing ration was 1.3 lbs. per head in a test covering 201 days, and on a full fattening ration 1.54 lbs., the cost of a pound of gain in the 2 cases being 3.58 and 3.4 cts., respectively.

Cattle, R. ROBERTSON, S. A. BEDFORD, and A. MACKAY (*Canada Expt. Farms Rpts. 1905*, pp. 287, 288-297, 341-343, 394-396).—The herds kept at the Maritime Provinces, Manitoba, and Indian Head experimental farms are described and feeding tests reported.

At the Maritime Provinces farm, 8 steers fed loose in stalls gained 2,900 lbs. in 165 days as compared with 2,010 lbs. gained by a like number tied in stalls. Considering all the steers the average daily gain was 1.55 lbs. per head and the cost of a pound of gain 9.33 cts.

The influence of age on the cost of beef production was tested with 3-year-olds, 2-year-olds, and yearlings, 8 animals constituting a lot in each case. The 3-year-olds gained at the rate of 1.64 lbs. per head per day, the cost of a pound of gain being 8.76 cts. Similar values with the 2-year-olds were 1.70 lbs. and 8.44 cts., and with the yearlings 1.75 lbs. and 7.06 cts.

Continuing earlier work (E. S. R., 17, p. 171), full fattening and limited growing rations were compared. Summarizing the data it was found that steers fed a full fattening ration for an average of 637 days made an average daily gain of 1.49 lbs. per head, the cost of a pound of gain being 5.78 cts. Animals fed a limited growing ration for 1,108 days on an average gained 1.08 lbs. per head per day at a cost of 6.1 cts.

At the Manitoba experimental farm in a test covering 112 days, the average daily gain made by a lot of 6 yearlings was 1 lb. 11 oz. per head per day and by 6 2-year-olds 1 lb. 7 oz. under similar conditions of feeding, the calculated profit in the 2 cases being \$2.22 and \$2.51. The results were practically the same as those obtained in an earlier test (E. S. R., 17, p. 172). "There is very little profit in fattening steers when the difference between the buying price in the fall and the selling price in the spring is not more than \$1 per 100 lbs."

At the Indian Head experimental farm the average gain of 4 2-year-old steers was 240 lbs. per head in a test covering 16 weeks and the calculated profit per steer \$5.07. Similar values for a lot of 4 3-year-old steers fed a similar ration were 219 lbs. and \$4.17.

Swine feeding, J. H. GRISDALE (*Canada Expt. Farms Rpts. 1905*, pp. 70-73).—Alfalfa, clover, and root pasture supplementing meal rations were compared with roots and meal fed in pens and with meal fed in pens without supplementary feed, using 5 lots of 5 pigs each.

In the 35 days of the test the gain ranged from 1.31 lbs. per head per day on root pasture to 1.77 lbs. with the lot fed roots inside. The gain was most cheaply made with the last-mentioned lot, costing 3.09 cts. per pound, and was most costly, 4.23 cts. per pound, with the lot fed meal without supplementary feed in pens.

When pigs were pastured on an acre of ripe peas "the returns in pork were not satisfactory, but the effect of the exercise and the peas together was wonderfully beneficial so far as form of pigs was concerned and so far as fitting them for finishing off for the packer when brought into the pens."

Swine, R. ROBERTSON, S. A. BEDFORD, and A. MACKAY (*Canada Expt. Farms Rpts. 1905, pp. 297, 298, 343, 344, 396, 397*).—Brief statements are made regarding the pigs kept at the Maritime Provinces, Manitoba, and Indian Head experimental farms.

At the Maritime Provinces farm 10 pigs pastured on clover, rape, and hairy vetch and fed milk and meal 1:1 made an average daily gain of 0.74 lb. from July 1 to October 1. A similar lot fed on milk and meal only made an average daily gain of 0.90 lb. per head. Both lots were then fed under like conditions until November 15, the average daily gains being 1.3 lbs. and 0.95 lb. per head, respectively.

At the Manitoba experimental farm 12 pigs pastured on brome grass and fed grain in addition gained 995 lbs., the calculated profit being \$33.38.

First annual report of the Poultry Institute of the Province of Ontario, G. C. CREELMAN (*Ann. Rpt. Poultry Inst. Ontario, 1 (1905), pp. 87*).—A brief account of the meeting and a number of papers by different authors on various problems connected with poultry feeding. In one of these, entitled "Dry Feeding: The New Poultry Culture," by A. F. Hunter, the experience of a number of practical feeders on the value of dry rations for poultry is summarized.

Report of the poultry manager, A. G. GILBERT (*Canada Expt. Farms Rpts. 1905, pp. 233-261, pl. 1*).—Recent changes in the local poultry market are discussed, as well as other general questions of poultry feeding, and the results of tests on a variety of topics reported.

A progress report is made of tests undertaken with a view to building up prolific and satisfactory strains of poultry. Trap nests were used to insure accuracy in the individual egg records kept.

When hens 2 or 3 years old were compared with pullets the older birds produced the greater number of eggs. "To secure early winter layers in either cold or partly warmed houses the pullets should be hatched early and come from strong and vigorous parent stock. To have prolific layers of large eggs in either unheated or partly warmed houses the pullets should come from hens which have proved to be good layers of large eggs." The rations fed to these lots and the method of feeding are described in detail.

In the incubator tests it was found that eggs from hens kept in cold houses showed the greatest percentage of fertility and hatched the most chickens, facts which were brought out in earlier tests (*E. S. R., 17, p. 175*). The eggs with the weaker germs were laid by hens kept in partially warmed houses. The same rations were fed in both cases. "Eggs were turned once per day after cooling. During the cooling of the eggs the doors of the incubators were left open. Neither incubator required any moisture."

Eggs from hens which had laid well during the season and had a free run "showed remarkable fertility and strength of germ." Records were kept to ascertain how soon after mating eggs would hatch vigorous chickens. The shortest time recorded was 41 hours 50 minutes.

Poultry, R. ROBERTSON, S. A. BEDFORD, and A. MACKAY (*Canada Expt. Farms Rpts. 1905, pp. 298, 299, 344, 345, 397*).—The poultry kept at the Maritime Provinces, Manitoba, and Indian Head experimental farms are briefly spoken of.

At the Manitoba experimental farm 4 Plymouth Rock cockerels fed ground grain gained 4 lbs. in 21 days, the cost of feed being 24 cts., as compared with 3 lbs. gained by a similar lot fed the same grain ration (wheat and oats 3:1) unground, the cost of the feed in this case being 21 cts.

At the Indian Head experimental farm the records kept showed that Light Brahmas averaged 47 eggs each from April to October as compared with 56 eggs laid by Black Minorcas and 78 eggs laid by Plymouth Rocks.

DAIRY FARMING—DAIRYING.

Further investigations on the influence of individual food constituents upon milk production, A. MORGEN, C. BEGER, and G. FINGERLING (*Landw. Vers. Stat.*, 64 (1906), No. 2-3, pp. 93-242).—The investigations previously noted (E. S. R., 16, p. 696; 17, p. 286) were continued in a somewhat modified form during 1905. Eight sheep and 2 goats were made use of in the 3 series of experiments conducted.

The addition of fat to a ration poor in fat and protein increased to a marked extent the yield of milk and milk constituents and also the percentages of fat and total solids. The addition of protein to the same basal ration increased to a still greater extent the yield of milk and milk constituents, with the exception of the fat, which showed a decided diminution. The percentage of total solids was also reduced. The simultaneous addition of both fat and protein increased the yield of milk and fat and compensated for the unfavorable influence of the protein when added alone. The refractometer number of the milk fat was increased by the addition of fat to the ration, but was not affected by the addition of protein.

When the protein in a ration rich in protein and poor in fat was replaced to a greater or less extent by thermically equivalent quantities of fat, practically the same results were obtained. The yields of milk, total solids, sugar, and proteids were reduced and the yield of fat was increased both in percentage and absolute amount. The most favorable influence of the fat was exerted when the average amount fed was 1 gm. per kilogram live weight. The refractometer number of the milk fat increased approximately in proportion to the substitution of the fat for protein in the ration.

The substitution of a thermically equivalent quantity of fat for a part of the carbohydrates in the ration rich in protein and poor in fat increased the yield of milk and milk constituents, especially the fat.

These results, confirming those of the previous investigations, indicate that food fat is better suited for the production of milk fat than protein and carbohydrates and is the only food constituent which exerts a specific influence in this direction, as is shown not only by the yield of fat but by the changes in the properties of the fat. Protein and carbohydrates exert no such specific influence.

The influence of emulsified and nonemulsified fats of different kinds upon milk production, C. BEGER (*Landw. Vers. Stat.*, 64 (1906), No. 2-3, pp. 249-252).—This is a preliminary report on experiments with 1 sheep and 1 goat in which the influence upon milk production of feeding butter fat, peanut oil, palm-nut oil, and fat extracted from hay was studied. Of the 4 fats, butter fat exerted the greatest stimulating influence and hay fat the least. The palm-nut oil produced a marked lowering of the refractometer number. Further experiments are considered necessary in order to determine whether the differences observed are important or are within the limits of experimental error. A favorable influence was believed to be exerted by feeding the fats in the form of an emulsion.

Influence upon milk secretion of concentrated feeds rich and poor in fat when fed with different coarse feeding stuffs, G. FINGERLING (*Landw. Vers. Stat.*, 64 (1906), No. 4-5, pp. 299-412).—In these experiments, conducted with 2 goats, the substitution of rice meal rich in fat for barley feed poor in fat increased both the absolute yield of fat and the percentage of fat in the milk. This effect was considered due to a specific influence of the food fat upon the milk fat, and this was more apparent as the difference in the fat content of the 2 rations was increased.

By feeding a concentrated feeding stuff rich in fat along with an unsuitable coarse feeding stuff, such as hay which had been subjected to the effects of rain, it was possible to increase the yield of milk fat up to or above that produced by normal hay supplemented by a concentrated feeding stuff poor in fat, the ration so composed having an average fat content. It is believed that this result would prove of practical value if confirmed by experiments with cows.

In confirmation of earlier results obtained by the author (*E. S. R.*, 17, p. 70) the experiments showed the importance for milch cows of the aromatic, stimulating, or condimental substances normally present in sufficient quantities in feeding stuffs. When deficient, however, as in weathered hay, they can best be supplied by the addition of normal hay, or occasionally by seeds like fennel and anise, rather than by the use of the commercial condimental stock foods.

On the influence of feeding cocoanut cake upon the composition of butter fat with special reference to the Polenske number, M. SIEGFELD (*Milchz. Zentbl.*, 2 (1906), No. 7, pp. 289-295).—Tests made with 7 cows showed that feeding cocoanut cake exerted no apparent influence upon the Reichert-Meissl number but increased slightly the Polenske number and influenced to a much more marked extent the saponification number, iodine number, and the average molecular weight of the nonvolatile fatty acids.

First annual report of grade dairy herd, R. S. SHAW and A. C. ANDERSON (*Michigan Sta. Bul.* 238, pp. 161-176, pl. 1, figs. 4).—In 1904, the college purchased a grade dairy herd of 20 cows and planned to breed 5 cows and their female progeny to pure-bred Jersey bulls, 5 to Holstein, 5 to Guernsey, and 5 to Shorthorn bulls.

This bulletin is a report on the milk and butter production and the food consumption of this herd for the first year of the experiment. The average production of the herd for the year was 6,258.9 lbs. of milk and 298.25 lbs. of butter. Eliminating the poorest cow, which produced only 1,205 lbs. of milk and 48 lbs. of butter, the remaining 19 cows averaged 6,525 lbs. of milk and 311.4 lbs. of butter. The average profit per cow over cost of feed was \$36.58. The poorest cow was kept at a loss of \$9.88 and the best at a profit of \$60.29. An account of the feeding and management of the herd is given and illustrations of 4 of the cows are included.

Testing individual cows, H. A. HOPPER (*Illinois Sta. Circ.* 102, pp. 40).—This circular, which emphasizes the importance of studying the production of individual cows, contains records for one year of 18 dairy herds in Illinois, including 221 cows.

The average production was 5,616.99 lbs. of milk and 226.63 lbs. of butter fat. The best herd averaged 350.17 lbs. of butter fat and the poorest 142.05 lbs. The best 10 cows averaged 388.75 lbs. of butter fat and the poorest 10, 109.42 lbs. It is believed that at least one-third of the cows in the ordinary herds are practically unprofitable. A marked improvement was observed in herds where grading had been practiced. It was found possible to remove 5 cows from a herd of 10 and thereby increase the profit \$7.62 per head.

Butter tests with Shorthorn and Jersey cows, J. H. BURTON (*Jour. Bd. Agr. [London]*, 13 (1906), No. 4, pp. 193-200).—Ten Jersey and 6 Shorthorn cows on an average were tested once or twice a month from November, 1900, to July, 1904, the total number of tests being 86. A test consisted in taking 50 lbs. of the mixed milk of each breed, separating it, churning the cream after 2 days and determining the amount of butter produced.

On an average 1 lb. of butter was made from 27.92 lbs. of Shorthorn milk and 19.09 lbs. of Jersey milk. In these tests the Shorthorns produced 650 gal. of milk and the Jerseys 500. The relative profits of the 2 breeds are discussed from various standpoints. Under the local conditions of the experiments the Jerseys

were not considered profitable, as the extra return in butter was more than compensated by greater barrenness, a higher death rate from tuberculosis and milk fever, and other causes.

Dairy herd records, J. H. GRISDALE, R. ROBERTSON, and S. A. BEDFORD (*Canada Expt. Farms Rpts.*, 1905, pp. 51-61, 287, 288, 343).—Records are given of 35 cows at the central experimental farm, 22 cows at the experimental farm for the Maritime Provinces, and 10 cows at the experimental farm for Manitoba. At the central experimental farm tests were made of the feeding value for cows of a by-product from distilleries and of 2 cereal food by-products. A test was also made of feeding refuse apples to dairy cows, the results showing a slight increase in the rate of milk production when apples were fed as compared with a considerable decrease when apples were not fed.

Dairy herd, G. H. TRUE (*Nevada Sta. Rpt.*, 1905, pp. 42-44).—Records of 7 cows for 1 year and 4 cows for short periods are reported.

Story of Rose and Queen, W. J. FRASER, (*Illinois Sta. Circ.*, 103, pp. 4, figs. 2).—The first cow mentioned produced on an average for 10 years 384 lbs. of butter fat per year at an annual profit of \$56, while the second cow produced only 152 lbs. of butter fat per year for 6 years at an annual loss of \$2. These two records are discussed with reference to conditions prevailing among dairy herds in Illinois.

On the fat content of milk and its variations, E. UJHELYI (*Milchz. Zentbl.*, 2 (1906), No. 7, pp. 303-313).—The data collected by the author show that the milk produced in Hungary contains on an average about 3.8 per cent of fat. That feeding has no practical influence upon the percentage of fat in milk is considered as shown by the similarity in the milk from small farms and large estates. A monthly or seasonal variation in the fat content of milk is attributed to the stage of lactation. The poorest milk was obtained in March and April and the richest in October, November, or December.

Some causes affecting the profits of dairying, F. S. COOLEY (*Mass. Crop Rpt.*, 19 (1906), No. 2, pp. 28-36).—The subjects discussed include the kind of cows kept, the manner of replacing cows in dairy herds, the use of condimental feeding stuffs, causes of variation in the quality of milk, and the value of milk-test associations. Experimental evidence is cited in support of the views presented. The general use of condimental feeds is stated as acting adversely on the profits of the dairy.

Contribution to the study of the soluble proteids of milk, LINDET and L. AMMANN (*Rev. Gén. Lait*, 5 (1906), No. 16, pp. 361-371).—According to the authors, milk contains a soluble compound of casein and calcium phosphate designated calcium phosphocaseinate. Rennet, salts, alcohol, and acetic acid precipitated only a part of this compound, which is accordingly believed to exist in milk in solution as well as in a colloidal state.

Milk therefore contains 2 soluble albuminoids, albumin having a rotary power of -30° and calcium phosphocaseinate having a rotary power of -116° . The rotary power of the total albuminoids in the samples of milk examined varied between -62 and -74° . Based upon this difference in rotary power a method for determining approximately the quantity of albumin in milk is suggested and the results of a number of determinations are reported.

The authors attempt to refute the theory of Hammarsten that under the influence of rennet casein is transformed into paracasein insoluble in the presence of calcium salts and a soluble proteid representing about 10 per cent of the total nitrogenous material, on the grounds that the serum obtained by curdling milk with rennet contains less albuminoid matter than serum obtained by filtration through kaolin, and moreover, that the rotary power of the proteids not

affected by coagulation with rennet is the same as that of the soluble proteids in the milk. Coagulation is believed to be explainable only as a physical phenomenon.

The globulin of milk, L. MOROCHOWETZ (*Physiol. Russe.* 4 (1906), No. 68-74, pp. 48-96).—This is an extended review of the literature of milk proteids, all of which are considered by the author products of one and the same substance, designated lactoglobulin.

Upon the reduction of methylene blue by cow's milk, E. P. CATHCART (*Jour. Hyg. [Cambridge]*, 6 (1906), No. 3, pp. 300-303).—Raw milk decolorizes a mixture of formalin and methylene blue, depending upon the action of catalase in the milk. As this ferment is destroyed by heating to 65 to 70° C., this test, known as Schardinger's, serves well to differentiate between heated or boiled milk and raw fresh milk. It has been suggested by H. Smidt that a further use might be made of this test as a means of determining the degree of bacterial contamination of milk.

In studying the possibilities of this test the author ascertained that in order to get reliable and constant figures a very definite temperature must be employed. A rise in the temperature of the water bath from 40° to 50° was found to cause a diminution of practically 50 per cent in the time required for reduction. Another possible source of error arises from the fact that the catalase is found almost completely in the cream and hence a sample taken from the bottom and another from the top layer of milk that has been allowed to stand for some time would show a marked difference in results. This reaction is also affected by heat and the age of the milk, the latter due probably to the increased bacterial content. Earlier experiments in which the author cooperated showed that the reducing action of organisms varies to a marked degree.

In view, therefore, of the many possible sources of error the author considers this test as a means of estimating the bacterial contamination of milk too delicate for ordinary use, but that it might possibly be of value in a large laboratory where the various sources of error could be readily eliminated.

Quality of milk affected by common dairy practices, W. A. STOCKING, JR. (*Connecticut Storrs Sta. Bul.* 42, pp. 62-90, figs. 2, diagrams, 8).—This bulletin gives the results of a large number of experiments made to determine the effect upon the bacterial content of milk of some common dairy practices, such as feeding dry feeding stuffs at milking time, wiping off the cows with a damp cloth or brushing them at milking time, rejecting fore milk, etc.

The bacterial content of the milk was greatly increased by giving dry feeds just before or at milking time. This was more marked in the case of corn stover than hay or grain. Wiping the flanks and udder of the cow with a damp cloth just before milking was very efficient in reducing bacterial contamination, while brushing the cows at this time increased the germ content of the milk. Thorough stripping reduced the number of bacteria found in the milk at the next milking. Rejecting the fore milk reduced slightly the germ content of the remaining milk, but the difference was so small that the practice is considered as probably of value only where an extremely low germ content is desired.

Several experiments were made to determine the extent to which individual milkers affect the germ content of the milk. Five students trained in dairy bacteriology and the production of clean milk were compared with 2 regular milkers. Although stable conditions were identical and the same procedure was followed in each case, there was an average difference of 1,932 bacteria per cubic centimeter in favor of the students. A college graduate in charge of the dairy herd was also compared with the regular milkers. In this case the difference in the bacterial content of the milk as an average of 19 tests was 14,650 bacteria

per cubic centimeter in favor of the college graduate. The differences are accounted for only by the difference in the care exercised by the individual men in their work.

The motile and nonmotile aerobic gas-producing bacteria in milk, T. GRUBER (*Centbl. Bakl. [etc.], 2. Abt., 16 (1906), Nos. 20-21, pp. 654-663; 22-23, pp. 711-719*).—Descriptions are given of 28 strains of aerobic gas-producing bacteria belonging to the *Bacillus coli* and *Bacterium aerogenes* groups, compared and classified according to morphological and cultural characteristics.

The motile organisms were not uniformly peritrichous and hence the designation *Pseudomonas coli* is preferred to *Bacillus coli*. Cultural characteristics, especially the growth on gelatin plates, were found insufficient to distinguish the coli and aerogenes groups. Organisms in both groups were found capable of producing indol and nitrites. The gas-producing properties of the 2 groups permit the recognition of clearly defined subgroups, but do not permit of a sharp distinction between the organisms of the 2 groups. The characteristic so-called stable odor was produced on agar cultures and in fermented milk by the individual organisms of both groups.

A contribution to the bacteriology of milk, A. MACCONKEY (*Jour. Hyg. [Cambridge], 6 (1906), No. 3, pp. 385-407*).—Bacteriological studies were made of organisms isolated from milk as sold for domestic use and from milk obtained directly from the cow. The results obtained are reported in detail and support the general opinion that gas-forming bacteria are not normally present in milk, but that they gain access to it through want of care and cleanliness in milking and handling the milk.

No gas-forming organisms were found in samples drawn directly from the cow. It is considered practicable to obtain milk containing when freshly drawn less than 1,500 organisms per cubic centimeter and with no gas-forming organisms in at least 50 cc. The presence of gas-forming organisms is considered as showing fecal contamination. Those most frequently found in fresh milk were *Bacillus oxyptocus perniciosus*, *B. neapolitanus*, and *B. coli communis*, while those appearing at a later stage were *B. clouca* and *B. luctis aerogenes*. Out of 107 non-chromogenic lactose fermenting organisms isolated from milk only one gave the reaction of *B. acidi lactici*.

In the routine examination of water and food stuffs for the identification of organisms the author would substitute the fermentation of dulcitol, adonit, and inulin, and Voges and Proskauer's reaction for the character of the growth on nutrient gelatin, action on milk, formation of indol, fermentation of glucose, and action on neutral red now generally employed.

A bacteriological study of the certified milk of Philadelphia, A. H. STEWART (*Amer. Jour. Med. Sci., 131 (1906), No. 4, pp. 625-635*).—The bacteriological standard of the milk commission of the Pediatric Society of Philadelphia requires that milk to be certified must not contain injurious organisms nor more than 10,000 bacteria per cubic centimeter.

Five dairies furnish certified milk. Samples of milk from these dairies were collected at frequent intervals from July, 1904, to August, 1905, and examined for pus cells and bacteria. The results showed that 57.4, 16.5, 36.5, 35, and 23.1 per cent of the samples of the 5 dairies respectively were below standard. Streptococci were occasionally present. The number of pus cells ranged from 100 to nearly 300,000 per cubic centimeter, the number usually being well up into the thousands. The milk of one dairy which guaranteed a lower bacterial count than 5,000 per cubic centimeter was below standard in 81.2 per cent of the 16 samples examined.

The author states that most of the certified milk is stored for 24 hours in Philadelphia before delivery and when examined at the end of this period almost

none complies with the standard. While admitting that the bacterial counts of the certified milks were rather disappointing, the author believes that these milks are probably among the best produced in this country. With the present equipment of railroads, a standard of 10,000 bacteria per cubic centimeter is believed to be too hard to attain. Suggestions are made for the improvement of present conditions.

On the influence of high carbon dioxid pressure on the bacteria in water and milk, W. HOFFMANN (*Arch. Hyg.*, 57 (1906), No. 4, pp. 379-400, fig. 1).—Subjecting water to a carbon-dioxid pressure of 50 atmospheres for 24 hours prevented the development of bacteria. The same was also true of water inoculated with typhoid, cholera, and dysentery organisms and subjected to the same pressure for 3 hours.

Milk treated in the same manner for 24 hours at 56° showed a precipitation of the casein. The bacteria, however, were capable of growth after being subjected to these conditions. Milk obtained under hygienic precautions and subjected to carbon-dioxid pressure remained sweet for 24 to 48 hours longer than the same milk not subjected to pressure. In diluted serum agglutinins were not injured by the influence of moderate pressure for 48 hours, though bacterial development was checked or prevented.

The preservation of milk, especially with hydrogen peroxid, A. BABES (*Abs. in Rev. Gén. Lait*, 5 (1906), No. 16, pp. 381, 382).—The author argues that hydrogen peroxid is superior to formaldehyde as a means of preserving milk to be used for the purpose of immunization against tuberculosis according to the method of von Behring.

Whole milk, skim milk, buttermilk, and cream, 1906 (*Lab. Inland Rev. Dept. [Canada] Bul.* 121, pp. 45).—Of 319 samples of whole milk analyzed, 45 were pronounced adulterated and 85 doubtful. This was more unfavorable than the results obtained in previous years. Twenty-nine samples of cream examined showed percentages of fat ranging from 12.63 to 33.51. The author believes that the following standard should be established in Canada: Whipping cream not less than 25 per cent of fat, and table cream not less than 17.5 per cent.

Further bacteriological investigations of the butter of Stuttgart, A. REITZ (*Centbl. Bakt. [etc.]*, 2. Abt., 16 (1906), Nos. 22-23, pp. 719-733; 25, pp. 776-794, pl. 1, *dgm.* 1).—The earlier investigations (E. S. R., 17, p. 1109) were conducted for the purpose of determining the presence of tubercle bacilli in butter. In the present investigations 30 samples of butter were examined for the presence of typhoid and diphtheria bacilli, negative results being obtained.

Typhoid bacilli added artificially to butter made from sweet cream were found alive at the end of 10 days, but not after 15 days. In butter made from sour cream the typhoid bacilli were alive after 7 days, but not at the end of 10 days. The total number of bacteria varied between 9,000,000 and 40,000,000 per gram. It is believed that insufficient attention was paid to pasteurization. For the determination of the total number of bacteria, gelatin was preferred to agar. During the first few days the bacterial content of the butter decreased, after which it increased rapidly for 2 to 3 weeks, when it was 2 to 3 times as great as at the beginning. The numbers then decreased. The species of bacteria found which were considered of special importance were *Bacterium coli commune*, *Streptococcus pyogenes*, *B. prodigiosum*, species of Actinomyces and Saccharomyces, and molds. The last 3 groups were considered as having a marked influence on the rancidity of the butter.

An extended bibliography of this subject is appended to the article.

Investigation of salt, A. HESSE (*Milchw. Zentbl.*, 2 (1906), No. 7, pp. 295-302).—Analyses of 62 samples of dairy salt representing the different brands in

common use in Mecklenburg are reported, with comments upon the influence of the different impurities found in salt upon the quality of butter.

Contribution to the analysis of cheese, O. JENSEN and E. PLATTNER (*Ztschr. Untersuch. Nahr. u. Genussmitl.*, 12 (1906), No. 4, pp. 193-210).—The authors are endeavoring to ascertain if differences capable of recognition by chemical methods exist between normal and faulty cheese. In this article the methods of analysis employed are described and analyses of 10 Emmenthal cheeses of different quality, 1 normal Cheddar cheese, and 1 old Backstein cheese are reported and discussed in detail, without general conclusions being drawn.

Investigations on the propionic fermentation in Emmenthal cheese, E. VON FREUDENREICH and O. JENSEN (*Ann. Agr. Suisse*, 7 (1906), No. 4, pp. 221-242, pls. 2).—The results of the investigations show, according to the authors, that the greater part of the propionic acid found in Emmenthal cheese is formed by specific ferments at the expense of the calcium lactate resulting from lactic fermentation. The process is represented by the following equation:

Several of the propionic acid ferments are described. The carbon dioxide liberated in the fermentation is considered the principal cause of the holes formed normally in Emmenthal cheese. Outside of the propionic-acetic fermentation there occurs often a pure acetic fermentation of the calcium lactate, due as much to propionic ferments as to lactic ferments.

Investigations on the butyric fermentation in Schabzieger cheese, E. VON FREUDENREICH and O. JENSEN (*Ann. Agr. Suisse*, 7 (1906), No. 4, pp. 243-252).—The origin of the butyric acid in the fermentation of this cheese was studied bacteriologically.

The authors isolated 2 bacilli which attack casein feebly and lactose vigorously and produce butyric, propionic, and formic acids in practically the proportions found in this cheese. The organisms are not believed to have anything to do with the ripening of the cheese. The butyric-propionic-formic fermentation in this cheese, like the propionic-acetic fermentation in Emmenthal cheese, is believed to be an accessory process independent of the ripening of the cheese, but important as regards the production of aroma.

Bacteriological studies of the abomasum and rennet, J. THÖNI (*Landw. Jahrb. Schweiz*, 20 (1906), No. 3, pp. 181-242, figs. 2).—Bacteriological studies of the fourth stomach, the whey used in preparing rennet, and natural rennet are reported, and many of the micro-organisms isolated, including some new species, are described.

The fourth stomach, used in the preparation of rennet, was found in general to have a fairly constant bacterial flora consisting of indifferent, injurious, and beneficial micro-organisms. The indifferent forms included cocci, species of *Sarcina*, and *Streptothrix*, *Bacterium fluorescens*, hay bacillus, potato bacillus, and a new species of *Bacterium*. The injurious organisms included *Bacterium coli*, *B. lactis aragones*, and 2 new species of *Bacillus*. The useful organisms included lactic-acid bacteria, propionic acid-producing organisms, and *Mycoderma*. Among the new organisms described 2 are considered of special interest—one designated *Bacillus* 4 or *B. acidi acetici*, an anaerobic acetic acid-producing organism, and *B.* 5, an organism found to produce late fermentation in cheese.

The different parts of the rennet stomach showed marked differences in the bacterial content. The pyloric end and fatty parts particularly showed high numbers of bacteria, consisting for the most part of the injurious forms. The whey used in the preparation of rennet was found to be poor in bacteria, and the few bacteria that were present were found to be without influence. The

indifferent forms were found to disappear quickly from the rennet, while the 2 other groups developed more or less rapidly in proportion to the numbers originally present in the stomach.

It is believed that in practice the growth of the beneficial bacteria may be favored by the observance of suitable precautions, such as the cleaning of the stomach, the discarding of the pyloric and fatty portions, which harbor especially the injurious organisms, and the keeping of the rennet at about 30° C. When prepared in this way, the beneficial organisms generally reach their highest numbers in about 2 to 3 days. Through the addition of a mixed culture of *Bacillus casei* ϵ and *Mycoderma* in the preparation of rennet it is believed that the practical value of the rennet is increased.

VETERINARY MEDICINE.

Report of the veterinary division, T. FLINTOFF (*Orange River Colony Dept. Agr., Ann. Rpt., 1 (1904-5), pp. 17-43, pls. 3*).—An account is presented by the veterinary staff of the Orange River Colony stock inspectors of the prevalence of various animal diseases in the colony, which are classified according to the animal affected. In horses particular attention is given to glanders, horse sickness, and osteoporosis; in cattle, to foot-and-mouth disease, African coast fever, and tuberculosis; and in pigs, to hog cholera and swine erysipelas. A statement is given regarding the number and condition of the government stallions in the colony.

A new disease in goats, called contagious catarrhal fever or goat distemper, is reported by H. K. Tasker. Goats affected with this disease show greatly swollen ears followed after 5 to 7 days by discharge from the nostrils and eyes. The disease reaches the crisis in about 14 to 18 days. At the height of the disease the animal will stand still much of the time, being unable to move except with a staggering gait. The period of incubation is 5 to 7 days. The disease appears to be contagious, although this point is not definitely determined.

The cause of halisterisis of the bones and therapeutic notes, KLIMMER and SCHMIDT (*Monatsh. Prakt. Tierheilk., 17 (1906), No. 11-12, pp. 481-517*).—The term halisterisis means deficiency of mineral matter and is used in preference to osteomalacia for the reason that it indicates the cause of the disease rather than the final condition observed in the bones as the result of the disease. The symptoms of halisterisis are described in great detail as observed in cattle, hogs, goats, dogs, and other animals.

In all cases the disease commonly referred to under the name rickets was due to the deficiency of mineral matter in the feed. On the basis of physiological experiments a table was prepared indicating the lime requirements of different domestic animals, according to their size, age, and sex. Other tables are presented showing the percentage of lime and phosphoric acid in a great variety of food stuffs under different conditions. The literature on this subject is reviewed in connection with the bibliography of 127 titles. The authors come to the conclusion that halisterisis, being due to an insufficient amount of mineral matter in the feed, should be treated by the addition of suitable bone salts and phosphate of lime.

Immunity in tuberculosis, S. FLEXNER (*Pop. Sci. Mo., 69 (1906), No. 3, pp. 229-247*).—The more striking results obtained by investigators with regard to tuberculosis are briefly outlined with particular reference to the controversy started by Koch and to recent work of immunizing cattle and other animals to tuberculosis.

It is believed that no lasting or effective immunity toward tuberculosis can be obtained by the use of tubercle bacilli killed by heat or any other agency.

The artificial production of immunity to tuberculosis appears to rest upon the use of attenuated living tubercle bacilli. The possible danger from the use of human tubercle bacilli in immunizing cattle is also discussed.

Human and bovine tuberculosis, N. RAW (*Brit. Med. Jour.*, 1906, No. 2381, pp. 357, 358).—In a continuation of his studies on the relationship of human and bovine tuberculosis, the author finds repeated confirmation of his previous conclusion that there are two forms of tubercle bacilli, but that man is subject to both and may readily become infected particularly in childhood by drinking tuberculous milk. The author believes that human tubercle bacilli do not attack the ordinary lymphatic glands of the body but produce lesions chiefly in the lungs. It is argued, therefore, that in most cases where the mesenteric glands are affected the tubercle bacilli are of bovine origin.

Experimental transmission of tuberculosis from man to cattle, A. EBER (*Ztschr. Fleisch u. Milchhyg.*, 16 (1906), No. 7, pp. 218-223).—The material used in the inoculation experiments reported in this paper came from tuberculous mesenteric glands of human origin.

It is found possible by using this material in the inoculation of a bovine animal and subsequently making a reinoculation from this animal into another bovine animal to produce an acute miliary tuberculosis resulting in death within 6 to 7 days. Similarly when the material was first passed through a guinea pig and subsequently used for the inoculation of cattle death resulted within 51 days. In a third case, bacilli of less virulence were obtained.

It appears from these experiments that tubercle bacilli may be obtained from human cases of tuberculosis which are equally as pathogenic as bovine bacilli for cattle. The author argues, therefore, against the proposition of separating human and bovine tubercle bacilli on the basis of differences in virulence.

The origin of tuberculosis, J. BONGERT (*Deut. Tierärztl. Wchschr.*, 14 (1906), No. 21, pp. 241-244).—During the investigations carried out by the author it appeared that a diffuse tuberculous infiltration of the intestinal mucous membranes is often observed in cattle, and this trouble is caused by greatly attenuated tubercle bacilli. These bacilli show great differences in their morphological, cultural, and pathogenic properties. The author objects to the statement of Schütz that tuberculosis of cattle is always caused by the bovine type of tubercle bacilli for the reason that the type found in cattle is by no means constant. For example, highly virulent and greatly attenuated bacilli may be found in the same case of tuberculosis.

The relation between human tuberculosis and pearl disease of cattle, LYDIA RABINOWITSCH (*Berlin. Klin. Wchschr.*, 43 (1906), No. 24, pp. 784-788).—Summing up her investigations on the interrelation of human and bovine tuberculosis, the author comes to the conclusion that man may become infected with pearl disease, but that the frequency of such infection is still undetermined. A determined warfare against bovine tuberculosis is, therefore, necessary not only in the interest of animal industry, but for the protection of human health.

The nutrition of animals and tuberculosis, D. BONORA (*Gior. R. Soc. ed Accad. Vet. Ital.*, 55 (1906), No. 20, pp. 480-484).—The relationship between the nutrition of animals and the development of tuberculosis is briefly discussed. It is maintained that a rational system of feeding in which a liberal and well-balanced ration is used should lie at the foundation of any system devised for the control of tuberculosis. This recommendation was made in the belief that properly nourished animals are less susceptible to tuberculosis than those which are suffering from malnutrition.

The pathogenesis of tuberculosis, H. VALLÉE (*Compt. Rend. Acad. Sci. [Paris]*, 142 (1906), No. 20, pp. 1101-1103).—The author has continued his

studies on the comparative rôle of the digestive and respiratory organs as the primary location of tuberculous infection. It appears that in many cases in which the lungs and bronchial glands are affected most extensively, the original infection was located in the intestines and was due to ingestion of tuberculous material with the feed. The author believes that in this respect calves and children behave in the same manner toward tubercle bacillus. According to the author's investigations the source of infection must remain doubtful even in cases where the lungs and other respiratory organs are the only parts affected, for cases which are apparently of purely pulmonary origin may nevertheless trace their source of infection through the intestines.

The virulence of lymphatic ganglia in tuberculous animals, H. VALLÉE (*Compt. Rend. Soc. Biol. [Paris]*, 60 (1906), No. 19, pp. 911-913).—A number of authors have called attention to the fact that lymphatic glands of apparently normal condition may contain tubercle bacilli. This fact has been noted most frequently in connection with experiments in immunizing cattle against tuberculosis by the use of human tubercle bacilli. In these cases the glands of the immunized cattle contained tubercle bacilli for a long time after apparent recovery from vaccination. The author finds that the mesenteric as well as other lymphatic glands of cattle, after tuberculous infection from any source, may contain virulent tubercle bacilli without showing any abnormal condition. It is concluded, therefore, that none of the lymphatic glands in a tuberculous animal may be considered as free from tubercle bacilli. The bearing of these investigations on the utilization of tuberculous meat is apparent.

Combating tuberculosis of cattle, J. POELS (*Tijdschr. Veeartsenijk.*, 33 (1906), Nos. 8, pp. 477-496; 9, pp. 535-548).—Attention is called by the author to the great importance of a more thorough clinical study of tuberculosis in order to be able to recognize by the physical symptoms the first occurrence of tuberculosis in the lungs. It is believed that the extensive use of tuberculin and the complete reliance of most veterinarians upon this reagent have led to some neglect in the study of physical symptoms. The disease is admittedly more infectious when the lungs are attacked than when it is confined to other internal organs. The importance of being able to recognize the presence of the disease in the lungs is therefore obvious.

Four cases of equine tuberculosis on one farm, W. R. DAVIS (*Vet. Rec.*, 18 (1906), No. 925, p. 678, fig. 1).—The extensive development of tuberculosis was observed in a 4-year-old mare which had to be killed on account of the presence of the disease. Her colt likewise developed tuberculosis, and also two other horses on the same premises. The author calls attention to the relative infrequency of tuberculosis in horses, but notes the fact that there were 4 cases of the disease in horses during a period of 3 years on a small farm on which the owner never had more than 6 horses at a time.

A study of avian tuberculosis, V. A. MOORE (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 1 (1906), No. 4-5, pp. 333-340).—A short account is given of the experiments carried on by the author with regard to the nature and transmissibility of tuberculosis in the fowl. It was found by feeding and inoculation experiments that avian tuberculosis can not always be transmitted to experimental animals, and also that human and bovine tuberculosis are not always easily transmitted to fowls. All of the author's experiments along this line gave negative results.

The immunity of *Galleria mellonella* toward tubercle bacilli, S. METALNIKOFF (*Compt. Rend. Soc. Biol. [Paris]*, 60 (1906), No. 11, pp. 518, 519).—On account of the fact that tubercle bacilli are surrounded with a waxy envelop which appears to serve the purpose of protecting them against digestion and

destruction by the fluids of the animal organism in which they are found, the idea originated of determining whether animals which naturally digest wax are immune to the tubercle bacillus.

For this reason the bee moth was chosen as the most suitable species since it lives largely on beeswax. The insect was found to be absolutely immune to tuberculosis. When tubercle bacilli were inoculated into the larvae of bee moths, the bacilli were rapidly destroyed, being transformed within a few hours into a brownish pigment-like mass. This destruction was accomplished partly by the ordinary leucocytes and partly by giant cells. It was found in experiments on guinea pigs that these animals when vaccinated with the blood obtained from bee moth larvae were rendered highly resistant to tubercle bacilli. Further studies along this line are promised.

A biological method for demonstrating anthrax in practice, E. JACOBSTAHL and F. PFELSDORF (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 1 (1906), No. 2-3, pp. 102-123, fig. 1).—For the practicing veterinarian as well as for officials of the government veterinary service a rapid method of diagnosing anthrax is an important desideratum.

In order to obtain a reliable diagnosis, it is desirable to hasten the formation of spores as much as possible, and according to the authors' experience this may best be accomplished by placing the suspected material on a rod of gypsum previously moistened with bouillon or water. The bacteria which would naturally come into account in making a differentiation by this means are spore-forming anaerobes and nonspore-forming and spore-forming aerobes.

In making the diagnosis according to the method proposed by the author, the rod of gypsum is removed from the test tube and placed in clean water for about a minute, after which it is returned to the test tube. The amount of water in and on the piece of gypsum is sufficient to moisten the cotton placed at the lower end of the gypsum rod. The material for testing is preferably to be taken from the jugular vein, spleen, or blood clot in the heart, after which the suspected material was placed on the gypsum rod, the whole test tube enclosed in a shipping box and sent to the laboratory.

According to the extensive experience of Marxer, Ostertag, and others, this method yields positive results in many cases where others have failed for the reason that the spores develop very rapidly if the material contains anthrax bacilli.

The simultaneous inoculation method for anthrax, G. SOBERNHEIM (*Berlin. Tierärztl. Wechschr.*, 1906, No. 12, pp. 233-235).—The method of combined inoculation with serum and cultures has found application in a large number of cases during the past year. One firm in Germany prepared over 200,000 doses, a large part of which was shipped to Argentina and Uruguay.

Notes are given on the distribution of anthrax in these South American countries and statistics are presented regarding the effectiveness of the method as shown by reports based on about 300,000 animals. These reports indicate that the method yields very satisfactory results. In the nearly 300,000 cases in which the combined inoculation has been applied not a single animal has died as the result of vaccination and the disease has been effectively checked and controlled wherever the method has been thoroughly applied.

Texas or tick fever and its prevention, J. R. MOHLER (*U. S. Dept. Agr., Farmers' Bul.* 258, pp. 45, figs. 6).—The material contained in this bulletin is essentially a condensation of Bulletin 78 of the Bureau of Animal Industry (E. S. R., 17, p. 1190).

The treatment of cases of bloody urine in cattle with hemoglobin, EVERS (*Berlin. Tierärztl. Wechschr.*, 1906, No. 19, p. 364).—Hemoglobin is dissolved in a 20 per cent itrol solution at the rate of 1 gm. to 5 cc. and should be used

within 24 hours after mixing. When administered hypodermically, it causes no bad effects at the point of inoculation. The author reports that he has used this remedy on more than 40 experimental animals, including horses, cattle, and sheep, in some cases administering as much as 500 cc. Considerable benefit is always manifested from the use of hemoglobin in cases where the amount is below normal.

Recurrence of parturient paresis, KAHN (*Berlin. Tierärztl. Wechschr.*, 1906, No. 17, p. 322).—In the experience of the author as well as that of other investigators, the recurrence of parturient paresis soon after an apparent recovery is very rare. Notes are given on a case in which air infiltration was used in the treatment of the disease. The cow recovered within a few hours, but suffered a relapse 5 days afterwards. Air infiltration into the udder was again administered, after which recovery took place without a recurrence of the disease.

Parturient paresis, GEBAUER (*Berlin. Tierärztl. Wechschr.*, 1906, No. 20, pp. 377-379).—In a brief review of the literature of this subject the author gives particular attention to the investigations of Hess and Zehl. The evidence thus far presented for considering parturient paresis as an infectious disease is not very strong. The most characteristic and pronounced symptom is cerebral anemia. The author believes that the often-observed cessation of the milk secretion in cases of this disease is an attempt on the part of the organism to compensate for the disturbed circulation. In one instance the author observed a case in which the symptoms were identical with those of parturient paresis and the infusion of air into the udder caused a prompt improvement, but later serious symptoms occurred and the animal was slaughtered. It was found in this case that the cerebral anemia was due entirely to a vaginal hemorrhage which had lowered the blood pressure.

Milk fever before parturition, GALLIER (*Bul. Soc. Cent. Méd. Vét.*, 83 (1906), No. 6, p. 153).—This disease, while always related to parturition, sometimes occurs before as well as after this event. Notes are given on a case which came under the author's observations. A complete recovery took place after the application of the Schmidt treatment.

The treatment of infectious vaginal catarrh of cattle, H. RAEBIGER (*Berlin. Tierärztl. Wechschr.*, 1906, No. 13, pp. 241, 242, figs. 4).—In the treatment of this disease considerable difficulty has been experienced on account of the merely temporary effect of ordinary antiseptic washes.

The author devised a syringe, by means of which dry antiseptic materials and also salves could be injected. The results obtained from the use of this apparatus have been very satisfactory. It is considered, however, that in all cases in which the uterus is also affected the cow should be fattened and sold for beef since, if she is kept in the herd, it is practically impossible to prevent the further spread of the disease.

The enzootic appearance of gangrenous vaginitis in cows, A. M. BERGMANN (*Fortschr. Vet. Hyg.*, 4 (1906), No. 1, pp. 1-6).—The disease occurs most frequently in connection with calving and attacks chiefly heifers and young cows. A brief account is given of the persistence of the disease from year to year in a badly infected herd. The cause of the disease is infection with the necrosis bacillus. In order to prevent infection of the milk of diseased cows, it appears to be necessary to make frequent use of lysol douches. This treatment should be applied immediately after parturition.

Notes on the enzootic occurrence of gangrenous vaginitis in cows, A. M. BERGMANN (*Svensk Vet. Tidskr.*, 11 (1906), No. 3, pp. 117-120).—Several cases of this disease have come under the observation of the author. The usual symptoms and pathological alterations are described. Quite satisfactory re-

sults were obtained by the thorough application of washes of chlorid of zinc in 10 per cent solution.

Poisoning of cattle by Lima beans, G. MOSSELMAN (*Ann. Méd. Vét.*, 55 (1906), Nos. 3, pp. 141-153; 4, pp. 205-215).—The seeds of various varieties of *Phaseolus lunatus* contain quantities of glucosid which is capable, after fermentation, of producing enough hydrocyanic acid to kill herbivorous animals which eat the beans.

According to experiments, 500 gm. of beans may be enough to kill a horse and if fed in larger quantities the result may be fatal even after cooking. Even the leaves of cultivated varieties were found to be toxic, but the toxicity varied greatly according to the age of the plants and the stage of vegetation. In cases where the plants or beans contained free hydrocyanic acid animals refused to eat them. This was found to be the case with rabbits and guinea pigs after allowing them to fast for 2 days. It is believed by the author that not all varieties of *P. lunatus* are poisonous, and it is suggested that this matter may depend somewhat on the soil and nature of the cultivation.

Mushroom poisoning in cows, HAGA (*Norsk Vet. Tidsskr.*, 18 (1906), No. 1-2, pp. 29, 30).—In a small herd of cows in Suldal, 2 animals died as a result of eating poisonous mushrooms, apparently *Agaricus muscarius*. The symptoms were those which are commonly described as occurring in man and developed with great violence. There was profuse diarrhea accompanied with brain symptoms. No opportunity was had for testing any remedial measures.

Larkspur and other poisonous plants, G. H. GLOVER (*Colorado Sta. Bul.* 113, pp. 24, pls. 8).—The losses from poisonous plants in Colorado are annually a serious drain on the stockmen. The station in cooperation with the Bureau of Plant Industry of this Department is investigating a number of problems connected with poisonous plants.

In the present report a general discussion is given of the factors which determine plant poisoning and particular attention is given to larkspur, death camas, water hemlock, lupines, and rubber plant. As remedies for larkspur poisoning the author recommends drenches with potassium permanganate and a hypodermic injection of atropin. Descriptive and biological notes are also given on death camas, water hemlock, and lupines, with brief notes on curative methods. The bulletin also contains a feature of practical importance to stockmen consisting of a synopsis of symptoms and treatment to be applied in the poisoning of cattle, horses, and sheep by different plants under different conditions.

Geel dikkop, R. PAINE (*Jour. Compar. Path. and Ther.*, 19 (1906), No. 1, pp. 5-8).—This disease, commonly known by its Dutch name, which means yellow thick head, affects chiefly Merino and Africander sheep and Angora goats.

The trouble usually appears in herds grazing on low land after a considerable rainfall. The head and ears swell greatly and a dropsical condition of these parts appears. The temperature often rises to 104° F. A certain percentage of cases may live for a week or more, but they usually end fatally. If no treatment is adopted, the swollen parts become dry, shrivel up, and crack. The general condition of jaundice is also observed. Most sheepmen believe that the disease may be prevented by removing the flock to high land where the disease is not prevalent and keeping the sheep corralled until after the dew is off in the morning.

When examined post mortem, affected sheep were found to show a general jaundiced condition, with a soft liver, inflammation of the gall bladder, and occasionally an enlargement of the spleen. Considerable benefit is to be derived from feeding the sheep on alfalfa and giving them plenty of good water. The average mortality is about 40 per cent. Occasionally the disease appears to be capable of transmission by inoculation, but the nature of the trouble is not well understood.

Bacteriological diagnosis of chronic swine plague, JUNACK (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 1 (1906), No. 2-3, pp. 153-166, fig. 1).—Data are given regarding the bacteriological diagnosis in a large number of cases of pure swine plague, combination swine plague and hog cholera, pure hog cholera, and intestinal catarrh of pigs. The bacteria obtained in these tests are enumerated.

It appears from the author's study that in case of the prevalent chronic form in swine plague a negative bacteriological finding does not decide the matter for the reason that the demonstration of *Bacillus suiscepticus* fails in about one-third of the chronic cases of the disease. In such cases the anatomical findings and the infectiousness of the disease makes it possible to reach a diagnosis. Certain races of *B. suiscepticus* when cultivated on artificial nutrient media form short rods in addition to long threads and retain both of these forms when inoculated into other animals or maintained from generation to generation on artificial media.

Active immunization against hog cholera, M. PRETNER (*Berlin. Tierärztl. Wehnschr.*, 1906, No. 10, pp. 173, 174).—Hogs were inoculated intraperitoneally with the organism of hog cholera and subsequently an exudate was obtained from these hogs which, after sterilization, was used in testing its immunizing power on other hogs. Four parallel tests were made in each of which one animal was treated with this exudate and the other not. In all cases the immune animals remained healthy without any reaction. The author believes that his experiments justify the hope of obtaining a method of producing active immunity in hogs by means of an exudate caused by *Bacillus suispestifer*, but not containing bacteria.

Glanders: Its nature, distribution, and prevention, P. FISCHER (*Ohio Live Stock Assoc. Bul.* 6, pp. 9).—The successful control of glanders in the author's opinion depends upon the education of horse owners in an understanding of the dangers of this disease and in a thorough appreciation of the wide distribution of the disease and the danger of allowing infected horses to be utilized in any way which will bring them in contact with healthy horses. Attention is called to the danger of infection from glanders in unsanitary stables, blacksmith shops, and from public watering troughs.

The establishment of a simple basis for judging mallein reaction, FOTU (*Fortschr. Vet. Hyg.*, 3 (1906), No. 11, pp. 244-249).—The author summarizes a number of results obtained in the use of mallein for the purpose of determining the reaction which usually occurs in typical cases of glanders.

As a result of this study it is concluded that mallein is a suitable reagent for determining glanders in herds of horses at a comparatively small expense. At present, however, it is a difficult matter to establish an exact standard for the mallein reaction. In order that such a standard may be set up it is considered necessary to carry on experiments with horses artificially inoculated with glanders in order to be able to test them with mallein at periods of known length after the beginning of infection. Mallein must also be tested more extensively on horses known to be nonglanderous. It is considered desirable also to compare the mallein reaction with the results obtained by agglutination.

Malarial fever in horses, A. T. PETERS (*Nebraska Sta. Press Bul.* 22, pp. 7, figs. 3).—The symptoms and prevalence of this disease are briefly described. The disease has been observed in Nebraska since 1902 and has caused the death of many horses. Affected animals become gradually emaciated and the number of red blood corpuscles much reduced. The author did not succeed in obtaining cultures of any organism which might be considered as the cause of the disease. A parasitic worm was found in connection with the disease, and further study will be devoted to this parasite and to the possible occurrence of pathogenic bacteria,

Malaria in horses, G. J. BRICKMAN (*Svensk Vet. Tidskr.*, 11 (1906), No. 3, pp. 120-130, figs. 2).—Particular attention is given in this account to the etiology of malaria in horses. The blood parasite was found in the red blood corpuscles and produced, during the course of the disease, a sort of pernicious anemia in the blood of horses. The disease is accompanied with profuse sweating and the thorough application of arsenical treatment appears to relieve this symptom and otherwise check the course of the disease.

The occurrence and treatment of inflammation of the lumbar part of the spinal cord, KULL (*Ztschr. Veterinärk.*, 18 (1906), No. 8-9, pp. 353-356).—During the years 1904 to 1906 an infectious disease broke out among army horses and was referred to under the names infectious catarrh and inflammation of the lumbar portion of the spinal cord. The spinal affection was the more important part of the disease and is therefore retained as the more appropriate name. The disease was controlled by a thorough quarantine of all stalls in which infected animals had stood and by the use of antiseptic solutions in such connection. It was found possible to produce passive immunity of short duration against the disease by serum treatment.

Ill effects sometimes produced on horses and mules pastured exclusively upon alsike, M. JACOB (*Tennessee Sta. Bul.*, Vol. XVIII, No. 3, pp. 28-30, fig. 1).—A peculiar disease has been noted in certain parts of Tennessee as a result of pasturing too exclusively on alsike clover.

The disease affects only horses and mules and improvement takes place in mild cases as soon as the animals are removed from alsike pasture. The exact cause of the disease is not understood. The chief symptoms appear on the skin in the form of inflamed areas which are later sloughed off leaving sores. The eyes, tongue, mouth, and alimentary tract may also be affected. In cases where the skin only is affected, treatment is simple and consists in removing the animal from alsike pasture and treating sores with an antiseptic wash.

Recent investigations concerning rabies, L. PANISSET (*Rev. Gén. Méd. Vét.*, 8 (1906), No. 87-88, pp. 113-139).—The literature of this subject is critically discussed in connection with bibliographical references. Particular attention is called to the recent investigations undertaken for the purpose of determining the most satisfactory methods of diagnosing rabies in a rapid and reliable manner.

The course of rabies virus and antirabies vaccine, P. REMLINGER (*Compt. Rend. Soc. Biol. [Paris]*, 60 (1906), No. 12, pp. 573-575).—As a result of numerous experiments on laboratory animals it appears that rabies virus travels from the point of entrance into the organism toward the nerve centers along the peripheral nerves and that the antirabies vaccine passes toward the nerve centers in the lymphatic system. The results of vaccination, therefore, vary according to the relative rate of speed which these two substances take in their course toward the central nervous system.

The appearance of virulence in the saliva of rabid animals, J. NICOLAS (*Jour. Méd. Vét. et Zootech.*, 57 (1906), Apr., pp. 208-218; *Compt. Rend. Soc. Biol. [Paris]*, 60 (1906), No. 13, pp. 625, 626).—In the control of outbreaks of rabies among domestic animals it is of great importance to know as definitely as possible just when the saliva becomes virulent. For this purpose a number of inoculation experiments were made on goats, rabbits, and dogs. The virus in the saliva was found to be virulent from 4 to 6 days before the appearance of any symptom of the disease in dogs and goats and at least 4 days before the appearance of symptoms in dogs inoculated in the muscles.

A malignant infectious eye disease in fowls, RABUS (*Wchnschr. Tierheilk. u. Viehzucht.*, 50 (1906), No. 11, pp. 207, 208).—In a flock of 12 fowls, 8

developed symptoms of a contagious eye disease consisting in intense inflammation of the conjunctiva which became covered with a mucous or purulent material. Some of the worst cases were killed while the less developed cases were treated by means of silver nitrate at the rate of 1 part to 6 in water.

The disinfection of stock cars by means of aqueous formaldehyde solutions, J. SCHEINÜRER (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 1 (1906), No. 2-3, pp. accomplished by the most thorough spraying of cars with formaldehyde for the purpose of determining the effectiveness of this method in destroying thoroughly reached with the formaldehyde solution.

The strengths of formaldehyde used were 1, 1½, and 2 per cent. When these applications were made at relatively low temperatures the effect was not as good as could be desired. Better results were obtained when a higher temperature was maintained in the cars. A complete disinfection can not be accomplished by the most thorough spraying of cars with formaldehyde for the reason that cars are not constructed so that every crack and crevice could be thoroughly reached with the formaldehyde solution.

Disinfection by means of formaldehyde and potassium permanganate, J. G. CUMMING (*Rpt. Mich. Acad. Sci.*, 7 (1905), pp. 177-180).—Claims have been made that when formalin is poured over potassium permanganate, a rapid process of oxidation takes place which leads to the liberation of formaldehyde gas in large quantities.

This matter was tested by the author, and during his experiments 3,000 specimens of infected silk threads, cloth, and filter paper were exposed to various conditions of disinfection. The organisms used in these experiments included anthrax bacillus, typhoid bacillus, streptococci, and various other bacteria. In these experiments the permanganate process was compared directly with the regular distillation method recommended by Novy. The results obtained indicate that the permanganate process is not as useful as the distillation method, but that the former method is so simple that it may be used effectively and safely by a layman.

RURAL ENGINEERING.

Primer of irrigation, D. H. ANDERSON (*Chicago: The D. H. Anderson Pub. Co.*, 1905, pp. 257, pls. 16).—This is a volume which, according to the author, is intended to "lend aid to those who are beginners in irrigation farming."

In carrying out this idea the author considers his subject in its relation to other branches of agricultural science and takes up, in turn, the formation and qualities of soils, together with their treatment for alkali, etc.; plant foods and a simple exposition of the chemical processes involved in plant feeding; the tilling and laying out of land with special reference to irrigation farming; finally discussing in a popular way the more technical aspects of the subject, such as duty and measurement of water, pumps and irrigation machinery, etc. The author has compiled in a readable manner much information of value to those about to take up or already engaged in irrigation farming.

Investigation of irrigation practice in Oregon, A. P. STOVER (*U. S. Dept. Agr., Office Expt. Stas. Circ.* 67, pp. 30, figs. 4).—This circular covers the work done in Oregon by Mr. Stover in 1905. The methods of preparing land for irrigation and of applying water are discussed from the standpoint of the needs of Oregon rather than describing Oregon practice.

One of the most interesting features of the circular is the discussion of flood water or winter irrigation in the Butter Creek Valley, where the water

supply during the summer is extremely limited. Large quantities of water are applied to the land when the streams are high in the spring, and with this heavy irrigation three crops of alfalfa are raised and orchards are also successfully maintained. The success of this form of irrigation is attributed to the impervious subsoil and peculiar formation of the valley which prevents the ground water from draining out.

Seepage measurements were made in a number of canals, showing large losses. The efforts made to check these losses in the Irrigon Canal are described at some length. Plowing and harrowing the silt in the bottom of the canals was tried without beneficial effect. Later a homemade device called a chain puddler was tried, with good results, the seepage loss after the use of this puddler being less than half that before it was used. This puddler consists of heavy chains attached to the ends of a beam placed across the running gears of a wagon and extending across the ditch. The chain drags on the bottom of the ditch, tears up the vegetation on the bottom of the canal, and puddles the silt.

The circular gives directions for preparing land for applying water by various methods, together with estimates of the cost of these operations.

Irrigation in the North Atlantic States, A. J. BOWIE, JR. (*U. S. Dept. Agr., Office Expt. Stas. Bul. 167, pp. 50, figs. 7*).—This report includes data collected during July and August, 1905, in a study of irrigation as practiced in Maryland, Delaware, Pennsylvania, New Jersey, New York, Rhode Island, and Massachusetts.

The territory investigated lies in the humid district of the United States, where the annual rainfall is between 40 and 50 in. and where irrigation is not always necessary for the growth of crops and has been confined to truck farms and meadow lands. Truck farmers in the vicinity of large cities frequently use city water at a cost of \$1 to \$1.50 per 1,000 cu. ft., or \$44 to \$65 per acre-foot. In spite of this prohibitive price when compared with western practice, those farmers practicing irrigation in the district covered seem to find it profitable. This is probably due to the fact that the yearly value of the truck crops is estimated as being increased 30 to 50 per cent. "As the cost of irrigation usually lies between \$30 and \$100 per acre it is fair to assume an acreage profit of \$200 or more per acre due to irrigation."

A large number of irrigation plants in the States covered are described in detail and from the study the following conclusions are drawn:

"The irrigation of meadows and truck farms is an established and profitable practice in the North Atlantic States, while the profitable irrigation of field crops has not been demonstrated as yet.

"The methods employed are very expensive compared with western practice, but are the outgrowth of peculiar conditions and meet the requirement of very small applications of water.

"The quantity of water required by truck crops either as rain or irrigation is about 1 inch in depth every week, and in the light sandy soils generally used it should be applied in quantities not exceeding 1 inch at a time."

An underflow canal used for irrigation at Ogalalla, Nebraska, C. S. SLICHTER (*Engin. News, 56 (1906), No. 1, pp. 4, 5, figs. 6*).—The writer gives the results of an investigation of this canal made during 1905.

The canal excavation is about 12 ft. wide at the bottom and about 6,500 ft. in length, extending along the south bank of the South Platte River and reaching a total depth in its upper portion of 5 ft. below the bed of the river. This is the only successful instance of a large number of such constructions which have from time to time been tried, and in the present case the writer thinks success is due to the small size of the canal and the unusually large slope of the

river at the point in question. The percolation into the canal per square foot of percolating surface was found to be 0.01 to 0.02 gal. per minute per foot of head. These figures are said to be low, "due to the vegetation and slime that obstructs the sand through which water must pass, but it is mainly due to the fact that stratified gravels do not readily transmit water if the water must travel across or perpendicular to the direction of bedding."

The cost of construction and subsequent expenses for maintenance are found to be so large that the author expresses the opinion that a pumping plant consisting of a Corliss condensing engine and centrifugal pump would be more satisfactory.

Use of water in agriculture—a contribution to the study of irrigated meadows in the Vosges, M. R. OLRV (*Ann. Inst. Nat. Agron., 2. ser., 5 (1906), No. 1, pp. 233-382*).—A thorough study of a system of agriculture in the department of Vosges, France, corresponding more or less closely with that found on certain elevated plateaus of the western United States.

The systems of water distribution described are similar to those existing in many western States, and the same confusion and difficulty is experienced in the strict enforcement of priorities in times of drought, to remedy which the writer recommends irrigation associations between whom agreements shall be made to use water in turn for a period of 5 days each.

With regard to the quantity of water used the author finds that "In the great majority of cases the quantity of water used in the districts studied varies between 150,000 and 300,000 cubic meters per hectare per year (sufficient to cover soil to a depth of from 50 to 100 ft.). The amount diverted by the canals amounts usually to 100 liters per second per hectare" (1.43 cu. ft. per second per acre).—In commenting upon this apparently exorbitant use of water, the author says:

"Nobody has been able up to the present to stop this harmful practice, for the farmer does not consider it prejudicial to the maintenance of soil fertility, the general idea being that 'too much water can not be used,' yet by following these methods the soluble constituents of the soil disappear, the humus becomes less and less capable of nitrification, the free phosphoric acid is unable to combine with bases and is slowly drained away, lime is dissolved in the presence of the excess of carbonic acid and is likewise lost through drainage."

A sand trap for irrigating ditches, H. O. CRAFTS (*Engin. Rec., 54 (1906), No. 6, pp. 150, 151*).—Some considerations bearing on the necessity of such devices in the case of canals diverting water from streams carrying large amounts of foreign matter, and a description of a typical sand trap.

The underflow in Arkansas Valley in western Kansas, C. S. SLICHTER (*U. S. Geol. Survey, Water-Supply and Irrig. Paper No. 153, pp. 90, pls. 3, figs. 24*).—Investigations on the underflow of the Arkansas River were made during the summer of 1904. The following principal conclusions were reached:

"(1) The underflow of Arkansas River moves at an average rate of 8 ft. per 24 hours, in the general direction of the valley.

"(2) The water plane slopes to the east at the rate of $7\frac{1}{2}$ ft. per mile and toward the river at the rate of 2 to 3 ft. per mile.

"(5) The underflow has its origin in the rainfall on the sand hills south of the river and on the bottom lands and plains north of the river.

"(7) The influence of the floods in the river upon the ground-water level does not extend $\frac{1}{2}$ mile north or south of channel.

"(8) A heavy rain contributes more to the underflow than a flood.

"(9) On the sandy bottom 60 per cent of an ordinary rain reaches the water plane as a permanent contribution.

"(10) The amount of dissolved salts grows less with the depth and with distance from the river channel.

"(11) There is no appreciable run-off in vicinity of Garden, Kans.

"(12) Carefully constructed wells in Arkansas Valley are capable of yielding very large amounts of water. Each square foot of percolating surface of well strainers can be relied upon to yield more than 0.25 gal. of water per minute under 1-ft. head.

"(14) Private pumping plants in the bottom lands will be profitable for irrigation if proper kind of power be used. . . . The present cost of pumping with gasoline for fuel is not encouraging."

The measurements of movement of underflow were made by the electrical method. Ground-water levels were obtained by observing water levels in private and specially sunk wells. Various contour maps of the water plane, cross-sections at various points, and views of cardboard models of changes in water plane at different localities illustrate the report.

Underground water in the valleys of Utah Lake and Jordan River, Utah, G. B. RICHARDSON (*U. S. Geol. Survey, Water-Supply and Irrig. Paper No. 157, pp. 81, pls. 9, figs. 5*).—This paper "outlines conditions of occurrence of the subterranean waters and describes their development in the valleys of Utah Lake and Jordan River."

Water powers of northern Wisconsin, L. S. SMITH (*U. S. Geol. Survey, Water-Supply and Irrig. Paper No. 156, pp. 145, pls. 5, figs. 5*).—A study of the water powers of the various drainage systems of northern Wisconsin, including for each system information as to its topography and drainage, reservoir sites, and the water powers developed along the different streams.

High-lift turbine pumps; their design and efficiency, R. J. DURLEY (*Engin. Mag., 31 (1906), No. 4, pp. 503-525, figs. 24*).—A review of the work which has been done in the last few years in the application of the centrifugal pump to those high-lift operations where formerly only the reciprocating pump was practicable.

These high-lift centrifugal pumps differ from the usual centrifugal pumps merely in having a ring of guide blades surrounding the impeller. By placing turbine pumps in series so that the first impeller discharges into a space connected with the suction of the second wheel, and so on, a multiple-stage pump is obtained, making it possible to pump against correspondingly greater heads. The usual head for a multiple-stage pump is from 300 to 600 ft., though by putting two or more such pumps in series heads up to 1,500 ft. have been attained.

"The results attained by the modern high-lift centrifugal pump may be stated generally as follows: An efficiency in most cases of 70 to 75 per cent can be obtained, and under suitable conditions, when the relation between head and discharge is most favorable, this may even reach 80 per cent on trial.

"It is probable that further progress will soon enable efficiencies corresponding to those of the best water turbines to be obtained.

"It is worthy of remark that high-lift turbine pumps can maintain their original efficiency much better than is usual with large piston pumps."

A number of examples are cited of successful application of the turbine pump to various purposes, and the article is illustrated by numerous diagrams and half-tones of different types of pumps.

Suction gas producer trials (*Engineer [London], 101 (1906), No. 2635, pp. 659, 660, figs. 10*).—The 20-horsepower plant of the National Gas Company, Ltd., Ashton-under-Lyne, secured the gold medal in the tests conducted under the auspices of the Royal Agricultural Society at Derby.

The main features of this plant consist of a vaporizer surrounding the upper portion of the generator, which can be removed for periodic cleaning when using hard water; and of a device for heating the air previous to its mixture with the steam. The latter device consists of a spiral passageway located in the outlet of the generator. The walls of the passage are highly heated by the outflowing gas, and the air in traversing the passage becomes correspondingly hot, enabling it to carry along the requisite quantity of steam in suspension as it enters the generator. A hand-operated fan is also provided to facilitate starting. The gases are cleaned and cooled by being passed through an ordinary coke scrubber, after which they pass directly to the engine.

Test of producer gas engine plant at Toledo, Ohio (*Gas Engine*, 8 (1906), No. 8, pp. 254-256).—Report of a test of gas engine and producer plant of American design and manufacture. On test the fuel consumption was 0.84 lb. of Pennsylvania pea anthracite coal per brake-horsepower hour, thus giving a thermal efficiency of about 24 per cent. The same plant now in commercial operation uses 1.14 lbs. of coal per brake-horsepower per hour. The efficiency of the producer alone was found to be about 93 per cent.

The use of alcohol as a fuel for gas engines, II. DIEDERICKS (*Internat. Mar. Engin.*, 1906, pp. 263-270).—In this article the author gives a very complete résumé of the whole subject, his information being drawn largely from German practice. He considers the fuel value and physical properties of alcohol, and the details of the alcohol engine wherever they may be different from a gasoline or crude-oil engine.

In the discussion of denaturizing agents for ethyl alcohol the following table is given, showing the materials and their percentages as used in different countries:

Denaturizing agents used in different countries.

Country.	Specific gravity of denaturized alcohol at 15° C.	Methylene (wood alcohol) and its impurities.	Pyridine or pyridine bases.	Acetone.	Benzol.	Benzine.
		<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
France.....	0.832	7.5	2.5	0.5
Germany:						
Denaturized alcohol.....	.819	1.5	0.5	.5
Motor alcohol.....	.825	.75	.25	.25	2.0
Austria:						
Denaturized alcohol.....	.835	3.75	.5	1.25
Motor alcohol.....	.826	.5	Trace.	Trace.	2.5
Russia.....	.836	10.0	.5	5.0
Italy—Motor alcohol.....	.835	6.5	.65	2.0	1.0
Switzerland.....	.837	5.0	.32	2.2

With regard to benzol the author states that "from 10 to 40 per cent is sometimes employed, thus raising the heating value of the fuel and thus decreasing the cost per heat unit." As to the rusting of the engine cylinder by the use of alcohol, it is claimed that this may be obviated by greater care in securing a proper mixture of air and alcohol and by using benzol as an additional safeguard. Several types of alcohol carbureters are illustrated and described, and attention is called to the fact that a high degree of heating in the carbureter is undesirable from the standpoint of capacity and because of danger of pre-ignition. The best temperature for the carbureter is shown to be between 75 and 80° F.

In discussing the efficiency and cost of operation of engines using different explosive fuels, the author brings out certain facts not generally recognized.

Assuming that alcohol can be put on the market at the same price as gasoline, he is able to compute the heat cost, as shown in the following table:

Relative heat cost of alcohol, gasoline, and kerosene.

Fuel.	Heating value per pound	Cost per—		Specific gravity.	Cost of 10,000 B. T. U.
		Gallon.	Pound.		
		<i>B. T. U.</i>	<i>Cents.</i>		
Gasoline.....	19,000	15.0	2.57	0.710	1.35
Kerosene.....	18,500	13.0	1.88	.800	1.02
Alcohol, 90 per cent.....	10,080	15.0	2.21	.815	2.19

From German tests the following table of economy and cost figures is collated:

Relative economy of alcohol, etc. (German data).

Fuel.	Cost for 10,000 B. T. U.	Best consumption of fuel per B. H. P. hour.	Best thermal brake efficiency.	B. T. U. per B. H. P. hour.	Fuel cost per B. H. P. hour.
	<i>Cents.</i>	<i>Pound.</i>	<i>Per cent.</i>		<i>Cents.</i>
Gasoline.....	1.35	0.580	23.0	11,000	1.485
Kerosene.....	1.02	.725	18.0	14,140	1.442
Alcohol, 90 per cent.....	2.19	.803	31.7	8,030	1.758

From these figures the author concludes that at the present time, with 90 per cent alcohol at 15 cts., the operation with alcohol would cost about 19 per cent more than with gasoline and about 22 per cent more than with kerosene. The advantage of gasoline from the standpoint of fuel cost is, however, said to be less than the other advantages in favor of the alcohol engine, which accounts for its extended application in European countries.

Free alcohol in the arts and as fuel, C. BASKERVILLE (*Amer. Mo. Rev. of Reviews*, 34 (1906), No. 199, pp. 211-214).—A brief discussion of the uses of alcohol, its manufacture and denaturization, with certain economic and social conditions likely to result from the removal of the tax upon the denaturized product.

The alcohol law and its relation to American industry, D. A. WILLEY (*Tradesman*, 55 (1906), No. 9, p. 51).—The writer reviews the status of the alcohol industry in France and Germany and makes some predictions as to its future in this country under the "alcohol law."

It is held that alcohol can be distilled from corn at a total expense of less than 12 cts. per gallon, and from refuse of molasses, beets, and sugar cane at about 10 cts. per gallon. As an instance of the industrial development which will result from the use of grain alcohol, the author mentions one large implement firm which has enlarged its plant purposely for making gas engines so that it will be able to build no less than 20,000 a year. "The indications are that fuel stations for distributing alcohol will be located throughout the United States, just as petroleum tanks are now situated." The writer thinks "the advantages to the South and West from the use of alcohol are especially notable, since these sections produce such an enormous quantity of corn, potatoes, and beets, together with refuse molasses from sugar manufacture."

Firing boilers with vegetable fuels, M. RINGELMANN (*Jour. Agr. Prat.*, n. ser., 12 (1906), No. 28, pp. 46-50).—In this article means are described for utilizing as a fuel peat, wood, tree branches, bark, sawdust, dry weeds, straw, sugar-cane stalks, etc. The quantities of each necessary per horsepower hour are given, and special types of furnaces adapted for such fuels are illustrated and described.

Science in thrashing, C. F. CONNER (*St. Joseph, Mich.: The Threshermen's Review Co., 1906, pp. 174, figs. 20*).—In this work the author treats of the operation, management, and care of thrashing machinery. In the first portion of the book the various parts of the thrasher are described and their functions explained. Numerous practical suggestions as to adjustments and management are given.

In part 2 traction and portable engines are considered, some thermodynamic theory being included, together with explanations of the action and advice as to the care of various engine and boiler appliances.

Refrigerating apparatus, H. PILLAUD (*Rev. Hort. [Paris], 78 (1906), No. 15, pp. 355-358*).—In this article is noted the increasing application of cold storage for the preservation of fruits and vegetables as well as bulbs and flowers. Various machines exhibited at the last agricultural show at Paris are described. Some of these machines are intended for hand power, the capacity being about 1,300 gm. of ice per hour. The various refrigerating mediums used in the machines exhibited were ammonia, carbonic acid, sulphur dioxide, and methylated chlorine.

RURAL ECONOMICS.

How to choose a farm, T. F. HUNT (*New York: The Macmillan Co., 1906, pp. XVIII+412, figs. 133*).—"In this book the attempt has been made to state the principles concerned in the selection of a farm, and then to apply these principles to a discussion of the different regions of the Western Continent."

The author regards farming as a business, and treats the selection, arrangement, and management of a farm from the standpoint of making a profit. To this end fertility of soil, topography, nearness of location to market, and transportation facilities for the products of the farm are important factors in selecting farm property. "The local market is often of considerable advantage for the sale of the minor products of the farm, even when the major products are shipped to a distant market."

The United States is divided by the author into geographical divisions which practically conform in nature of soil, climate, and suitability of crops. Methods of cultivation adapted to each region are given, as well as plans and illustrations of typical farms in these different sections, in the outlying possessions of the United States, and in other countries in North and South America.

An appendix contains information about securing title to public lands in the United States and Canada, various agricultural statistics, and an extended bibliography.

The marketing of Irish produce (*Dept. Agr. and Tech. Instr. Ireland Jour., 6 (1906), No. 4, pp. 662-675*).—Based upon information secured from a large number of wholesale buyers of Irish agricultural produce, attention is called to the defects in present methods of grading and packing eggs, crammed poultry, and fruits. Suggestions are made to Irish producers and shippers for improving present methods of marketing these and similar goods with a view to more successfully meeting foreign competition in London and other British markets.

The economic future of the negro—the factor of white competition, W. E. B. DUBOIS and A. H. STONE (*Pubs. Amer. Econ. Assoc., 3, ser., 7 (1906), No. 1, pp. 219-294*).—This is the subject of 2 papers read at the eighteenth annual meeting of the American Economic Association held at Baltimore, Md., December 27-29, 1905.

Statistics are given which show that white farm laborers and particularly Italian immigrants are slowly displacing the colored race in the South along the line of agricultural pursuits. It is believed, nevertheless, that "the home of the masses of the [colored] race must remain in the Southern States, and that their destiny must be worked out upon the soil." Better educational and agri-

cultural systems, the privilege of acquiring land, justice in executing wage and land tenure contracts, cultivation of food supplies in addition to cotton, and intensive culture are urged as means of raising the million and a half of colored farmers and farm laborers to a position of economic equality with their white competitors.

The packers, the private car lines, and the people, J. O. ARMOUR (*Philadelphia: Henry Altemus Co., 1906, pp. XIV + 15-380*).—The author treats of the origin and development of the refrigerator-car service, and gives statistics to show to what extent this means of transportation has been instrumental in developing the cattle, fruit, vegetable, and other rural industries throughout the United States. The advantages of this service in supplying fresh agricultural products at all seasons of the year and at reasonable prices to distant urban populations are also indicated.

Yearbook of world economics, R. CALWER (*Jahrbuch der Weltwirtschaft, Jena: Gustav Fischer, 1906, pp. VI + 281*).—In this publication statistical data relating to labor, agriculture, mining, iron and textile manufactures, finance, etc., for the year 1904, in comparison with preceding years, are reported.

The chapter on agriculture is mainly devoted to the world's production of wheat, rye, barley, oats, and corn. The acreage devoted to the growth of these crops in the main cereal-growing countries is indicated, together with the prices per ton in the principal markets of the world. Statistics are given which show that there was a gradual increase in cereal yield from 1878 to 1904.

Foreign live stock and dead meat imports into the United Kingdom (*Dept. Agr. and Tech. Instr. Ireland Jour., 6 (1906), No. 4, pp. 700-708, dms. 7*).—Comparative statistics of the imports of live stock and meats into Great Britain from Ireland and foreign and colonial countries for the years 1885 to 1905, inclusive, are reported and discussed.

The highest total value of live stock imported from foreign and colonial countries was recorded in 1897, amounting to £11,380,492. Since then the live stock import trade has slowly declined, particularly with pigs and sheep. The import of live cattle from foreign countries, however, has not changed much from year to year. In 1905 the returns show the number of cattle imported from foreign countries to be 565,139, valued at £9,665,806, as compared with 749,131 imported from Ireland.

As regards the importation of fresh meat into the United Kingdom, there has been a steady increase of value from £4,016,684 in 1885 to £17,430,443 in 1905. Nine-tenths of the fresh beef imported comes from the United States and Argentina, but the latter is slowly taking the lead in this branch of British trade as shown by the following figures:

Imports of fresh beef into the United Kingdom.

Imported from the—	In 1904.	In 1905.	In 1906 (six months).
	<i>Cwt.</i>	<i>Cwt.</i>	<i>Cwt.</i>
United States.....	2,395,836	2,232,206	1,228,743
Argentina.....	1,675,271	2,580,152	1,517,103

"The prices realized, however, by Argentine beef remain considerably lower than those obtained by the fresh beef from the United States," while home-grown and Irish prime beef maintains a clear lead over all in market prices.

The attention of the Irish farmer is called to the fact that the imports of foreign and colonial meat have been increasing more rapidly than any other agricultural import which competes with home produce. This, it is claimed, "points to the fact that Ireland must depend on a diversified agriculture and that she must produce fresh supplies of the best quality in every line."

Cotton: Its cultivation, marketing, manufacture, and the problems of the cotton world, C. W. BURKETT and C. H. POE (*New York: Doubleday, Page & Co., 1906, pp. XII + 331, pls. 58, figs. 4*).—A popular discussion of the subject of cotton, in all its economic aspects, from the preparation of the land to the final disposition of manufactured cotton fabrics. The authors point out the possibilities of the South to provide the world's chief markets not only with raw cotton, but with manufactured cotton goods and cotton-seed by-products. The value and importance of the cotton crop to the future agricultural and economic development of the South is especially emphasized.

MISCELLANEOUS.

Annual Report of Nevada Station, 1905 (*Nevada Sta. Rpt. 1905, pp. 45*).—This contains reports of the director and heads of departments. The director discusses reclamation and irrigation work in Nevada, farmers' institutes, etc., and gives a financial statement for the fiscal year ended June 30, 1905. The departmental reports contain notes on forage plants, orchard, and small fruits; spraying for the San José scale; meteorological conditions; experiments with field crops, etc.

Seventeenth Annual Report of South Carolina Station, 1904 (*South Carolina Sta. Rpt. 1904, pp. 26*).—This contains the organization list of the station, a financial statement for the fiscal year ended June 30, 1904, and reports of the vice-director and members of the station staff on the different lines of work during the year. The report of the chemist contains averages of analyses of different classes of fertilizers from 1891 to 1904.

Eighteenth Annual Report of Tennessee Station, 1905 (*Tennessee Sta. Rpt. 1905, pp. 47-63*).—This contains the organization list of the station, reports of the director and members of the station staff, and a financial statement for the fiscal year ended June 30, 1905. A preliminary note on clover diseases in Tennessee has been abstracted from another source (*E. S. R.*, 17, p. 567).

Experiment Station Work, XXXV (*U. S. Dept. Agr., Farmers' Bul. 259, pp. 32, figs. 3*).—This number contains articles on the following subjects: Use of commercial fertilizers, weight of lime per bushel, spreading lime, soil sterilization, weights per bushel of seeds, disease resistant crops, corn billbugs and root-lice, asparagus rust and its control, alfalfa meal as a feeding stuff, singed cacti as forage, cattle feeding in the South, milk fever, nail wounds in horses' feet, and use of a cheap canning outfit.

Press Bulletins Nos. 125-151 (*Kansas Sta. Bul. 136, pp. 143-206, fig. 1*).—Reprints of press bulletins on the following subjects: Meadow fescue, corn ensilage for steers, rabies or hydrophobia, preventive work against the Hessian fly, *Bromus inermis*, poison for prairie dogs and other rodents, warbles or grubs in cattle, the common garden mole, grasshopper poisons, baby beef, ringbone and spavin, contagious abortion in cattle, some troubles of swine, testing seed corn for vitality, garget (congestion of the udder), Kansas Experiment Station egg-laying contests, swine feeding test with sorghum-seed meal, Kafir-corn meal, soy-bean meal, and corn meal, summer pruning, preparing fruits for exhibition, the garden webworm, a shade-tree pest (the fall webworm), testing winter wheat varieties for western Kansas, a troublesome parasite of the horse, swine feeding tests (Armour's deodorized meat meal and alfalfa hay as supplementary feeds to corn), the San José scale in Kansas, and baby beef production with western feeds.

Bulletins of Alabama College Station (*Alabama College Sta. Index to Vol. XII, Buls. 127-129, and Ann. Rpt. 1904, pp. 105-112; Vol. XIII, Buls. 130-134, and Ann. Rpt. 1905, pp. 205-214*).

NOTES.

Alabama College Station.—C. S. Waldrop has been appointed assistant chemist.

Arkansas University and Station.—Hon. C. C. Hamby, of Prescott, has been appointed a member of the board of trustees of the university, to succeed Hon. Dougald McMillan, resigned. The work of tick eradication in the northern part of the State has been begun by a preliminary survey of Benton and Washington counties. Dr. W. Lenton, recently appointed instructor in veterinary science and veterinarian to the station, will have charge of the work, in cooperation with the Bureau of Animal Industry of this Department. C. H. Tourgee, whose resignation from the Oklahoma College and Station was previously noted, has been appointed in the dairy department of the Arkansas Station.

Colorado College and Station.—H. M. Cottrell, formerly of the Kansas College and Station, has been appointed professor of animal husbandry, vice J. A. McLean, who, as previously noted, has gone to the Iowa College. L. F. Paull, formerly of the Kansas Station and for the last year a graduate student at Cornell University, has, according to *Cornell Countryman*, been appointed assistant horticulturist at the Colorado Station.

Georgia Station.—At a recent meeting of the governing board, the resignation of R. J. Redding as director was accepted, and Martin V. Calvin, of Augusta, Ga., secretary of the State Agricultural Society, was elected to succeed him. J. M. Kimbrough, agriculturist, was elected vice-director.

Illinois Station.—A. N. Gregory and N. E. Bell, graduates in chemistry of the North Carolina College, have been appointed as analytical chemists to succeed W. F. Pate, who, as previously noted, has gone to the Ohio Station, and C. E. Leighty, who has accepted a position with the Bureau of Plant Industry of this Department. W. G. Eckhardt has been appointed assistant in soil fertility.

Kansas College and Station.—The new horticultural building is nearing completion. The greenhouses are to be replaced by a large modern structure this winter. The station has leased 40 acres of farm land just outside the city for experiments in dry farming.

Kentucky Station.—E. S. Good, formerly connected with the Illinois University and Station, has accepted a position in animal husbandry at the station.

Louisiana Stations.—E. Rosenthal, dairyman at the Calhoun Station, has resigned.

Massachusetts College and Station.—The formal inauguration of Kenyon L. Butterfield as president of the college took place October 17. Among the institutions represented at the exercises were the agricultural colleges of Connecticut, Michigan and Rhode Island, Boston, Clark and Maine universities, Amherst, Mt. Holyoke, Simmons and Smith colleges, the Case School of Applied Science, and the Massachusetts Institute of Technology. In an introductory address M. F. Dickinson, for the board of trustees, paid a glowing tribute to the late President Goodell. The subject of the inaugural address of President Butterfield was The Forward Movement in Agricultural Education. In this he outlined the directions along which progress is making, the special mission

and opportunities of the college, and a program for strengthening its work and developing its field of usefulness. H. A. Parsons has been appointed dairy tester, vice J. G. Cook, resigned. F. G. Hellyar, inspector in the division of foods and feeding, has resigned to accept a position as assistant in the agricultural department at Mount Hermon School.

Michigan College.—A department of farm mechanics has been established and placed under the direction of L. J. Smith, a graduate of the engineering course at this college in 1906.

Missouri University and Station.—Among the recent appointments are the following: Miss Edna D. Day, Ph. D., of the University of Chicago, as assistant professor of household economics; L. F. Childers, of the University of Missouri, as assistant in agronomy; E. A. Trowbridge, as assistant in animal husbandry, and W. H. Chandler, of the University of Missouri, as assistant in horticulture. H. S. Wayman has been promoted from assistant in dairy husbandry to instructor in the same subject. B. M. Duggar, botanist, and W. L. Howard, assistant horticulturist, have returned from a year's leave of absence in Europe.

Nebraska University and Station.—Roscoe H. Shaw, assistant professor of agricultural chemistry in the university and associate chemist in the station, has resigned to become assistant professor of dairy husbandry in the University of Missouri. He is also connected with the Dairy Division of this Department as dairy expert.

Cornell University.—L. B. Judson, of the Idaho College and Station, has been appointed assistant professor of horticulture. The new buildings of the college of agriculture are approaching completion, and it is expected will be ready for occupancy this fall. A model schoolhouse is being erected as a part of the extension work. In addition to the usual recitation room, it will contain a large laboratory for nature study. An effort will be made to secure its duplication at many places in the State.

North Carolina College and Station.—J. G. Hall, who has been taking advanced work at Harvard University, has recently been added to the station staff as assistant pathologist. W. A. Syme, Ph. D., a graduate of the college and of Johns Hopkins University, has been appointed assistant chemist in the station and instructor in the college, and J. C. Temple has been appointed assistant in bacteriological work in the college and station. He will give his attention especially to work in connection with soils. Robert S. Curtis, a graduate of the Iowa Agricultural College, has become assistant in animal husbandry in the college and station.

Porto Rico Station.—D. W. May, director of the station, has returned for a short visit, and will attend the convention of the Association of American Agricultural Colleges and Experiment Stations at Baton Rouge. Pineapple plants sent up from the station last spring and planted outdoors at the Arlington Farm of this Department produced fruit which was of good flavor and well matured by the first of October.

South Dakota Station.—The station plans to erect a building to be used by the veterinarian in investigating diseases of farm animals, at a cost of about \$2,000.

West Virginia University and Station.—T. C. Johnson has been placed in charge of the botanical work of the university and is no longer connected with the station. E. B. Copeland, who has been connected with the government laboratories at Manila, has been elected horticulturist of the station and will enter on his work about the middle of November. He is a graduate of Leland Stanford University, and previous to going to Manila occupied the chair of botany in this university.

Wisconsin University and Station.—Andrew McLeod has been appointed instructor in soils in the university and assistant in soils in the station. Conrad Hoffmann has become assistant in agriculture and bacteriology and Christ

Schroeder assistant in animal husbandry in the university and station, and E. J. Delwiche superintendent of the Northern Wisconsin substations.

State Experimental Farm in Brazil.—The following facts concerning the Fazenda Modelo, at Piracicaba, Brazil, are furnished by its director, J. William Hart, formerly of the University of Illinois:

The Fazenda has an area of 319.12 hectares (about 788 acres). About 50 hectares are under cultivation, and the remainder is pasture and second-growth timber. The principal crops are corn, rice, beans, sugar cane, and cotton. Many variety tests are carried on. One field of corn from selected seed yielded at the rate of 60 bu. per acre. Florida velvet beans, planted in corn at the last cultivation, grew vigorously, and the roots were found to be covered with nodules. Plat tests with alfalfa and California burr clover indicate no advantage from liming, and that phosphoric acid is most needed. Alfalfa grown under irrigation has given good yields, and garden vegetables are being grown in contour checks and depressed beds. If this proves practicable a profitable field will be opened, as during the dry season from June to November the markets are almost bare of green vegetables. It is also hoped that by means of irrigation the planting of rice may be deferred so that the crop will mature two months later than at present. In this way dry, sunny weather will be insured for harvesting and thrashing.

A plantation of 9,000 coffee trees and a vineyard of 400 grapevines have been planted on newly cleared land. Over 100,000 seedling oranges and lemons are in nursery rows, ready to be budded. George Weigt, a graduate of the Royal Gardens, Kew, England, is horticulturist and pomologist.

The students of the Louis Queiros School of Agriculture receive instruction in modern agricultural methods. At present 47 are in attendance. The Fazenda is equipped with the latest and best American machinery. The cattle and hogs are mostly native blood, but improvement is being sought through importations from Europe.

The State of São Paulo appropriates about \$25,000 a year for the maintenance of the Fazenda, besides special appropriations for the erection of buildings.

New Experiment Stations in Madras.—The Madras Department of Agriculture has arranged to start a new experiment station at Attur, in the Chingleput district, and another at Nandyal, in the Kurnool district. The former will be devoted to the thorough trial of perennial and exotic cottons under irrigation and to the growth of fodder crops, and the latter is to be devoted mainly to the study of the varieties of cotton known as "Northerns" and their improvement by selection and crossbreeding. A study of the sorghum crop of the Nandyal Valley will also be made.

Chinese Experimental Field.—The Chinese Government has approved a request made by the native board of commerce at Peking for the use of the Loshan garden, which is situated on the Imperial Road outside of the Hsieh Gate of Peking, with an area of 166 $\frac{2}{3}$ acres, as a field for agricultural experiments. In 1905 the board was authorized to take measures for the encouragement of agriculture, but up to the present, with the exception of the few experimental fields and agricultural schools established in Chihli, Shantung, Shansi, Honan, and Fukien, little has been done along this line.

Agricultural Investigation for Tropical Agriculture.—At the York meeting of the British Association the past summer Prof. Wyndham Dunstan, in his opening address to the section of chemistry, speaking of some of the opportunities afforded to applied chemistry in the field of agriculture, said:

"If we are to compete successfully with foreign countries, it is necessary that the position of science in relation to tropical agriculture should be definitely

recognized. The days when a botanical garden served the purpose of an entire scientific establishment in a colony have passed away, and we now require, in order that a proper return should be obtained and the natives assisted in their agricultural practice, a scientific department with a proper complement of specially trained officers, including a consulting chemist, other specialists being added to the staff as the requirements arise. These officers should be remunerated on a scale likely to attract some of the best educated men from this country, which is at present far from being the case."

Macdonald College.—Sir William Macdonald, who established the institution at St. Anne de Bellevue, has deeded the property to McGill University and provided an endowment of \$2,000,000, besides the plant. A main building, buildings for agriculture and horticulture, for chemistry and physics, for biology and bacteriology, are in process of construction, together with a boys' and a girls' building, a horticultural barn, and a power house.

All of the buildings are substantially built of brick, iron, and concrete, with partitions of fireproof hollow tile and floors of concrete with wood laid on top in certain of the rooms. The walls are lined inside with hollow tiles, so as to give a dead air space. The construction is very thorough in every respect. The buildings are to be heated from a central heating plant, with a comprehensive ventilating system. Several of them are connected by underground passages, to be used in bad weather. It is expected that the buildings will be ready for occupancy in the fall of 1907. They will provide accommodations for about 400 pupils—175 men and 225 women. The school has a farm of about 560 acres, a part of which is in cultivation. One of the farms purchased was provided with large barns for cattle, and considerable stock is being kept there. The college will have a large poultry plant and extensive rooms for showing agricultural machinery.

In addition to training boys and girls for farm life, a regular normal department will be conducted for the training of teachers, with a special view to providing persons suited to teaching elementary agriculture, nature study, and the like. Although affiliated with McGill University, the faculty of the college will dictate as to the courses except such as lead to degrees.

Elementary Agricultural Education.—The Morgan Township High School, located at Okeana, Butler County, Ohio, has introduced elementary agriculture, and a class of 9 students is taking the work this year. There is also in the school an agricultural club, organized under the direction of the Ohio State University.

The committee on education of the Ohio State Grange has undertaken an active campaign for the study of agriculture and domestic science in the subordinate granges of the State, under the direction of the college of agriculture and domestic science of the Ohio State University. The committee having this work in charge has issued a number of educational circulars and two bulletins, one setting forth the objects of the work and giving an outline of a course of study and reading on the soil and its management, and the other an outline and course of study on farm crops and gardening.

The college of agriculture of Illinois University has added an instructor this year for the purpose of preparing prospective teachers of agriculture and to determine what phases of agriculture seem best adapted for introduction into public schools. A small class of college students has taken up this work.

The County Superintendents' Association of Indiana has forwarded to Purdue University a formal request to organize a training school for teachers in agriculture and nature study.

The *Oklahoma School Herald* is running a department of agriculture, edited by E. E. Balcomb, teacher of agriculture in the Southwestern Normal School.

Agricultural Instruction in Ireland.—According to the Annual Report of the Department of Agriculture and Technical Instruction for Ireland, 1904-5, agricultural instruction was continued at the Royal College of Science, Dublin, the Albert Agricultural College, Glasnevin, and at Munster Institute, Cork. At the Royal College of Science 38 students were in attendance, at the Albert Agricultural College 68, and at Munster Institute 50, the latter all young women. The courses in dairying, calf rearing, poultry keeping, gardening, sewing, cooking, and laundry work at the Munster Institute are so highly appreciated that although only 50 students can be admitted, there were at the time of this report nearly 250 applicants on the waiting list of the department.

Winter agricultural schools, running from six to twenty-six weeks, were held at 16 centers and 317 students were enrolled. Twenty itinerant instructors were at work during the year and attended a total of 1,054 meetings of farmers. A large number would have been employed but for the difficulty of securing men of adequate training and experience. To overcome this difficulty somewhat the department held a forestry school for instructors in agriculture at Avondale Forestry Station, a poultry-fattening school at Avondale Poultry Station, and a bee-keeping school at Albert Agricultural College.

Reclamation of the Rann of Cutch in India.—The following concerning this great reclamation enterprise is quoted from *Science*: "According to Reuter's Agency, the Indian government has under consideration a scheme for reclaiming the Rann of Cutch, a work which, if carried out, will be similar to that undertaken by the Dutch in the Zuider Zee. The Rann of Cutch is a waste, at some seasons water, at others land, and it is proposed to reclaim it by closing the inlets from the sea, which are narrow. The water, which is everywhere shallow, would then evaporate rapidly, leaving heavy saline deposits. These, it is thought, could be washed out and drained away by a great canal to be constructed from the Indus. The application of scientific agriculture to the reclaimed land and the construction of a railway linking Karachi and Bombay would complete the proposed scheme."

International Conference on Hybridization and Plant Breeding.—At the concluding meeting of this conference, according to a note in *Nature*, Veitch gold memorial medals were presented to W. Bateson, F. R. S., the president of the conference, Professor Johannsen, Professor Wittmack, and Prof. Maurice de Vilmorin, and silver-gilt Banksian medals to Miss E. R. Saunders, lecturer on botany at Newnham College, and R. H. Biffen, for eminent services rendered to scientific and practical horticulture. Professor de Vilmorin, as the representative of the Horticultural Society and the Botanical Society of France, invited the society to hold its next conference at Paris.

During the conference the following resolution was adopted: "That the members of the International Conference on Hybridization and Plant Breeding, gathered from all parts of the world and assembled in the Hall of the Royal Horticultural Society of Great Britain, desire to express to the President of the United States of America and to the Minister of the Department of Agriculture at Washington their hearty appreciation of and thanks for the invaluable assistance which has been given to farmers, horticulturists, planters, and scientific men throughout the whole world by the liberal distribution of American research publications."

Jubilee Horticultural Exposition.—An international art and horticultural exposition is to be held at Mannheim, Germany, during the growing season of 1907. Eight special exhibits are to be made on different dates, six of which will be international in character. The first of the international exhibits will be held May 18-21, at which forced fruits and vegetables, including asparagus, will be the special features. A second exhibit will be held June 8-11, with straw-

berries, early cherries, stone fruits, and early vegetables as the leading features. A special cherry exhibit on June 22-25 will be confined to German productions. On July 13-15 an international exhibit of early fruits and vegetables will be made, on August 10-12 of early pome and drupaceous fruits, on September 21-24 of fall vegetables, and on October 5-14 a general exhibit of fruits.

An Abstract Journal for Tuberculosis.—The literature relating to tuberculosis of man and animals has become so extensive and is published in such a great variety of journals, some of which are mainly devoted to other matters than medicine, that it is almost impossible to obtain abstracts even of the most important articles without consulting a long list of journals. To supply this apparent bibliographical deficiency a new abstract journal has been established, *Internationales Centralblatt für die gesammte Tuberkulose-Literatur*, the object of which is to contain as complete a list of references as possible to the literature in the whole field of tuberculosis.

Miscellaneous.—It is learned from *Nature* that Maj. P. G. Craigie, assistant secretary of the British Board of Agriculture and Fisheries, and known to many through his visit to the American stations, has retired. He is succeeded by Mr. Henry Rew.

Dr. Otto Müller, of Königsberg, has been appointed director of the Bacteriological Institute of the East Prussian Chamber of Agriculture, which opened October 1, 1906.

The American Breeders' Association will hold its regular winter meeting at Columbus, Ohio, January 15-18, 1907. The sessions will be held at the university and board of trade buildings. The association now has an annual membership of over 950, with 42 life members. Its second annual report has just been issued.

A New England conference on rural progress is to be held in Boston next March, under the auspices of the Massachusetts State Board of Agriculture.

A farmers' reading course in practical agriculture for the farmers of South Africa is to be given under the supervision of William P. Brooks, director of the Massachusetts Station. The course will be covered in Brooks' Agriculture, Vols. I and II, and the student will be guided in his studies by a large syllabus of over 60 pages, containing lesson assignments, helpful suggestions, directions for experiments, and over 2,000 questions on the lessons.

At the opening of the session of the Southeastern Agricultural College at Wye, October 1, Dr. Henry E. Armstrong delivered the inaugural address. A conference of fruit growers was held at the college October 22, with discussions upon methods of planting, fungus diseases, insect attacks, and strawberry culture, by S. C. Pickering, E. C. Salmon, F. V. Theobald, and W. P. Wright. Registration for the conference was in advance.

The Queensland Department of Agriculture has inaugurated a system whereby young men who find it impractical to attend the Agricultural College at Gatton are given the opportunity of gaining an insight into farming at the Hermitage State Farm, Warwick.

The department of agriculture of India has begun the publication of a series of memoirs, which deal with scientific subjects relating to agriculture. These memoirs will be published in separate series, designated as Chemical Series, Botanical Series, Entomological Series, etc., and will appear as material is available for publication. Up to July, 1906, three numbers had appeared in the Botanical Series—The Haustoria of the Sandalwood, Indian Wheat Rusts, and Fungus Diseases of Sugar Cane in Bengal. In the Chemical Series, one number has been issued on the composition of Indian Rain and Dew, and in the Entomological Series one number, The Bombay Locust.

Compilation of analyses of agricultural chemicals, etc., Haskins	220
Official inspection of commercial fertilizers, 1905, Goessmann	220
Report on general work in the chemical laboratory, Goessmann	220
Fertilizer analyses, 1905-6, Kilgore	220
Analyses of commercial fertilizers	220
Inspection of commercial fertilizers, 1905, Woll and Olson	220

AGRICULTURAL BOTANY.

Report of the botanist, Stone and Monahan	221
The numbers of bacteria in sterilized and unsterilized soils, Osmun	222
Notes on formation of albuminoid substances in plants, Montemartini	222

	Page.
Stimulation of nutrition of plants, Micheels	222
Synthesis and breaking down of organic nitrogen in plants, Schulze	223
Formation and physiological use of pentosans in plants, Calabresi	223
Calcium salts and assimilation of nitrate nitrogen, Yermakov	223
Tubercles on legumes with and without cultures, Sheldon	223

FIELD CROPS.

Report on agricultural investigations in Alaska, 1905 [Field crops], Georgeson	224
Report on agricultural investigations in Hawaii, 1905 [Field crops], Smith	225
Report on agricultural investigations in Porto Rico, 1905 [Field crops], May	226
Report of the agriculturists, Brooks, Church, and Haskell	226
Influence of experiment-station work on culture of field crops, Schutel	227
Experiments with grain and forage plants, 1905, Moore and Stone	227
Wyoming forage plants and their chemical composition, Knight et al.	229
Forage crops grown at Coast Land Experiment Station, Garrison	229
Farm practice with forage crops in western Oregon and Washington, Hunter	229
Diversified farming in the cotton belt, Spillman et al	230
Summary of press bulletins	230
Business of seed and plant introduction and distribution, Pieters	230
Experiments on germination of new harvested seed, Eberhart	231
Effect of inbreeding in plants, Shamel	231
Breeding of cereals by means of artificial crossing, Tschermak	231
Feeding value of soiling crops at different stages of growth, von Feilitzen	232
Alfalfa as a forage crop of Pennsylvania, Watson	232
Inoculation experiments with alfalfa and soy beans, Russell and Moore	232
The improvement of corn in Pennsylvania, Wing	233
Eureka silage corn, its value for Massachusetts farmers, Lindsey and Smith	233
Variety and distance tests of corn and cotton, Kilgore et al	233
Cotton experiments, Newman	233
Cultivation of magney in the Philippine Islands, Edwards	234
Composition of soy beans, Frear	234
Experiments with sugar beets, season 1905, Woll, Moore, and Stone	234
Dark fire-cured tobacco of Virginia, McNess and Mathewson	235
The composition of turnips and swedes, Hendrick	235
Winter wheat, Wiancko and Fisher	235
The flinty condition of wheat, Ferle	236

HORTICULTURE.

[Horticultural investigations in Alaska], Georgeson	236
Report of the horticulturist, Henriksen	236
Report of the horticulturist, Waugh	236
Horticultural work	237
The book of market gardening, Castle	237
Excessive feeding as factor in producing variation in tomatoes, Sandsten	237
Rhubarb culture, Kunath	237
Rhubarb culture in England, Skalweit	237
New fruit productions of the Department of Agriculture, Webber	237
Promising new fruits, Taylor	238
Relation of early maturity to hardiness in trees, Emerson	238
Conditions which affect time of annual flowering of fruit trees, Sandsten	238
New opportunities in subtropical fruit growing, Rolfs	239
The handling of fruit for transportation, Powell	239
Small fruits in 1904, Pillsbury	239
Cranberry investigations, Whitson, Haskins, and Malde	239
Tannic acid as a fertilizer for grapes, Cavazza	240
Report of the coffee specialist, Van Leenhoff	240
Cross pollination of almonds, Dargitz	240
Progress in drug-plant cultivation, Trne	241
Hybrids and hybridization among bulbous plants, Van Tubergen	241
Compilation of analyses of fruits, garden crops, and insecticides, Haskins	241

EXPERIMENT STATION RECORD.

VOL. XVIII.

NOVEMBER, 1906.

No. 3.

The dedication of the new buildings for the Harvard Medical School has attracted much attention, as marking in a high degree the development of instruction and research in medicine. Some of the addresses on that occasion might be applied with almost equal force to agriculture, and they are of broad interest as indicating advanced thought upon the relation of science to an important branch of practice.

President Eliot and Dr. W. H. Welch both laid great stress upon research as the fundamental basis for advancement in medicine and the importance of the laboratory as marking the highest stage of development to that end. They showed how medicine has progressed step by step with the development of science, and how the great epochs in its progress were attributable to new discoveries and deductions. "The great lesson taught by the history of this development of medicine through the centuries," Doctor Welch said, "has been the unconditional reverence for facts revealed by observation, experiment, and just inference, as contrasted with the sterility of mere speculation and reliance upon transmitted authority. The great epochs of this history have been characterized by some great discovery, by the introduction of some new method, or by the appearance of some man of genius to push investigation and scientific inference to limits not attainable by ordinary minds."

The development of laboratories was described as at once the cause and the result of such progress. "By teaching and exemplifying the only fruitful method of advancing natural knowledge laboratories have overthrown the dominance of authority and dogma and speculation;" and they have demonstrated that "the only abiding, living knowledge, powerful for right action, comes from intimate, personal contact with the objects of study." They have been one of the great factors in advancing research and have resulted in making our knowledge more exact. The laboratory method is now the accepted one in research in natural science.

Doctor Eliot pointed out the broad relations of investigation in various branches of science to the progress of medicine. "The most promising medical research of our day," he said, "makes use of bio-

logical, chemical, and physical science combined. Physiology advances by making applications of the principles, the methods, and the implements of all three sciences. . . . The world has observed, and will not forget, that some of the greatest contributors to the progress of medicine and surgery during the past thirty years have been not physicians, but naturalists and chemists. Pasteur was a chemist; Cohn, the teacher of Koch, a botanist, and Metchnikoff a zoologist. Students of disease must therefore be competent to utilize in their great task every aid which natural science can furnish. How vastly is the range of medical science and medical education broadened by this plain necessity! The dignity and serviceableness of the medical profession are heightened by every new demand on the intelligence and devotion of its members."

This thought was also voiced by Doctor Welch, who declared the subject-matter of medical study to be "complex and difficult far beyond that of any other natural or physical science." He advocated specialization as a great instrument of progress, for, although the various branches of medical science are interdependent, each has its own problems and methods, and "each is most fruitfully cultivated for its own sake by those specially trained for the work. . . . But the further division of labor is carried the more necessary does it become to emphasize essential unity of purpose and to secure coordination and cordial cooperation of allied sciences."

In the creative work of research and investigation the genius and ability of the man were placed above all else. Important as are the most ample and freely available facilities for productive research, "men count for more than stately edifice and all the pride and pomp of outward life. Research is not to be bought in the market place, nor does it follow the commercial law of supply and demand. The multitude can acquire knowledge; many there are who can impart it skillfully; smaller, but still considerable, is the number of those who can add new facts to the store of knowledge, but rare indeed are the thinkers, born with the genius for discovery and with the gift of the scientific imagination, to interpret in broad generalizations and laws the phenomena of nature. These last are the glory of a university. Search for them far and wide beyond college gate and city wall, and when found cherish them as a possession beyond all price."

The analogy between medicine and agriculture is not far to seek. This is especially the case when they are considered from the standpoint of their scientific development and their broad relationships. They have many points of similarity, and hence the lesson of the one may be applicable to the other.

The scientific aspects of both agriculture and medicine present very complex problems, those of the former quite as much as Doctor

Welch ascribed to medicine. Both rest upon the application of principles developed by various branches of science, and these principles and applications arranged and correlated form in each case a composite science. Thus complex relations and the necessity which they impose of utilizing the teachings of all natural science broaden agriculture and medicine alike and heighten the dignity of their practice.

The practice of agriculture, like that of medicine, depends upon the accumulation of experience and investigation and requires much judgment in the interpretation of observed results and their application. Until comparatively recent years the methods of practice were very largely dependent upon the accumulated observations and experiences of practical men. Hence the knowledge was largely empirical and was often without scientific foundation. The deductions upon which it was based were made without an understanding of the reason and causes of what was observed, and too broad generalizations and applications were made. These gradually became traditions of practice and had much the strength of scientific laws. A certain amount of mystery surrounded the practice of medicine, and this was also true of agriculture, especially the ability to produce certain results. Success was attributed largely to the skill of the individual, and it was intimated that the operations of neither were governed by the laws of science.

Gradually these ideas have been dispelled in the case of both medicine and agriculture, and this has come about in both cases as a result of progress in science and the development of methods of research. Progress in recent years has been rapid, and the application and reliability of the results in practice have become fully recognized. As a complex medical science has gradually been developed out of the teachings of investigations in chemistry, physics, and biology, which has prepared the way for intelligent practice in the prevention and combating of disease, so an equally complex science of agriculture is rapidly developing, which enables the art to break away from tradition and places it upon a more enlightened and intelligent basis.

The most noteworthy progress in medicine has come from fundamental investigation which disclosed the reason for observed results, taught the fundamental causes of disease, and has enabled the prevention as well as the intelligent treatment of the disease after it appeared. In agriculture, likewise, some of the most abiding and far-reaching results of research have come from that which was fundamental in the sense of broadening our definite knowledge of the relations and the intermediate steps between cause and effect, enabling the agriculturist to more largely control conditions instead of being at their mercy.

The same danger of reasoning and generalizing from empirical knowledge prevails to-day that did a century ago. The difference is one of degree rather than kind. While a wrong deduction at the present day would not become as fixed and deep-seated as formerly before the error would be detected, our agriculture is on so much more intensive and extensive scale that in the meantime more harm would have been done. The reason for investigation which will go beyond the economic result and extend our definite knowledge into many new lines which are now obscure was never more evident than at the present time. The need for it arises not only out of the necessities of the stations themselves in giving reliable and intelligent advice to the farmer, but from its importance to all agricultural teaching.

Agricultural instruction rests in a very large degree upon the facts which have been worked out by the experiment stations and similar agencies for investigation. Previous to their establishment the amount of material suited to agricultural instruction was small and was made up largely of empirical knowledge coupled with the experience of good farming. The work of the experiment stations has immensely broadened the fund of known facts and has laid a broad foundation for a science of agriculture. It has thus opened the way for placing agricultural teaching upon a better pedagogic basis.

This is the most important permanent result of our station work. Its broad influence and permanent value far outweigh the results which stop with the immediate answer to a practical question. As the progress of agricultural education in the past has been linked with agricultural investigation, so its higher development in the future will depend upon the development of agricultural science and the arrangement of the material in pedagogic form. In promoting this the experiment stations are keeping entirely within their legitimate province. They owe a duty to agricultural education which no other agency can discharge. In the highest sense they are institutions for education—education in the science as well as in the art.

In their annual reports for the past year President Hadley, of Yale, and President Jordan, of Leland Stanford, both have some interesting things to say upon the relations of instruction and investigation. Both emphasize the importance of research to the teacher and urge it as a logical and important phase of university work.

Doctor Jordan says: "To the university teacher individual research is the breath of life, and it is the duty of the institution in every reasonable way to foster its development. . . . No one can be a great teacher without the spirit of research; without this he lags behind the progress of knowledge, and his mental equipment becomes second hand." While in the case of most university men the practical purpose of research is that of making them better teachers, it

is held that a reasonable following of students is usually an aid to research and not a hindrance. Both presidents agree that the investigator and the results of his work are more fully realized when he couples with his investigation in a restricted way the work of the teacher.

President Hadley cautions against the danger of creating a separate or privileged class of research professors. "In some universities," he says, "there is a tendency to set some men apart for discovering new truth, while employing other men to teach old truth. This is a mistaken policy. We are not dealing with an ordinary case of division of labor. The chief argument for division of labor is that it makes each man more expert and more efficient in his own field of work. In university work, however, the man who tries to investigate distributed as widely as possible throughout the teach-who attempts to teach without investigating becomes a worse teacher instead of a better one. We want the opportunities for research and investigation distributed as widely as possible throughout the teaching force and the student body. We want to impress upon every man that teaching and discovery are both done at their best when done in combination."

But in making this statement President Hadley evidently refers to teaching in a broad sense, for he explains that "not every man should be compelled to lecture to classes, whether he is able to do so or not." There is a great deal of valuable teaching which is not done in the class room, or even in the laboratory. There are some men who teach best by their writings, their conversations, their intelligent suggestions for the work of others; but they should understand that they are part of the teaching force, and are simply doing their teaching in a different way from other men. Instead of setting such a man apart as a research professor, we should let him understand that withdrawal from the lecture room and relief from the duties of supervising elementary students carry with them a larger obligation to publish as fully as possible the results of all discoveries; to organize departments intelligently; to train up young men who can teach; and to make liberal room for such men, instead of trying to get in their way when their work becomes popular.

In this sense all our experiment station workers are teachers, and it is one of their most important functions. The Hatch Act itself requires it, and their teaching has not stopped with the bulletins and reports prepared in the line of regular duty.

A recent somewhat incomplete summary of their writings in permanent book form shows nearly 400 treatises, by 200 authors connected with the colleges and stations. These books cover practically the whole realm of agricultural science and practice, and draw largely upon the work of the stations. They indicate in a striking manner

the rapid progress which is being made in this country in building up a substantial body of agricultural literature, based upon the more definite and reliable information furnished by investigation.

The retirement of Director R. J. Redding, of the Georgia Station, will be learned with regret by his many friends and colleagues in experiment station work.

Director Redding is one of our oldest station officers in point of service, having come into the work when the station was moved from Athens to Griffin in 1890. The laying out of the fields and grounds at that place and the planning of its work devolved upon him; and the systematic conduct and careful attention to details which have characterized the work under him, as indeed all of the business of the station, reflect much credit upon his administration.

His career in the service of agriculture has been a long and honorable one, crowned with much practical usefulness, and he will lay down his work with the respect and esteem of all who have known him. The resolutions passed by the board of directors of the station in accepting his resignation evidence the appreciation of his services and the warm regard in which he is held.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY.

The detection of natural phosphates in phosphatic slags, L. LEDOUX (*Bul. Soc. Chim. Belg.*, 19 (1905), No. 8-9, pp. 265, 266).—The author proposes the following method, based upon the complete solubility of the phosphoric acid of pure slags in citric acid: Digest 3 gm. of the fine-ground material in 50 cc. of 40 per cent citric acid for one-half hour, shaking every 2 minutes; filter and treat the residue with 25 cc. of 40 per cent citric acid for one-half hour; filter and wash with hot water; dissolve the residue from the second treatment in nitric acid and test for phosphoric acid with ammonium nitro-molybdate. If the slag has not been adulterated with natural phosphate no reaction for phosphoric acid will be obtained.

The determination of the actual agricultural value of phosphatic slags, A. GRÉGOIRE (*Bul. Soc. Chim. Belg.*, 19 (1905), No. 8-9, p. 268).—Analyses of 25 samples of crude slag obtained directly from the works showed 4 to 12 per cent of phosphoric acid, 43 to 55 per cent of total lime, and 0.7 to 7.5 per cent of free lime. The silicic acid content was inversely proportional to that of lime. The solubility of the phosphoric acid in 2 per cent citric acid was 76 to 100 per cent. There was apparently no relation between free lime and the citric acid solubility of the phosphoric acid. The solubility of the phosphoric acid in ammonium citrate containing fluorids was 47 to 86 per cent.

A study of methods of determining phosphoric acid in phosphatic slag and natural phosphates, E. RUWET (*Bul. Agr. [Brussels]*, 22 (1906), No. 2, pp. 206-212; *abs. in Bul. Soc. Chim. Belg.*, 20 (1906), No. 7, pp. 244).—Comparative studies are reported from which the author concludes that the precipitates obtained in the Sonnenschein molybdic method contain $Mg_3(P'O_4)_2$, as well as $MgNH_4PO_4$, making the factor 0.8102 inapplicable, but that the precipitate obtained in the citro-mechanical method presents no such difficulties.

On methods of determination of phosphoric acid in artificial fertilizers, P. CHRISTENSEN (*Om Metoder til Bestemmelse af Fosforsyre i Kunstig Gødning. Copenhagen, 1905, pp. 195*).—A monograph on this subject which was awarded a prize offered by the Royal Danish Academy of Sciences.

A new modification of the method of determining phosphoric acid as magnesium-ammonium phosphate with especial reference to fertilizers, G. JÖRGENSEN (*Ztschr. Analyt. Chem.*, 45 (1906), No. 5-6, pp. 273-315; *abs. in Chem. Centbl.*, 1906, II, No. 4, pp. 359, 360).—The essential feature of the modification of his former method (E. S. R., 10, p. 934) which the author proposes consists of the precipitation of the ammonium-magnesium phosphate in a boiling solution.

Indirect determination of small amounts of magnesia by weighing the phosphoric acid of ammonium-magnesium-phosphate as phosphomolybdic anhydrid, G. BERJU (*Chem. Ztg.*, 30 (1906), No. 68, pp. 823-825).—Tests of the precautions which must be observed in order to obtain a phosphomolybdic pre-

epitrate of constant composition and to thus insure the accuracy of the determination are reported.

Investigations of the solubility of the phosphoric acid in some typical Swedish soils, G. NANNES (*K. Landtbr. Akad. Handl. och Tidskr.*, 44 (1905), No. 6, pp. 387-402).—Analyses of a number of Skaraborg County soils on which field trials were conducted showed that no sharp line can be drawn between available and nonavailable phosphoric acid by means of the solubility in 2 per cent acetic, citric, or hydrochloric acid, while the water-soluble phosphoric acid appeared to give valuable hints in this direction. This corroborates the results of T. Schloesing, jr. (*E. S. R.*, 14, p. 233), on this point.

The Dyer method for determining the available phosphoric acid by means of a citric-acid solution in the author's trials gave results corresponding with those of the field trials in the case of clay soils only, while for other types of soils no definite agreement in results could be traced.—F. W. WOLL.

On the chemical equilibrium observed when a number of bases are simultaneously associated with phosphoric acid, M. BERTHELOT (*Ann. Chim. et Phys.*, 8. ser., 8 (1906), July, pp. 289, 290).—This is a reply to a criticism in Quartaroli's article previously noted (*E. S. R.*, 17, p. 1036).

Analysis of nitrate of soda, R. BENSEMANN (*Ztschr. Angew. Chem.*, 19 (1906), No. 11, pp. 471-473).—Various modifications of the author's methods previously described (*E. S. R.*, 17, p. 952) to make them apply with more accuracy to potassium nitrate or to sodium nitrate rich in potash are explained.

On two new color reactions for nitric acid, C. REICHARD (*Chem. Ztg.*, 30 (1906), No. 65, pp. 790, 791).—The color reactions of berberin and arbutin are briefly described and their applications explained.

The investigation and valuation of fertilizers, feeding stuffs, seeds, and soils by the official methods of the Association of German Agricultural Experiment Stations, P. KRISCHE (*Die Untersuchung und Begutachtung von Düngemitteln, Futtermitteln, Saatwaraen und Bodenproben nach den offiziellen Methoden des Verbandes landwirtschaftlicher Versuchsstationen im Deutschen Reich*. Berlin: Paul Parey, 1906, pp. 242, figs. 5).—A summary of these methods.

Methods of determining carbon dioxide, W. HOLTSCHMIDT (*Chem. Ztg.*, 30 (1906), No. 50, pp. 621-625, figs. 3).—The author explains various ways in which the use and application of a modification of the method of Stutzer and Hartleb (*E. S. R.*, 11, p. 110), in which acid potassium tartrate is substituted for ammonium chlorid for expelling carbon dioxide, may be extended, and describes different forms of distilling apparatus suited to the methods described.

On the determination of carbon dioxide in waters, G. BRUIJNS (*Ztschr. Analyt. Chem.*, 45 (1906), No. 8, pp. 473-488; *abs. in Chem. Centralbl.*, 1906, II, No. 12, pp. 1019, 1020).—A modification of the Pettenkofer lime-water method, using either lime water or baryta water, and a special form of apparatus are described.

On the reliability of the Baudouin reaction, K. RÖRDAM (*Tidsskr. Landökonom.*, 1906, No. 6, pp. 373-378).—A review of recent work in regard to this question, leading to the conclusion that further investigations are required to determine the value of the method for the detection of artificial butter, especially in view of the periodicity of the sesame-oil reaction in human milk observed by Engel (*E. S. R.*, 17, p. 1006).—F. W. WOLL.

Formaldehyde: Its composition and uses, B. H. SMITH (*U. S. Dept. Agr. Yearbook 1905*, pp. 477-482).—Notes are given on the general properties of formaldehyde and the use of this material as a disinfectant, deodorant, fungicide, and preservative. Analyses of 29 commercial samples collected from dif-

ferent parts of the United States showed an average formaldehyde content of approximately 37 per cent.

Paints and their composition, E. F. LADD and C. D. HOLLEY (*North Dakota Sta. Bul.* 70, pp. 51-136).—In compliance with the State law the station is undertaking the examination, so far as possible, of all the brands of paint offered for sale in the State. One bulletin on this subject has already been published (E. S. R., 17, p. 636). The present bulletin contains analyses of a large number of paints, with information concerning frauds practiced, such as short weight, the cost of paints, trade and chemical names of the principal paint pigments, etc.

Report of the chemical laboratory of the Swedish Moor Culture Society, 1905, H. VON FEELITZEN (*Svenska Mosskulturför. Tidskr.*, 20 (1906), No. 3, pp. 163-188).—The results of analyses of 1,024 samples of moor soils, peat fuel, peat litter, lake mud, fertilizers, and miscellaneous agricultural products are given in the report.—F. W. WOLL.

Report of the chemist: Division of foods and feeding, J. B. LINDSEY (*Massachusetts Sta. Rpt.* 1905, pp. 65-78).—Statements are made concerning the extent and character of the work of this division during the year. Of the 1,635 pieces of dairy glassware examined 197 were condemned on account of inaccurate graduation.

METEOROLOGY—WATER.

Meteorological reports, C. C. GEORGESON (*U. S. Dept. Agr., Office Expt. Stat.* Bul. 169, pp. 7, 40, 55, 60, 94-100).—Tabular summaries are given of the reports of the volunteer weather observers of the Weather Bureau of Alaska on temperature, precipitation, and general weather conditions during the year ended September 30, 1905, and the general weather conditions at the experiment stations at Sitka, Copper Center, Rampart, and Kenai are briefly discussed.

Meteorological statistics for 1905, F. H. LOUP (*Colo. Col. Pub.*, 12 (1906), *Sci. Ser.*, Nos. 47-49, pp. 275-305).—The instrumental equipment and methods of making observations at the observatory of Colorado College are briefly described and a detailed daily, monthly, and annual summary of observations on temperature, atmospheric pressure, precipitation, humidity, winds, and sunshine is given.

Colorado Springs weather records between 1872 and 1903, C. M. ANGELL (*Colo. Col. Pub.*, 12 (1906), *Sci. Ser.*, Nos. 47-49, pp. 306-318).—Tables give mean monthly temperature, maximum and minimum daily temperature, mean of maximum and minimum daily temperatures, maximum daily range of temperature, total monthly wind movement, maximum wind velocity, prevailing monthly wind direction, mean monthly relative humidity, total monthly precipitation, maximum daily precipitation, and number of clear, partly cloudy, and cloudy days compiled from records of the observatory of Colorado College and of the Denver office of the U. S. Weather Bureau.

Meteorological observations, J. E. OSTRANDER and T. A. BARRY (*Massachusetts Sta. Met. Buls.* 211, 212, pp. 4 each).—Summaries of observations at Amherst, Mass., on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during July and August, 1906. The data are briefly discussed in a general note on the weather of each month.

The weather for 1905, S. B. DOTEN (*Nevada Sta. Bul.* 60, pp. 19, chart 1).—An account is given by months of the weather conditions during the year 1905, with an annual summary in which the records for 1905 are compared with those for the preceding 17 years.

The data reported include observations on temperature, precipitation, cloudi-

ness, and direction of the wind. The average temperature for the year was 49.5° F., the highest temperature 98°, July 9, the lowest 7°, December 24. The total precipitation was 5.69 in., being 2.51 in. less than the normal for 17 years. There were 222 clear days during the year. There was an average daily range in temperature of 29°, the greatest variation being during the cloudless months of July and August, when the daily range was 36°, and least in January and February, when the average daily variation was 23°.

This great daily range of temperature is an important and characteristic feature of the climate of this region. "In the spring it endangers the fruit crop, for warm, sunny days are followed by nights cloudless and cold, when the frost plays havoc with bud and blossom. . . . [It] certainly has its bad influences on agriculture in this vicinity, but it is equally certain that it forms in other ways one of the most pleasant and beneficial features of our climate."

Annual precipitation in Oklahoma and Indian Territory, J. P. SLAUGHTER (*Oklahoma Sta. Rpt. 1906, pp. 57, 58*).—Tabular summaries are given of annual precipitation at various places in Oklahoma and Indian Territory during the period 1889 to 1905.

Meteorology, T. M. CARPENTER and N. C. HAMNER (*Pennsylvania Sta. Rpt. 1905, pp. 60-70, 213-234*).—The observations here recorded are of the same character as those reported in previous years (E. S. R., 17, p. 222). Monthly summaries of observations are given in the body of the report and the detailed record in an appendix. The summary for 1904 is as follows:

Summary of meteorological observations, 1904.

	1904.	Growing season (Apr.-Sept.).
Barometer (inches):		
Mean	30.086	
Highest	30.779 (Mar. 7)	
Lowest	29.305 (Mar. 8)	
Temperature (° F.):		
Mean	45.7	61.1
Highest	89 (July 18)	89 (July 18).
Lowest	-15 (Jan. 5)	19 (Apr. 14).
Mean daily range	17.5	18.8.
Greatest daily range	43 (May 12)	43 (May 12).
Least daily range	1 (Jan. 27)	
Mean daily relative humidity (per cent)	80.8	80.3.
Rainfall (inches):		
Total	36.03	21.61.
Greatest monthly	6.30 (July)	
Greatest daily	1.79 (July 10)	1.79 (July 10).
Number of days on which 0.01 in. or more of rain fell	150	81.
Mean percentage of cloudiness	51.3	48.3.
Number of days on which cloudiness averaged 80 per cent or more	122	51.
Average hours of sunshine per day		5 h. 50 min.
Last frost in spring		May 12.
First frost in fall		Sept. 16.

Meteorological conditions in Denmark, 1904-5, V. WILLAUME-JANTZEN (*Tidsskr. Landökonom., 1905, No. 10, pp. 517-532*).

Extension of the river and flood service of the Weather Bureau, H. C. FRANKENFIELD (*U. S. Dept. Agr. Yearbook 1905, pp. 231-240, pl. 1*).—The early history, recent extension, and present status of this service is fully explained. Beginning with the year 1904 there has been rapid extension of the service, so that at the end of 1905 there were 426 river stations and 120 rainfall stations, covering all of the principal watersheds of the United States and making adequate provision for the present needs of the service.

The following lines along which further improvement and extension may be made are discussed in detail: "(1) Geology and topography of the water-

sheds: (2) snowfall, its distribution, character, and water equivalent, the last being of essential importance; (3) forest influences, their character and extent; (4) underflow or ground water, its character and extent; (5) evaporation, its amount, seasonal distribution, and modification by winds, weather, and temperature; (6) discharge volumes as affected by all the above conditions; (7) distribution of river forecasts and information."

Some notes upon the influence of the shelter tent upon temperature and moisture, W. FREAR (*Pennsylvania Sta. Rpt. 1905*, pp. 34-38, *dgms.* 3).—Data are recorded for observations on temperature inside and outside of a shelter tent used for the growing of Sumatra tobacco during the week beginning August 31, 1902, and on soil moisture inside and outside of the tent during the period from July 21 to September 11.

The temperature observations show that during the night the temperature inside and outside of the tent was very nearly the same. At midday, however, the temperature inside the tent was considerably higher than outside on days of bright sunshine, a difference of 18° being observed at 3 p. m. of September 5. The soil moisture determinations showed in general that the soil under the shelter was always more moist than that in the open air except some time after heavy rains, the difference amounting on the average to 1.6 per cent, "corresponding to one-eighth of the entire average amount in the unsheltered soil, a difference sufficient to influence plant growth very materially."

Certain relations of rainfall and temperature to tree growth, H. GANNETT (*Bul. Amer. Geogr. Soc.*, 38 (1906), No. 7, pp. 424-434; *abs. in Science*, n. ser., 24 (1906), No. 611, p. 345).—The author "finds that the timber line has a mean annual temperature of approximately 30°, but the data relating to rainfall are more definite and more significant than those of temperature. It appears that the lower limit of the yellow pine is at or just below 20 in. of rainfall. The lower limit of the red fir is at or about 30 in., and there is apparently no upper limit, the fir being abundant where the rainfall exceeds 100 in. a year. The redwood belt in California includes only one station with a rainfall less than 30 in. This seems to show that the isohyetal line of 30 in. is the lower limit of this species."

Cyclonic storms and Rochester weather, H. L. FAIRCHILD (*Proc. Rochester Acad. Sci.*, 3 (1906), No. 3, pp. 301-316, *figs.* 2).—This article contains a general discussion of meteorological elements which go to make climate and of the two main types of climate, continental and oceanic, and summarizes observations at Rochester during the last 25 to 30 years on temperature, precipitation, cloudiness, winds, etc. The nature and movement of cyclones with special reference to Rochester conditions are also explained.

Tar smudge, A. M. THACKARA (*Mo. Consular and Trade Rpts. [U. S.]*, 1906, No. 309, pp. 83, 84).—Trials of a patented tar smudge for protection of fruit against frost are briefly reported.

Guide to the weather, R. BÖRNSTEIN (*Leifaden der Wetterkunde. Bruns- wick: Friedrich Vieweg and Son. 1906*, 2. ed., *rev. and enl.*, pp. 230; *rev. in Amer. Jour. Sci.*, 4. ser., 22 (1906), No. 127, pp. 81, 82).

Amount of chlorin in rain water, W. P. JORISSEN (*Chem. Weekbl.*, 3 (1906), pp. 42, 43; *abs. in Chem. Centbl.*, 1906, I, p. 698; *Jour. Chem. Soc. [London]*, 90 (1906), No. 525, II, p. 486).—"As a result of 92 experiments the author has found that, in certain districts near the North Sea, the mean proportion of chlorin in rain water is about 29.6 mg. of chlorin per liter."

Chlorin in rain water (*Agr. Students' Gaz.*, n. ser., 13 (1906), No. 1, p. 26).—The rainfall at the agricultural college, Cirencester, for the 6 months ended March 31, 1906, was 13.33 in., falling on 99 days, and contained chlorids equivalent to 14.26 lbs. of common salt per acre; for the 12 months ending on the same

date the rainfall was 26.77 in., falling on 182 days, and containing the equivalent of 26.22 lbs. of common salt per acre.

Composition of Indian rain and dew, J. W. LEATHER (*Mem. Dept. Agr. India, Chem. Ser., 1 (1906), No. 1, pp. 11; abs. in Jour. Chem. Soc. [London], 90 (1906), No. 525, II, p. 487*).—“Determinations of nitrogen as ammonia and as nitrates and nitrites in samples of rain water (generally two per month) collected at Dehra Dun from January to December, 1904, and at Cawnpore from May 1, 1904, to April 30, 1905.

“The dew collected in a large gage ($\frac{1}{1000}$ acre) at Cawnpore from September 16, 1904, to March 15, 1905, amounted to 0.170 in. and contained nitrogen ammonia=0.055 and nitric nitrogen=0.056 lb. per acre, the amounts per million varying from 0.85 to 2.65 and 0.51 to 4.12, respectively.”

The prevention of the growth of algæ in water supplies (*Engin. Rec., 54 (1906), No. 10, pp. 263, 264*).—An abstract is given of a paper presented at the last annual meeting of the Royal Sanitary Institute by S. Rideal and R. Orchard, reporting results of comparative tests of Moore's copper sulphate method and treatment with electrolytic chlorin. The use of 1.2 parts of the latter per million parts of water was more effective than 1 part of copper sulphate per million. The chlorin treatment is considered an effective means of preventing green growths in water and of destroying a large proportion of microscopic plants which are found in water.

A study of the numbers of bacteria developing at different temperatures and of the ratios between such numbers with reference to their significance in the interpretation of water analysis, S. DE M. GAGE (*Boston, 1906, pp. 223-257*).—This is a reprint from Biological Studies by the Pupils of William Thompson Sedgwick.

In the investigations reported in this paper 17 different classes of samples of water were examined. These classes and the methods used in their investigation are described.

The results obtained lead to the conclusion that “nearly all of the information desired concerning the bacterial content of water may be obtained by the use of selective media, by the use of selective temperatures, or by a proper combination of the two. In the present investigation the selective action of four different temperatures, 20°, 30°, 40°, and 50° C., and two different media, regular agar, and litmus-lactose agar, in determining the bacteriological contents of a number of different kinds of water, have been studied; and while the results obtained have been in many cases inconclusive, and in other cases too few in number to warrant the drawing of any far-reaching conclusions, they indicate in a measure the procedures which must be followed in order to place the bacteriological analysis of water on the same plane as the chemical analysis.”

The substitution of litmus-lactose agar for agar or gelatin as culture medium is recommended on the ground that the former permits the simultaneous determination of the total bacteria and of the acid-producing organisms without appreciably increasing the labor involved. “The numbers of the two classes of bacteria so determined indicate more completely the character of the water than would the numbers of either class determined alone.”

The total number of bacteria determined at 20° C. is not of special significance, but the number of acid-producing organisms at this temperature is an important check upon the total numbers. The number of bacteria and of acid-producing organisms determined at 30° C. after 24 hours' incubation affords a means of more sharply distinguishing between polluted and pure waters than the numbers determined at lower temperatures. “The numbers of bacteria determined at 40° C. are of great interest, since in this class of bacteria must be included the disease-producing organisms. The distinction between waters of different

kinds and between waters of the same kind representing different degrees of pollution is well marked by counts at this temperature.

On the progress of self-purification in water, HOFFER (*München. Med. Wehnschr.*, 52 (1905), pp. 2266-2269; *abs. in Chem. Centbl.*, 1906, 11, No. 7, p. 637).—A discussion of chemical and biological processes with special reference to the Isar.

SOILS—FERTILIZERS.

Studies of Wisconsin soils, A. R. WHITSON and C. W. STODDART (*Wisconsin Sta. Rpt.*, 1905, pp. 262-281, figs. 9, map 1).—The soils of the State are classified, chiefly according to origin, and the different classes are described and mapped as follows: (1) Red clay, chiefly of lacustrine origin, (2) last glacial clay on crystalline rock, (3) old glacial clay on crystalline rock, (4) last glacial clay on limestone and sandstone, (5) old glacial clay on limestone and sandstone, (6) residual clay on limestone, (7) sandy soils of last glacial period, (8) residual sandy loam soils of Potsdam sandstone, (9) residual sandy soils of Potsdam sandstone, (10) loess or soils chiefly of wind origin, and (11) muck and peat soils.

The methods of chemical analysis used are described and the results of analysis of the different type soils are briefly reported, and an experiment begun by F. H. King, in which a study has been made of the changes which take place during the exhaustion of soil fertility by continuous cropping, is reported. In these experiments a virgin soil has been cropped practically continuously for 8 years in cylinders 18 in. in diameter and 42 in. in depth, 20 of the cylinders being cropped with corn, 8 with oats, 6 with potatoes, and 14 with common red clover.

To determine the fertilizing constituents in which the soil was deficient various kinds and combinations of fertilizing materials were applied to the soil, and chemical analyses were made of the soil at the beginning and end of the series of experiments. The results show that the supply of available potash was more completely exhausted than that of any other element, although in the case of oats the available nitrogen and phosphoric acid were also insufficient. Chemical analysis showed that the most noticeable change which had taken place in the soil was the reduction of the organic matter from 3.24 per cent to 2.22 per cent "and suggests that the potassium which has been used by the plants grown on this soil has come chiefly from the organic matter which has been decomposed."

Experiments with peat soils which were begun in 1904 (*E. S. R.*, 16, p. 755) were continued during 1905 on a farm at Marinette, Wis., the object of the experiments during this year being "first, to determine the fertilizer requirements of the soil in its virgin condition; second, the availability of untreated rock phosphate; third, the relative adaptability of different grasses for hay; and, fourth, the effect of ground limestone used to neutralize the acidity of this soil."

Experiments with grasses, barley, and oats are briefly reported. The season was unfavorable and the results are considered inconclusive.

[Acidity and nitrogen in Hawaiian soils], E. C. SHOREY (*U. S. Dept. Agr., Office Expt. Stas. Bul.*, 170, pp. 28-37).—A brief preliminary report is given on acidity determinations in 25 samples of soils by the method of Hopkins, Knox, and Pettit. Only 2 samples were acid to litmus paper, but all gave acid solutions when extracted with 5 per cent salt solution. The acidity apparently did not interfere to any great extent with nitrification, since the soils examined contained from 15 to 55 parts per million of nitrates. It was observed that

there was a large decrease in nitrates when a soil was allowed to stand for some time in contact with water. The greatest amount of nitrates at the end of 24 hours was found in soil to which about two-thirds of the water required for saturation had been added and declined as saturation was approached. The addition of a small amount of chloroform or heating of the soil after saturation with water to 125° C. for 5 minutes prevented this change of nitrates in case of all the soils examined.

Investigations are reported which indicate that excessive rains do not wash the nitrates from the soil as rapidly as has been supposed. "While the samples of soil examined in this work have not been numerous, extreme types have been included from different islands, and the data obtained are sufficient to warrant the assertion that a widespread characteristic of Hawaiian soils is that when they are at or near the saturation point with respect to water there is a change of nitrates and an apparent fixation of a portion of the nitric nitrogen in a form not easily soluble."

Previous investigations on the constitution of the nitrogenous compounds in Hawaiian soils were continued. It was found that while the percentage of nitrogen compounds in the soils is large, their solubility in water is low although more readily soluble in hot acids and alkalis. Hot acid solutions were studied by the Osborne and Harris method. The striking point observed was the large amount of nitrogen contained in the magnesia precipitate and the conclusion was reached "that in the soil nitrogen which is soluble in boiling acids a portion, approximately 50 per cent, is in a form unlike, for the most part, the products of decomposition of protein bodies with acids."

On dry distillation the soils rich in nitrogen examined gave an alkaline distillate containing ammonia, as well as pyridin and some of its homologues not yet identified. The author believes that the pyridin exists in some form in the soil and reports some preliminary studies of oxidation of the soil by neutral and alkaline permanganate, which, however, yielded no very definite results.

The exploitation of peaty soils, F. NICOLLE (*Jour. Agr. Prat., n. ser., 11 (1906), No. 25-26, pp. 758-761*).—The methods of reclaiming and bringing under cultivation of such soils are briefly discussed, especially methods of drainage and fertilizing. Fertilizer experiments on peaty soils are cited as indicating that although potash is deficient in many cases, peaty soils are as a rule more benefited by phosphatic fertilizers, particularly phosphatic slag, than by potash fertilizers.

Shifting sands, W. S. BURGE (*Amer. Inventor, 15 (1906), No. 9, pp. 230, 231, figs. 4*).—A brief account of the work of this Department on Cape Cod, Massachusetts, with sand-binding grasses.

Soil temperatures, C. C. GEORGESON (*U. S. Dept. Agr., Office Expt. Stas. Bul. 169, pp. 91-93*).—Readings at 7 a. m. of thermometers 6 in. above the ground and 6 and 24 in. below at the experiment stations at Sitka, Copper Center, and Kenai during the season of 1905 are reported.

Hints for agricultural associations (*Cent. Agr. Com. Madras Circ. 6, pp. 5*).—Among the more important subjects briefly discussed in this circular are reclamation of alkali land, the use of various kinds of manures, tillage, irrigation, new crops, and cultural methods. The means which it is claimed have been successfully employed in India for reclaiming alkali lands include hurdling cows on the area and thus allowing the manure to accumulate, green manuring, fencing to increase growth of natural herbage, use of crude calcium nitrate from artificial niter beds, plowing in paddy straw (on wet alkali lands), and application of gypsum. The artificial preparation of niter is explained.

The improvement of wet and alkali meadows, J. FARCY (*Jour. Agr. Prat., n. ser., 11 (1906), No. 18, pp. 565, 566*).—Methods of drainage, irrigation, and fertilizing which will correct the unsatisfactory conditions are briefly described.

Investigations on the insoluble alkali compounds existing in the humus substances of the soil and their rôle in plant physiology and agriculture, M. BERTHELOT (*Ann Chim. et. Phys.*, 8. ser., 8 (1906), *May*, pp. 5-9; *abs. in Chem. Ztg.*, 30 (1906), No. 58, *Repert.* No. 22, p. 232).—See E. S. R., 17, p. 644.

The removal of salts from soils in Egypt, R. ALADJEM (*Jour. Agr. Prat.*, n. ser., 12 (1906), No. 33, pp. 215, 216).—The methods of flooding and drainage employed for this purpose are described.

A saline soil of the lower valley of the Po, V. P' EGLION (*Atti R. Accad. Econ. Agr. Firenze*, 5. ser., 3 (1906), No. 1, pp. 59-64).—The proportion and the composition of the soluble salt (alkali) in the soil are reported.

On the absorption of alkaline carbonates by the mineral constituents of soils, J. DUMONT and L. MAQUENNE (*Compt. Rend. Acad. Sci. [Paris]*, 142 (1906), No. 6, pp. 345-347; *abs. in Rev. Sci. [Paris]*, 5. ser., 5 (1906), No. 7, p. 210; *Jour. Chem. Soc. [London]*, 90 (1906), No. 522, II, p. 249).—The extent of absorption due to chemical changes was determined by measuring the amount of carbon dioxide evolved when a solution of potassium carbonate was added to moistened clay, fine sand, kaolin, silica, iron hydrate, and alumina, and allowed to stand for some time.

The results indicate that the sandy constituents of soils do not exert any decomposing action on alkaline carbonates; kaolin acts very feebly in this respect; silicic acid even when dried decomposes potassium carbonate in the cold, but to a less extent than other colloidal substances; hydrates of iron and aluminum act very energetically, and the action of alumina particularly is in all respects comparable with that of clay. It appears that the absorbent property of clay exceeds that of its constituents taken individually or collectively.

In a note on this article Maquenne maintains that the absorbent property of clay is due to and is a necessary consequence of its chemical composition. The position of the OH groups in clay is such that the latter can form with both bases and acids, compounds which are probably dissociable by water.

On the influence of bacteria on the metamorphosis of nitric acid in soils, J. STOKLASA and E. VITEK (*Ztschr. Landw. Versuchs. Österr.*, 9 (1906), No. 2, pp. 49-105).—The authors' investigations with a great variety of organisms in different media lead to the conclusion that nitrous acid is always the intermediate product in the reduction of nitrates by these organisms. It was found that carbon dioxide and hydrogen are produced from the carbohydrates or organic acids of the culture media and that the nascent hydrogen combines with the oxygen of the nitrates to form water and thus reduces the latter to nitrites. A hypothetical scheme for such breaking down of glucose with production of hydrogen is given. In the same way denitrifying organisms reduce chlorates to chlorides, arsenates to arsenites, ferricyanids to ferrocyanids.

Certain of the most widely distributed carbohydrates in soils and manures, as for example, xylose and arabinose, are not specially good nutrients for denitrification bacteria, but favor slow ammonisation of nitric and nitrous acids. It is true, however, that the typical denitrifying organism *Bacillus hartlebii* in a medium containing arabinose was able to assimilate 33.62 per cent of the nitrogen of nitrate and convert it into protein substances. The soil also frequently contains carbohydrates, such as the hexoses, and organic acids, which favor denitrification. Nevertheless, denitrification as a rule plays only a secondary rôle to nitrification and ammonisation in soils.

The authors' studies of a number of beet soils showed that the ammonisation bacteria predominated in them, *Clostridium gelatinosum* being especially prevalent, but associated with other organisms which play an important part in con-

verting nitrate nitrogen into ammonia nitrogen, viz, *Bacillus mycoides*, *B. subtilis*, *B. mesentericus*, and others.

It was found that *Clostridium gelatinosum* in an arabinose medium converted 46 per cent of nitrate nitrogen into ammonia nitrogen and utilized about 6 per cent of the nitrogen in the production of protein substances.

[**Indian soils and fertilizers**], J. W. LEATHER (*Ann. Rpt. Imp. Dept. Agr. [India], 1904-5, pp. 53-63, fig. 1*).—The work of the agricultural chemist to the Government of India during the year ended June 30, 1905, and during previous years is summarized, including studies of available plant food in soils, alkali, combined nitrogen in rain and dew, amount and nitrate content of drainage water, composition of well and canal waters, composition of manures, purification of sewage, composition of canal silt, and methods of artificial preparation of saltpeter.

The soil studies indicate that nitrogenous manures are generally needed by Indian soils, the sulphates vary widely and are sometimes deficient; in the usar or alkali soils the proportion of alkali in the upper 6 or 12 in. rarely exceeds 1 to 2 per cent and is commonly much less. The principal constituents of the alkali are sodium carbonate and bicarbonate, silicate, sulphate and chlorid, and magnesium sulphate and chlorid are occasionally present. The greatest injury is caused by the sodium carbonate, both by its corrosive action and by its bad effect on drainage. The most effective remedies for alkali which have been tried are good cultivation combined with heavy manuring and the application of gypsum. Drainage has not proved successful on account of the silting up of the tile. The gypsum treatment is too expensive for general use on very bad land.

The total nitrogen in the annual rainfall (87.45 in.) at Dehra Dun was 3.596 lbs. per acre and at Cawnpore (49.36 in.), 3.25 lbs. Dew was much richer in nitrogenous compounds than rain water (2 to 4 parts per million). The proportion of nitric nitrogen was relatively larger in dew than in rain. It usually equaled and sometimes exceeded the ammonia, the reverse of what would be expected. Percolation at Cawnpore was the same from a 3-ft. drain gage as from a 6-ft. gage.

The amount of nitric nitrogen removed per year in drainage water from bare soil was about 74 lbs. per acre for the 3-ft. gage and 123 lbs. for the 6-ft. gage.

It is reported that examination of certain well waters from Gujarat, which had been found to have a particularly beneficial effect on tobacco, showed the presence of large amounts of potassium, sodium, and calcium nitrates. The proportion of nitrates was so large that the waters could not be used without previous dilution.

The investigations on sewage reviewed in this article have already been referred to in the Record (E. S. R., 15, p. 762). One of the principal objects of these investigations was to ascertain the rate of hydrolyzation of organic nitrogen in septic tanks and of purification in contact beds. It was found "that the rate of change was considerably greater when the concentration of this organic nitrogen was high than when it was low, and that for a strong sewage a relatively smaller tank would be required than for a weak sewage. Secondly, there seemed to be a limit to the destruction of this organic matter. . . . After the amount of this nitrogen had fallen to about 1 part per 100,000 (hundred thousand), no further diminution occurred. . . . Out of every 100 parts of nitrogen in the fresh sewage, from 10 to 20 were lost in the septic tank, and a further 10 to 20 were lost in the bacteria bed treatment. The total loss experienced varied from 30 to 40 parts. The magnitude of this loss has not apparently any relation to the strength of the sewage, for it was nearly as great when the weak as when the strong sewage was being treated."

Examinations of canal water used for irrigation of wheat, rice, and sugar cane showed that during the flood season the silt in the amount of water used on rice would carry as high as 32 lbs. of nitrogen and 42 lbs. of phosphoric acid. The amount used on the wheat crop, however, would probably furnish not more than 5 lbs. each of nitrogen and phosphoric acid.

The process of percolation employed in Indian saltpeter works to obtain a strong, almost saturated, solution of salts is briefly described, and a study of the composition of "sitta," a product obtained in the process of refining the saltpeter, is reported. The product is mainly sodium chlorid, but often contains admixtures of from 2 to 14 per cent of saltpeter, which mainly determines its agricultural value.

Plan for a soil test with fertilizers, W. FREAR (*Pennsylvania Sta. Rpt. 1905, pp. 22-25, pl. 1*).—A plan of an experiment to determine the most profitable kinds of fertilizing materials to apply to corn or wheat is described.

Cooperative fertilizer trials in Sweden, 1905, P. BOLIN (*K. Landtbr. Akad. Handl. och Tidskr., 1906, Bihang, pp. 121*).—The fertilizer trials discussed in this report were conducted in 14 different counties by county agricultural societies in cooperation with the Royal Agricultural Academy. Two hundred and fifty-four different trials, including about 7,000 plats in the aggregate, were conducted, viz. 130 trials with spring grains, 88 with root crops, 35 with pastures or meadows, and 1 with winter grains. The general plan of the trials was similar to that of earlier years (see E. S. R., 15, p. 569; 17, p. 654). The report contains complete details as to the conditions under which the individual trials were conducted, the system of fertilization adopted, and the results obtained, with general discussions of the latter.

Among special trials conducted during the year the following may be noted:

Comparative trials with ammonium sulphate and nitrate of soda.—These trials were conducted with potatoes (9 trials), mangels (5 trials), fodder beets (3 trials), and oats (8 trials). The fertilizers were applied at the rate of either 35 or 25 lbs. of nitrogen per acre for the crops mentioned, except for oats, which received nitrogen at the rates of 25 and 12.5 lbs. per acre. In the case of the former crops, 356 lbs. of superphosphate and 178 lbs. of potash salt per acre were applied, in addition to the nitrogen fertilizer, and for oats, 267 lbs. of superphosphate and 89 lbs. of potash salt. If the increase in yields produced by the nitrate of soda over that on the control plats be taken as 100, the effect of the ammonium sulphate was, on the average, as follows for the various crops: Heavy nitrogenous fertilization—potatoes 63, mangels 78, fodder beets 71, and oats, grain 97, straw, 78; light nitrogenous fertilization—potatoes 54, mangels 60, fodder beets 77, and oats, grain 78, straw 63. The effect of the ammonium sulphate in this year's trials, on the average for all trials and all crops, was equal to 72 per cent of that of a corresponding amount of nitrate of soda.

Comparative trials with cyanamid, lime niter, ammonium sulphate, and nitrate of soda.—The first fertilizer contained about 20 per cent of nitrogen, and the second one (Birkeland and Eyde process) about 11 per cent. Only one of the series of trials planned was carried through successfully, viz. with oats on clay soil. The results obtained showed that for this crop and soil the fertilizer value of the lime niter was fully equal to that of the nitrate of soda, calculated on the same quantities of nitrogen, and that the action of the cyanamid is quite similar to that of ammonium sulphate.

On the best time of liming fallow ground.—A field of clay soil seeded to rye on August 16, 1904, was divided into plats, some of which were manured and limed, while others were either manured or limed only. The manure was applied June 14, and the slaked lime (3,000 kg. per hectare) either on the same

date or August 16. The best results both as regards grain and straw were obtained on the manured and limed plats where the lime was applied on the latter date. The lime applied at the time of manuring did not produce as good results as manure alone, there being an average increase in grain over the yield on the plats neither manured nor limed amounting to 270 kg. per hectare in the latter case against 170 kg. in the former and 470 kg. in the case of the manured plats that were limed August 16. The lime alone (applied August 16) did not produce any beneficial effect, the yield obtained being even somewhat lower than that of the control plats which were neither manured nor limed. The results show plainly that lime will give best results on fallow ground when applied late in the fall.—F. W. WOLL.

The assimilation of mineral matter by different crops in vegetation experiments with calcareous manures carried on from 1896 to 1903, R. ULBRICHT (*Landw. Vers. Stat.*, 63 (1906), No. 5-6, pp. 321-374; *abs. in Jour. Chem. Soc. [London]*, 90 (1906), No. 523, II, p. 304).—This article reports plat and pot experiments with lime, marl, and limestone on potatoes, oats, corn, rye, barley, rape, yellow lupine, vetch, red clover, and serradella in continuation of those of previous years (E. S. R., 15, p. 860; 16, p. 32). The influence of the different calcareous manures on the growth and plant food assimilation of the crops is discussed in detail, especially in case of the leguminous crops.

“Application of lime resulted in a slightly diminished assimilation of nitrogen and phosphoric acid in the case of lupines, vetches, and serradella, whilst the potassium was increased in lupines and serradella, but not in vetches. The magnesia in all three plants was considerably increased by manuring with calcium and magnesium carbonates and was distinctly increased even by burnt Carrara marble, which contains only small amounts of magnesium.”

Agricultural value of poultry manure, H. V. HAWKINS (*Year Book Agr. Victoria, 1905*, pp. 427, 428).—Observations with Dorkings, averaging 8 lbs. each, showed that the manure produced during the daytime amounted to 1½ oz. per bird, and during the nighttime 2 oz., or 46 lbs. per annum. The fertilizing value of well-cared-for manure is discussed and the best means of preserving the manure are explained.

Artificial fertilizers, F. E. LEE (*Year Book Agr. Victoria, 1905*, pp. 115-137, *figs. 12*).—This is a general discussion of the subject, including explanations regarding the need of fertilizers, the valuable constituents of fertilizers, the fertilizers on the Victorian market during 1905, hints on mixing artificial fertilizers, comparison of fertilizers with farmyard manure, the valuation of fertilizers, and a summary of the fertilizer law of Victoria.

Nitrogen from the air (*Mark Lane Express*, 94 (1906), No. 3897, p. 613).—This is a brief note on an address by P. A. Guye before the Society of Chemical Industry on the problem of the electro-chemical fixation of nitrogen. Attention is here called especially to the relative cost of nitrogen fixation by the calcium cyanamid and the electro-chemical methods. It was estimated that the cost of nitrogen fixed as calcium cyanamid will be about the same as that in the ammoniacal salts and the nitrates of Chile. Under present conditions the electro-chemical method is believed to be somewhat cheaper.

On the spontaneous formation of dicyandiamid in fertilizers containing calcium cyanamid, R. PEROTTI (*Atti R. Acad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat.*, 5. ser., 15 (1906), I, No. 1, pp. 48-53; *abs. in Chem. Centbl.*, 1906, I, No. 17, p. 1467; *Jour. Chem. Soc. [London]*, 90 (1906), No. 523, II, p. 304).—The author shows that when calcium cyanamid is exposed to moist air a portion of the nitrogen escapes as ammonia and a part is transformed into dicyandiamid. These changes are important because of the loss of nitrogen and also because the fertilizing value of the dicyandiamid has not been definitely determined.

Nitrate of soda as compared with a mixture of nitrate of soda and sulphate of ammonia, D. FERUGLIO (*Ann. R. Staz. Sper. Agr. Udine*, 8 (1906), pp. 72-76).—The results of plat experiments with wheat here reported indicate that the nitrate alone in 2 applications was more effective than a mixture of nitrate of soda and sulphate of ammonia.

The influence of soil bacteria on the solubility of the phosphoric acid of different phosphates. A. KOCH and E. KRÖBER (*Fühling's Landw. Ztg.*, 55 (1906), No. 7, pp. 225-235; *abs. in Chem. Ztg.*, 30 (1906), No. 34, *Reperit. No. 12*, p. 14).—Bacteriological and chemical studies with a large number of insoluble phosphates showed that bacteria produce acids which render such phosphates soluble. These acids must, however, first neutralize ammonia, lime, or calcium and magnesium carbonate, and similar substances which may be present. The bacteria work on all phosphates, but at varying rates, depending upon the composition. They work with particular rapidity on Thomas slag once the basic constituents are neutralized. A larger amount of acid is required, as a rule, than the chemical reaction would indicate. The better action of bone meal on humus soils is due not only to the solvent action of the humus and carbon dioxid but also to the greater activity of acid-forming bacteria in such soils. The application of lime neutralizes these acids and thus interferes with their solvent action on the phosphates.

Aluminum phosphate as compared with mineral superphosphate and Thomas slag, Z. BONOMI (*Ann. R. Staz. Sper. Agr. Udine*, 8 (1906), pp. 26-32).—Pot experiments on spring wheat and clover with these phosphates combined with other fertilizing materials are reported.

The aluminum phosphate used contained 20.48 per cent of phosphoric acid soluble in neutral citrate, 14.72 per cent soluble in Wagner's solution, 42.37 per cent soluble in alkaline citrate, and 45.56 per cent total phosphoric acid. The superphosphate contained 13.25 per cent of phosphoric acid soluble in neutral citrate, the Thomas slag 10.18 per cent soluble in neutral citrate and 13.89 per cent soluble in Wagner's citric-acid solution.

The results show that the aluminum phosphate produced a substantial increase of yield in case both of clover and wheat, but was always inferior to the superphosphate. In case of spring wheat the aluminum phosphate was inferior to the Thomas slag, but superior to it in case of the clover.

Calcium superphosphate as compared with Thomas slag, Z. BONOMI (*Ann. R. Staz. Sper. Agr. Udine*, 8 (1906), pp. 38-65, pl. 1).—Comparative field tests are reported of Thomas slag containing 14.5 per cent of phosphoric acid soluble in citric acid and 10 per cent of free lime, and mineral superphosphate containing 9.38 per cent of phosphoric acid soluble in water and 13.18 per cent soluble in neutral citrate solution. The results show in general that the Thomas slag was the more economical fertilizer, but in many cases the superphosphate supplemented by applications of lime gave larger increase in yield.

The economical use of potash fertilizers, Z. BONOMI (*Ann. R. Staz. Sper. Agr. Udine*, 8 (1906), pp. 77-87).—The results of field experiments on red clover were somewhat inconclusive. Although the use of potash fertilizers in all cases increased the yield, in many cases this was not sufficient to return the cost of the fertilizer. The author therefore concludes that potash fertilizers should be used with caution.

Sulphate of potash, L. BARGERON (*Jour. Agr. Prat.*, n. ser., 11 (1906), No. 21-22, pp. 667, 668).—This article discusses briefly the sources, manufacture, and consumption of this salt, as well as the relative economy of sulphate and chlorid of potash.

Salt, F. E. ENGELHARDT (*Syracuse, N. Y.: Author* [1906], pp. 15).—An account is given of the formation of salt deposits in general and of the discovery

and character of the deposits in the United States, with a more detailed account of the rise and decline of the Syracuse salt industry and the borings made to discover the source of the Onondaga brines.

Fertilization, R. J. REDDING and H. N. STARNES (*Georgia Sta. Bul. 72, pp. 121-143*).—“The purpose of this little bulletin is to furnish a handy manual for the use of farmers concerning the methods of culture of the leading farm, orchard, and garden crops of the South, and the formulation of fertilizers for the same. . . . The suggestions and formulas are largely based on carefully conducted experiments in the field, orchard, and garden, some of them many times repeated, on the Georgia Experiment Station farm. They are here compiled, with amendments, from previous bulletins that have appeared from time to time during the last 15 years.”

Analyses of fertilizers, C. A. GOESSMANN (*Massachusetts Sta. Bul. 111, pp. 28*).—This bulletin gives market values of fertilizing ingredients and reports analyses of licensed fertilizers collected in the general market and miscellaneous fertilizing materials sent to the station for examination, including wood ashes, lime ashes, prepared lime, oyster-shell lime, nitrate of soda, sulphate of ammonia, nitrate of potash, saltpeter waste, dried blood, linseed meal, cotton-seed meal, high-grade sulphate of potash, potash magnesia sulphate, carbonate of potash and magnesia, dissolved boneblack, acid phosphate, burned bone, phosphatic slag, dissolved bone, ground bone, fine-ground bone and tankage, tankage, dry ground fish, bone waste, horn waste, beef scrap, sheep manure, cotton waste, sludge from filter beds, manure and lime, leather refuse, Chincha Peruvian guano, Lobos Peruvian guano, compound fertilizers, and soils.

Compilation of analyses of agricultural chemicals, refuse salts, ashes, lime compounds, refuse substances, guanos, phosphates, and animal excrements, H. D. HASKINS (*Massachusetts Sta. Rpt. 1905, pp. 155-183*).—This is a compilation of analyses made at the Massachusetts Agricultural College and Experiment Stations, 1868 to 1905, inclusive. It does not include analyses of licensed fertilizers.

Report on official inspection of commercial fertilizers and agricultural chemicals during the season of 1905, C. A. GOESSMANN (*Massachusetts Sta. Rpt. 1905, pp. 50-69*).—The results of examinations of 511 samples representing 313 brands are summarized. Tables show the average composition of the different classes of all fertilizer analyses, and the maximum, minimum, and average composition of special crop fertilizers. A schedule of trade values of fertilizing constituents and a list of licensed manufacturers and dealers are given.

Report on general work in the chemical laboratory, C. A. GOESSMANN (*Massachusetts Sta. Rpt. 1905, pp. 61-64*).—Brief notes are given on the examination of wood ashes and lime ashes.

Fertilizer analyses, fall season, 1905, to spring season, 1906, B. W. KILGORE (*Bul. N. C. Bd. Agr., 27 (1906), No. 7, pp. 83*).—The names and guaranteed composition of fertilizers registered for 1906, and analyses and valuations of 750 samples of commercial fertilizers and 76 samples of cotton-seed meal examined during the fall of 1905 and spring of 1906, with explanations regarding terms used in fertilizer analyses, freight rates, valuation, etc.

Analyses of commercial fertilizers (*South Carolina Sta. Bul. 119, pp. 37*).—This bulletin contains the analyses of 655 samples of fertilizers collected during the season of 1905-6. “These analyses were published in 20 weekly bulletins issued and distributed during the months of February, March, April, and May.”

Inspection of commercial fertilizers, 1905, F. W. WOLL and G. A. OLSON (*Wisconsin Sta. Rpt. 1905, pp. 377, 378*).—Analyses of 15 samples of fertilizers licensed for sale in the State during the year are reported.

AGRICULTURAL BOTANY.

Report of the botanist, G. E. STONE and N. F. MONAHAN (*Massachusetts Sta. Rpt. 1905, pp. 115-145*).—Notes are given on a number of diseases that have been under observation. The long period of dry weather rendered many plants free from fungus diseases, but, on the other hand, the conditions were favorable for the outbreak of others. The downy mildew of the tomato, potato rot, and cucumber and melon blight are briefly noted, after which the effect of sun scald, leaf scorch of conifers and other evergreens, winterkilling, etc., are described.

An account is given of some investigations carried on to determine the relation between soil aeration and germination and growth. In these experiments air was forced through the soil, and lettuce seed, which is quite susceptible to aeration, was planted in the different boxes. From the results tabulated it is shown that a considerably larger proportion of the seed germinated in the aerated box than in the unaerated one.

A comparison of sterilized loam and sterilized subsoil was made, 8 pots being used, 4 containing loam and 4 subsoil; of these 2 each of the loam and subsoil were sterilized, and the remaining pots were left unsterilized as checks. After sterilization soy beans were planted, and in the sterilized loam there was an increase of 14 per cent in the germinations, while in the sterilized subsoil there was a loss of 57.7 per cent. No explanation of this phenomenon is offered, but it shows that extreme precautions are necessary in drawing deductions from experiments in which the soil is sterilized.

The influence of soil sterilization on the germination of old seed was tested, the object being to ascertain the degree of acceleration which would result from seed planted in sterilized soil. Seventeen lots of seed were planted in sterilized soil and an equal number in unsterilized soil. The germinations were counted, and showed a positive gain in the germination of seed sown in sterilized soil. Marked differences were obtained from different kinds of seed, tomatoes responding but little, if any, to this method of treatment. The cause of the variation in different species is unknown.

In attempting to ascertain the causes underlying the effects of sterilized soil on seed germination mentioned above, the authors carried on a series of experiments in which soil decoctions were used to water the seed. The results indicate that the acceleration and increased germinating capacity of sterilized soil may have a chemical explanation. Undoubtedly the driving out of the gases and the subsequent absorption and renewal of fresh oxygen in sterilizing practices act beneficially to the soil and induce the seed to germinate more quickly. Sterilized subsoil, or soil lacking in humus, has the same effect on germination as sterilized loam rich in organic matter, but it inhibits growth to a large extent, differing markedly in this respect. It appears from these experiments that a considerable amount of humus is necessary in soils in order that they may be materially benefited by sterilization.

The results of germination experiments to test the relative value of light and heavy seeds are given. The general conclusion is drawn that with many kinds of garden seed it is best to separate the seed and discard all but the large, well-developed, mature, and heavy seed.

The occurrence of asparagus rust during the season is discussed, this disease having been particularly troublesome in many parts of Massachusetts as the result of the extremely dry summer. Cultural methods are said to have given beneficial results in keeping this disease in check, and weekly cultivation combined with judicious fertilization has proved very satisfactory. The authors believe that the practice of burning the old asparagus brush in the fall is, by destroying a large number of teleutospores, an efficient method of control.

Spraying with Bordeaux mixture has not proved satisfactory and this method of control is no longer recommended.

An account is given of the treatment of the college pond with copper sulphate for the destruction of algae which had become very troublesome in it. Treatment of the pond with 1 part of copper sulphate to 4,000,000 parts of water showed that after 24 hours there was a slight decrease in *Anabana flos-aqua*, the most common alga, and in 2 or 3 days it had practically disappeared. Spirogyra, desmids, and diatoms appeared unaffected by the treatment, and the animal life showed no ill effects, so far as the authors could observe. From examinations made of the bacterial content of the water it was found that there was a rapid decrease for the first few days after treatment, after which there was a slight increase, but that the number of bacteria per cubic centimeter of water never reached the original proportion.

A comparison of the numbers of bacteria in sterilized and unsterilized soils, A. V. OSMUN (*Massachusetts Sta. Rpt. 1905, pp. 146-148*).—A study was made of sterilized soil to determine the effects of sterilization on the bacterial flora. The stimulating effect of soil sterilization on plant growth had suggested a similar effect on the bacterial content of the soil.

To investigate this subject two boxes of equal size were filled with soil, one being treated for half an hour with steam and the other left untreated. One week after sterilization samples were taken from each box and the bacterial content determined. At the first examination a decided decrease was noted in the bacterial content of the sterilized soil as compared with the unsterilized, but after an interval of 2 weeks the number of bacteria in the sterilized soil had increased to almost double the number in the unsterilized soil and continued to be greater as long as the investigation was carried on.

From the results obtained in this experiment and from tests of other soils, both sterilized and unsterilized, the author concludes that steam treatment of soils stimulates bacterial development in them.

Notes on the formation of albuminoid substances in plants, L. MONTE-MARTINI (*Atti Ist. Bot. Univ. Pavia, 2. ser., 10 (1905), p. 20; abs. in Bot. Centbl., 102 (1906), No. 28, pp. 35, 36*).—From a review of the literature it is shown that different investigators have obtained contradictory results regarding the action of light on the formation of nitrogenous material in plants.

The author carried on a series of experiments, a preliminary report of which is given. From his results it is shown that in the germination of beans and maize light exerts a very different effect, depending on the external and internal conditions under which it acts. The results of the experiments are to be given in detail at some future time.

The stimulation of the nutrition of plants, II. MICHEELS (*Rev. Hort. Belge, 32 (1906), No. 2, pp. 29-33; abs. in Bot. Centbl., 102 (1906), No. 30, pp. 90, 91*).—The author calls attention to the diverse conclusions of various investigators relative to the effects of stimulants on the nutrition of plants, some claiming that the addition of mineral fertilizers to the soil does not modify the mineral composition of the plants, but only stimulates their growth and the production of organic matter, while other investigators claim that certain mineral salts have a direct stimulating effect.

The author, in connection with a physicist, investigated the effect of various colloidal substances, and carried on experiments with barley, peas, buckwheat, and oats, which show that colloidal solutions have a direct stimulating effect and that in some cases they play the rôle of diastases. This appears to open up a new line of investigation on the nutrition of plants.

The synthesis and breaking down of organic nitrogen in plants, E. SCHULZE (*Landw. Jahrb.*, 35 (1906), No. 4, pp. 621-666).—A critical review is given of the literature relating to the subject of nitrogenous metabolism in plants with special reference to protein, asparagin, glutamin, ricinin, lecithin, etc. The author states that no attempt is made to include all the literature, but only such as appears necessary to give an adequate knowledge of the present status of the subject.

The formation and physiological use of pentosans in plants, G. A. CALABRESI (*Staz. Sper. Agr. Ital.*, 39 (1906), No. 1-2, pp. 69-93).—An investigation of the occurrence of pentosans in plants was carried on, in which a considerable number of plants were studied.

The literature relating to the occurrence of pentosans in plants is reviewed, and after describing his experiments, the author summarizes his own investigations, stating that the observations of de Chalmot (*E. S. R.*, 5, p. 1103) regarding the presence of pentosans in seeds germinated in the dark are also true for many plants in their adult stages of growth. The pentosans seem to be produced by the transformation of other substances which are formed early in the life of the plant, and with the gradual increase in the dry material of the plant they appear to diminish. The percentage of pentosans in a given plant does not depend on the external development and weight of the green plant, but under like conditions the age of the plant determines this question. The percentage of cellulose seems to have a definite relation to the amount of pentosans, but it has not yet been demonstrated that this quantitative proportion signifies any generic relationship. Among the cereals investigated, the author found that those stems which are most resistant to the effects of storms are usually richest in pentosans. In beet roots there appears to be a definite relation between the quantity of saccharine matter present and that of pentosans, the proportion of the former being less than that of the latter. In general, the greatest quantity of pentosans will be found in plants that contain the least amount of other nutritive substances.

On the relation between calcium salts and the assimilation of nitrate nitrogen, W. W. YERMAKOV (*Zhur. Opušn. Agron. (Russ. Jour. Expt. Landw.)*, 6 (1905), p. 431; *abs. in Chem. Ztg.*, 30 (1906), No. 22, *Repert.* No. 6, p. 83).—On the basis of experiments with plants and from theoretical considerations, the author concludes that calcium is necessary to the assimilation of nitrate nitrogen in plants. The explanation of this is that the nitric acid produced in plants acts on glucose to produce ammonia, which is utilized in the formation of proteid compounds, and oxalic acid, which is precipitated by lime and thus prevented from interfering with the continuation of the process.

Tubercles on legumes with and without cultures, J. L. SHELDON (*West Virginia Sta. Bul.* 105, pp. 319-334).—The results of field, greenhouse, and laboratory tests with different forms of cultures for the inoculation of legumes are reported. These were begun in 1904 with cultures of bacteria from this Department and a commercial preparation, comparison being made with the same species of legumes grown without inoculation.

In some of the experiments the author obtained results that seemed to indicate that the germination of the seed was interfered with in some way by the treatment, and an examination of the roots of both inoculated and uninoculated plants seemed to indicate that while the use of cultures is not to be condemned they are not needed in the majority of West Virginia soils. In some cases the author attributes the failure to obtain a stand and a profitable crop of such legumes as alfalfa, clovers, and cowpeas to imperfect soil conditions and the abundance of weeds rather than a lack of bacteria. Tables are given showing the gain or loss of different crops attributed to inoculation.

FIELD CROPS.

Report on agricultural investigations in Alaska, 1905 [Field crops], C. C. GEORGESON (*U. S. Dept. Agr., Office Expt. Stas. Bul. 169, pp. 39-51, 56-58, 61-63, pls. 3*).—Earlier work with field crops at the Alaska Stations has been previously reported (*E. S. R., 17, p. 349*). The work at the Sitka station is now devoted chiefly to horticulture.

Work at the Copper Center Station.—It has been demonstrated at this station that owing to the early frosts in August grain growing is not very successful, but that under usual conditions any amount of rough feed can be produced. It was found that new ground fertilized with guano at the rate of 500 to 600 lbs. per acre produced from 50 to 90 per cent better crops than when no fertilizer was used. Each variety of the various grains tested was grown on several tracts. On tracts A, B, and C half of each plat was fertilized at the time of seeding with guano at the rate of 500 lbs. per acre. Tracts A and C were seeded with a small hand drill. Tract B was seeded in open drills by hand and covered with the hand rake. Tract D was seeded with a horse drill. Frost on August 14 seriously injured the crops.

A crop of winter wheat sown August 3, 1904, came through the winter fairly well, and the grain was in the dough and beginning to harden when injured by the frost in August. It is believed that some of the grains will grow. Romanow spring wheat sown May 9 matured no seed. Saskatchewan fife sown May 10 was sufficiently matured for good hay by August 30, and cured very quickly when cut. Notes on a number of other varieties of wheat are given, but in every case these were injured by frost. Ladoga and Harold were the furthest advanced when the first killing frost came, and part of the grain secured was matured sufficiently to grow. These 2 varieties were followed in degree of maturity by Ebert, Pumper, Stanley, Early Riga, and Roumanian.

Silver hull buckwheat from home-grown seed from the crop of 1903 made a good growth, but was killed to the ground by frost August 14, when some of the seed was nearly matured.

Excelsior winter rye sown July 16 had the grain well filled and was in the dough on July 28. It was not matured when injured by frost, when the crop was cut for seed. True Stock spring rye on fertilized ground grew from 40 to 44 in. high, and yielded fully two-thirds more forage than oats under like conditions.

Champion barley on tract A, sown May 11, was in the hardening stage at the time of the first frost and was thrashed for seed. On tracts B and C the crop was spoiled by frost. Hanna 2-rowed barley on tract B, seeded broadcast May 23 on the ground, had matured sufficiently for good hay by August 22. Lapland was almost ripe on August 14, but the frost shriveled the grain to some extent. When the first killing frost came, August 14, Champion was the furthest advanced, being closely followed by Chevalier, Odessa, Black Hulless, Manchuria, Mansbury, Hanna No. 9133, and Primus No. 10586.

Finnish black oats on tract B, from Sitka Experiment Station seed, were little damaged by the frost, and the crop was saved for seed. On tract A, which was sown May 12, there was no visible injury from frost. Of the different varieties of oats grown Burt Extra Early ripened several days before any other variety and was thrashed before frost. Finnish, Swedish Select, Sixty-day, Improved Ligowo, and Tartar King ripened about together, and the early seedlings showed no injury from the frost of August 14.

The grasses under test were in their third season of growth, but owing to a dry year poor results were secured. Red, white, and alsike clover, sown in 1903

and 1904, were winterkilled, and the plats reseeded this year made very little growth. The same was true of perennial rye grass.

Work at the Rampart Station.—The crops at this station were grown on virgin soil, without fertilizer. On the spots where stumps had been burnt a fine growth was secured, but elsewhere the stand was thin and the straw short. Maunshury barley, from Sitka-grown seed, sown May 19, was harvested September 6. This variety produced well-filled heads of good length. Rampart-grown seed gave practically the same result. The Saskatchewan life spring wheat, from Canadian seed, did not mature, and Velvet Chaff Blue Stem only ripened partially. Spring rye, sown May 19, began to head 47 days later, but it filled so slowly that it did not fully mature. Russian buckwheat was one of the few crops killed by frost August 19. Amber, Excelsior, and Giant French winter rye, sown August 17, matured and were harvested on September 5. Kharkov winter wheat almost all winterkilled.

Work at the Kenai Station.—Oats sown May 30 and 31 stood 36 to 40 in. high on August 15, with 75 per cent of the plants headed. September 1 they were 48 to 60 in. high, but some of the grain was injured by frost. Hanna 2-rowed barley, sown May 26, was in the milk and dough stage when injured by frost, and buckwheat, sown the same day, had ripened a small percentage of its grain when killed by frost August 26. Grass seed was sown May 25, and the following heights on September 1 are recorded from different species: Tall fescue, 18 in.; timothy, 18 in.; orchard grass, 12 in.; Italian rye grass, 10 in., and a mixture of the grasses planted this season, 10 in. Seeds of wild rye, wild barley, and *Calamagrostis tangsdorffii*, all native species, were much slower in germinating than the imported seed.

Report on agricultural investigations in Hawaii, 1905 [Field crops], J. G. SMITH (*U. S. Dept. Agr., Office Expt. Stas. Bul. 170, pp. 13-22, 23, 24, pl. 1*).—A cooperative tobacco experiment is in progress for the purpose of demonstrating the practicability of growing the best grades of cigar tobacco in Hawaii. In connection with a brief report on the experiments some of the Hawaii tobacco soils are described, the advantages of the climate for tobacco growing pointed out, and a general outline of the cultural processes followed is given.

In 1904, at Hamakua, the following varieties were grown under cloth: Sumatra, Florida, and Long Stem; Cuban, Florida, and Vuelta Abajo; Connecticut Broad Leaf and Seed Leaf; Zimmer Spanish; Virginia Dark Leaf; White Burley, and Japanese. This year's work demonstrated that tobacco under cloth was not successful in Hawaii, at least in regions of high rainfall. Brief notes on the behavior of each variety are given. The quality of the leaf of some of the varieties was pronounced excellent by experts and manufacturers.

The results of 1905 indicated that wrapper tobacco of fine texture and body and filler leaf of mild flavor and of good burning qualities are commercial possibilities. This season the crop was grown in the open, the only protection being forest on all sides of the plat. While the quality of the tobacco produced was good, the shade was darker than the market demands. About 20 per cent of the crop of Sumatra was of excellent quality as regards texture and body, but only about 10 per cent showed desirable shades of color. This portion of the crop was valued at from \$2 to \$4.50 per pound. The yield was at the rate of about 1,000 lbs. per acre. The portion of the crop unsuited for wrappers commands a price of only about 10 cts. per pound. The leaf of the Cuban tobacco not suitable for wrappers sells at prices ranging from 15 to 40 or 50 cts. per pound. The yield of the Cuban leaf ranges from 450 to 600 pounds per acre, and fully 25 per cent of this season's crop would have been suitable for wrapper leaf if the colors had been lighter. It is estimated that if a grower

produced tobacco on his own land and with his own labor the green leaf could be produced at the cost of about 2 to 2½ cts. per pound.

General notes on the culture of cassava in Hawaii are given and its value for Hawaiian conditions is indicated.

Report on agricultural investigations in Porto Rico, 1905 [Field crops], D. W. MAY (*U. S. Dept. Agr., Office Expt. Stas. Bul. 171, pp. 1-17, pls. 2*).—General notes on the agricultural conditions of Porto Rico are presented and the conditions and prospects of the culture of sugar cane, tobacco, cotton, corn, rice, potatoes, and forage crops are discussed.

Experiments with cotton at the station indicate that sea-island cotton is the most profitable for Porto Rico. Egyptian cottons made a very rank growth, but the production was not very satisfactory, probably due to the excessive rainfall. The fertilizer experiments with cotton show that the three elements of plant food were needed, but more especially potash and phosphoric acid. It is estimated that from 6,000 to 7,000 acres were planted with sea-island cotton during the season. The two principal insect enemies of this crop at the present time are the cotton caterpillar (*Alabama argillacea*) and the cotton stainer (*Dysdercus suturellus*).

The results from seed corn from the States have not been promising. The only serious insect pest of the corn plant is the cotton bollworm (*Heliothis obsoleta*).

Of 5 varieties of potatoes from northern-grown seed the best results were obtained from Bliss Triumph and Early Rose. Some of the potatoes produced were shipped to San Juan and New York, and the indications are that under proper conditions potatoes may be grown commercially with success. Heavy fertilization and frequent spraying with Bordeaux mixture are recommended for successful potato culture.

Of the different forage crops grown the cowpea proved the most promising. Beggar weed made a fair growth, but did not reach the height it does on the light sandy soils of Florida. Velvet beans were not equal to the cowpea for a quick-growing crop. On properly drained and inoculated soil alfalfa made a promising showing. So far the clovers have not done well, and lupines and vetches have also failed to make satisfactory growth. The sugar beet was found subject to blight in the later stages of its growth. Turnips and kale in experimental plats did very well. Improved varieties of peanuts from the States gave good results at the station, while horse beans were practically a failure. Experiments with fiber crops are in progress, and the insular government has made provision for growing sisal on a commercial footing.

Report of the agriculturists, W. P. BROOKS, F. R. CHURCH, and S. B. HASKELL, (Massachusetts Sta. Rpt. 1905, pp. 15-13).—The lines of work were the same as those followed in recent years (*E. S. R., 17, p. 234*). The experiments this season included 244 field plats, 150 closed plats, and 245 pots in vegetation experiments.

Mixed oats and peas were grown this year in connection with comparative tests of different sources of nitrogen, and on the basis of yields secured the materials ranked as follows: Nitrate of soda, dried blood, sulphate of ammonia, and barnyard manure. Based on the increase of all the crops since the beginning of the experiments the relative rank was: Nitrate of soda 100, dried blood 68.72, sulphate of ammonia 60.78, barnyard manure 80.58.

High-grade sulphate of potash was superior to muriate for clover, for rhubarb, and for blackberries. The different potash salts used as fertilizers for soy beans this season ranked as follows: Carbonate, high-grade sulphate, silicate, nitrate, muriate, low-grade sulphate, and kainit. The poorest results were obtained with kainit, the crop being much lower on the kainit plats than

on those which had received no potash for the past 8 years. In the experiments with a fertilizer mixture rich in potash and a special corn fertilizer the yields were practically equal, but the cost of the fertilizers was lower when the fertilizer rich in potash was used. The crop of this year was mixed hay.

In the comparison of a moderate application of barnyard manure alone with a smaller application of manure in combination with 160 lbs. of high-grade sulphate of potash per acre, the larger average yield was produced with the manure and the potash, and this combination also costs \$6.40 less per acre than the larger quantity of manure alone. Mixed hay was also grown in connection with this test.

The spring application of barnyard manure gave the better yield in all cases, but the difference was not sufficient to cover the larger cost of the extra handling. There was little or no wash over the surface during the winter.

On the grass lands receiving different fertilizer treatment in rotation the average yield of hay was at the rate of 4,840 lbs. per acre for all 3 systems of manuring. The average yield in this test from 1893 to 1905, inclusive, was 6,479 lbs. An application of nitrate of soda, after harvesting the first crop of grass, gave but a relatively small increase in yield, but, in one instance, where applied at the rate of 150 lbs. per acre an increase of nearly 1 ton of rowen, or considerably more than sufficient to pay the cost of the fertilizer was obtained. The results in determining the relative value for garden crops with fertilizers supplying respectively nitrogen and potash, when used with manure, show that on the basis of total crops produced the standing of the different nitrogen fertilizers is, for the early crops, nitrate of soda 100, dried blood 95.67, sulphate of ammonia 63.08, and for late crops nitrate of soda 100, dried blood 98.77, sulphate of ammonia 79.52. For 15 years the relative standing of the fertilizers supplying potash is, for early crops, sulphate of potash 100, muriate of potash 94.66, and for late crops sulphate of potash 97.09, and muriate of potash 100.

A large number of experiments during the past 8 or 10 years indicate the doubtfulness of successful alfalfa growing in Massachusetts.

Illustrations of the influence of experiment station work on culture of field crops, J. I. SCHULTE (*U. S. Dept. Agr. Yearbook 1905, pp. 407-422, fig. 1*).—Specific instances are given of the improvements brought about in methods of farming and in the use of improved varieties of crops through the influence of the experiment stations. Shallow culture of corn, more careful seed selection, varieties adapted to special districts and purposes, heavier yields of oats, better varieties of cotton, the control of potato diseases, better methods in fertilizing and sweating tobacco, the development of the sugar-beet industry, the distribution of new varieties of sugar cane, the introduction of new forage crops, etc., are among the more important matters discussed.

Experiments with grain and forage plants, 1905, R. A. MOORE and A. L. STONE (*Wisconsin Sta. Rpt. 1905, pp. 330-355, figs. 5*).—The variety tests with grain and forage plants for the season were mainly conducted as in previous years. The results are briefly discussed and the data secured are presented in tables.

The Oderbruck and Manshury barley were the most satisfactory varieties on trial. Oderbruck has now been grown for 7 years by the station, in comparison with 36 different varieties and improved by selection. In 1905 a yield of 58 bu. per acre, weighing 50 lbs. per measured bushel, was obtained, and on the average for the 7 years 53½ bu. per acre was secured. This variety has shown a protein content of 15 per cent. Maushury barley grown in 66 cooperative tests

gave an average yield of 38.6 bu. per acre, or 6.7 bu. more than other varieties on trial.

Of 18 varieties of oats, Swedish Select, White Bedford, American Banner, and Wisconsin Wonder showed the most desirable characteristics. Sixty-day oats, one of the newer varieties, ranked first this season, with a yield of 66.8 bu. per acre. The Swedish Select oats are well adapted for uplands and seem to do better on poorer grades of land than other varieties tried. Their great root development renders them resistant to droughts. When grown on low rich soils they are likely to lodge and to fail to fill out.

Two varieties of winter wheat, Minnesota No. 550 and Beleglona, yielded 31.5 and 33.6 bu. of grain and 3.05 and 2.27 tons of straw per acre, respectively.

Through a series of 5 years, early varieties of soy beans gave yields varying from 20 to 40 bu. of beans per acre. Planted and cut with corn soy beans made an excellent silage, but were unsatisfactory when used alone. The plants were observed to develop nodules on their roots without inoculation when grown continuously upon the same ground for 3 years. With inoculation nodules were developed the first year. On rich land the effect of inoculation was not apparent, but it was very noticeable on the poorer grades of soil.

Four acres of sandy and clay loam soil were spring-plowed and sown with alfalfa at the rate of 20 lbs. per acre April 27, 1904. Barley sown at the rate of 1 bu. per acre was used as a nurse crop. A top dressing of well-rotted manure was applied in the fall of 1904 and in 1905 crops were cut June 12, July 13, and September 1, from which a total yield of $3\frac{3}{4}$ tons per acre was secured. In cooperative tests in 1904, 87 of 120 experimenters secured good stands of alfalfa, the common American variety doing as well as the Turkestan. From the results thus far secured it is concluded that under proper conditions alfalfa may be grown in practically all counties of the State.

Cooperative experiments with medium red clover have been in progress with this Department. Twenty-four, including 2 foreign varieties, were under test. Russian U. S. No. 12169 was exceptionally fine and yielded at the rate of 16.32 tons per acre of green forage and 3.64 tons per acre of well-cured hay. Four $1\frac{1}{2}$ -acre plats of Russian and American red clover were compared with a 3-acre plat of common medium red clover in 1905. The yields from these different plats varied from 1.7 tons for the common medium red to 2.2 tons for Russian No. 2.

The corn-breeding work of the station is carried on for establishing earlier maturing qualities in some of the later heavy-yielding varieties of yellow dent corn. In the breeding experiments Wisconsin No. 8, originally the Minnesota No. 13, was used as the male parent, with 8 other varieties for the female parent. These varieties were planted in 1904 and the progeny was tested in 1905. The result secured with each selected ear is shown in a table. Striking variations in the manner of growth and bearing qualities of the different ears manifested themselves. In a cooperative test of growing Silver King corn, for the purpose of selecting progeny of high-yielding ears for further trial, the rows, each representing a single ear, showed a variation in total yield of from 14 to 97 bu. per acre of shelled corn and an average yield of $58\frac{1}{2}$ bu.

Fertilizer experiments were conducted with barley, sugar beets, oats, soy beans, and clover. Different combinations of commercial fertilizers were used. The beneficial effects were detected on the grain plats as soon as the plants appeared above ground. The clover showed no apparent difference between fertilized and unfertilized plats.

In treating barley with formaldehyde solutions for the eradication of smut, the general results indicated that solutions stronger than 1 pt. of formaldehyde to 20 gal. of water are likely to injure the germinating power of the grain,

especially when exposed to the solution for as long a time as 24 hours before sowing.

Wyoming forage plants and their chemical composition, H. G. KNIGHT, F. E. HEPNER, and A. NELSON (*Wyoming Sta. Bul. 70, pp. 75, pl. 1, figs. 31*).—The work here presented is in continuation of that reported in a previous bulletin (E. S. R., 17, p. 240).

The description and analyses of the following plants are recorded: Mountain wheat grass (*Agropyron violaceum*), rough hair grass (*Agrostis hyemalis*), Canada bent grass (*Calamagrostis canadensis*), marsh foxtail (*Alopecurus fulvus*), slough grass (*Beckmannia cruceiformis*), gramma grass (*Bouteloua oligostachya*), short awned brome grass (*Bromus marginatus*), Porter's brome grass (*B. porteri*), drop seed (*Sporobolus brevifolius*), reed meadow grass or manna (*Panicularia americana*), nerved manna grass (*P. nervata*), giant rye grass (*Elymus condensatus*), King's fescue (*Festuca kingii*), meadow barley or slender squirrel-tail (*Hordeum nodosum*), prairie June grass (*Koeleria cristata*), timothy (*Phleum pratense*), mountain timothy (*P. alpinum*), Nevada blue grass (*Poa nevadensis*), field sedge (*Carex mureida*), Liddon's sedge (*C. liddoni*), Nebraska sedge (*C. nebrascensis*), spike rush (*Elcocharis palustris*), long-styled rush (*Juncus longistylis*), thermopsis (*Thermopsis divaricarpa*).

Forage crops grown at Coast Land Experiment Station, W. D. GARRISON (*South Carolina Sta. Bul. 123, pp. 15*).—This bulletin gives the date of planting and harvesting and describes briefly the forage crops tested. The results are summarized in the following table:

Yields of forage crops at the Coast Land Experiment Station in 1905.

Crop.	Date of planting.	Date of harvesting.	No. of cuttings.	Yield per acre.	
				Green.	Dry.
Alfalfa		May 30-Sept. 4		Lbs.	Lbs.
Cat-tail millet		May 30-Sept. 28	4	12,196	2,905
Teosinte	Apr. 6	May 30-Sept. 28	6	94,424
Florida beggar weed	Apr. 17	June 6-Sept. 29	6	43,923
Berseem or Egyptian clover	Apr. 21	July 1-Sept. 28	4	23,147	4,630
Mangel wurzels	Mar. 22	June 3		8,512	1,836
Early amber cane and Florida beggar weed.	Mar. 25	July 31		20,790
Early amber cane and Iron cowpea....	July 18	Sept. 19		20,520	5,760
Early amber cane and Newman bean....	Mar. 25	June 23, Sept. 4	2	81,238	37,097
Crimson clover	do	June, Sept. 4	2	72,226	33,500
Rescue grass	Oct. 31	May 2		14,850	3,600
Wheat and hairy vetch	Oct. 24	Apr. 20-June 17	3	25,025	6,386
Hairy vetch	Oct. 31	May 13		16,329	7,732
Dwarf Essex rape	do	May 11		15,838	3,184
Barley	Nov. 2	May 1		11,161
Rye	Oct. 31	Mar. 15, Apr. 6	2	8,695
Wheat, in beds	Nov. 10	do	2	12,712
Wheat, planted on level	Oct. 24	Jan. 17-Apr. 19	3	16,120
	do	do	3	12,524

Several varieties of cowpeas were planted June 3, 6, and 21. The yields varied from 8 to 15.9 bu. per acre. Iron cowpeas planted in rows 3 ft. apart yielded from 2,395 to 4,882 lbs. of hay per acre. A plat sown broadcast June 22 and harvested September 28 gave a yield per acre of 14,163 lbs. of green substance and 2,535 lbs. of hay.

Farm practice with forage crops in Western Oregon and Western Washington, B. HUNTER (*U. S. Dept. Agr., Bur. Plant. Indus. Bul. 94, pp. 39, figs. 4*).—This bulletin describes the methods of growing and handling forage crops in the Pacific Northwest by farmers who have been most successful in this line of work. A description of the region is given and notes on haymaking, the silo, and the value of leguminous plants are also presented. The crops discussed have

an important place in the agriculture of the region, and the methods of seeding, culture, and fertilization described are based almost entirely upon the prevailing farm practice. Red clover, alsike clover, common vetch, pearl vetch, field peas, alfalfa, timothy, the rye grasses, orchard grass, meadow fescue, velvet grass, Indian corn, rape, thousand-headed kale, root crops, and soiling crops are the crops treated of. A brief note is also given on seeding timber burns and burnt slashings.

Diversified farming in the cotton belt, W. J. SPILLMAN ET AL. (*U. S. Dept. Agr. Yearbook 1905*, pp. 193-218, pls. 3).—A series of articles is presented with a view to pointing out lines along which further progress in the diversification of crops along the South Atlantic coast, in Alabama, Mississippi, Louisiana, Arkansas, and Northeastern Texas, and Texas as a whole, may be made. A special study was made of each one of the regions mentioned and a separate report for each section is given.

The South Atlantic coast region is divided into agricultural sections, according as the different localities vary in character and crop production, and the agricultural practices for each section are briefly noted.

The observations made in Alabama and Mississippi led to the conclusion that the depletion and the washing away of the soil on southern farms may be prevented by establishing a system of farming which would increase the organic content of the soil. It is suggested that this may be done either by a system of crop rotation involving the use of leguminous crops and green manures, or by feeding a large portion of the crops on the farm and returning them to the soil as animal manures.

In the discussion on Louisiana, Arkansas, and Northeastern Texas, implements commonly used in the South are shown and described. Brief notes on their use, including the terms commonly applied to the different tools and operations, are given.

Summary of press bulletins (*Oklahoma Sta. Rpt. 1905*, pp. 20-33, figs. 2).—The subject-matter contained in this summary is largely reprinted from other publications of the station. Only the more recent results are here noted.

In the experiment with Bermuda grass (*E. S. R.*, 17, p. 1062) a yield of 5,658 lbs. of cured hay per acre was secured in June, 1906. In September, 1905, less than 3 months after planting the ground with Bermuda grass sod 2,584 lbs. of hay was obtained, so that within less than a year 8,242 lbs. of hay was produced per acre.

Of different varieties of wheat tested Turkey red and Turkish red, believed to be the same, exceeded 25 bu. per acre in yield. Sibley New Golden, grown for several years on the college farm, stands first in average yield during a period of 5 years ending June 30, 1904. Some Northern varieties classed as spring wheats gave good results when sown in the fall in Oklahoma. The results during 3 years of pasturing wheat showed without variation that late spring pasturing is very detrimental to the crop. In 1905 a catch crop of soy beans was grown after wheat and a yield of 4.33 bu. of beans per acre was secured.

The business of seed and plant introduction and distribution, A. J. PIETERS (*U. S. Dept. Agr. Yearbook 1905*, pp. 291-306, pls. 3).—The history of seed and plant introduction and distribution by the Commissioner of Patents in former years and by this Department as his successor up to the present time is reviewed and the method of carrying on the work to-day is described. Estimates of the present annual value of some of the important crops introduced since the first appropriation in 1839 are presented. The crops and varieties included in this list are sorghum, Kafir corn, Durum wheat, Japanese Kinslu rice, Swedish select oats, Excelsior white Schonen oats, Chevalier barley, Fultz wheat, and the Washington navel orange.

Experiments on the germination of new harvested seed, C. EBERHART (*Fühling's Landw. Ztg.*, 55 (1906), No. 17, pp. 583-591).—Samples of rye and wheat of different degrees of maturity were germinated by different methods, and the author concludes that germination in sand or between blotting papers is to be preferred to other methods.

Forcing the point of a pin into the smaller end of each grain had the effect of increasing the percentage of germination. Soaking the seed in water also increased the number of kernels which germinated. Both these treatments were unable to increase the percentage of germination and the rapidity of growth in wheat slightly immature. Treating the seed with ether had a favorable effect on its germination.

In general it was found that the germination of new harvested seed is governed by its degree of maturity. A sample of dead ripe rye showed a germination immediately upon harvesting, which the same grain, harvested in the milk stage, did not show until it had been stored for 40 days.

The effect of inbreeding in plants, A. D. SHAMEL (*U. S. Dept. Agr. Year-book 1905*, pp. 377-392, pls. 3, fig. 1, dgm. 1).—This article defines the term inbreeding and discusses the use of inbreeding in the improvement of animals, the different degrees of inbreeding in plants, and its effect on their vegetative vigor and fertility.

The beneficial effects of inbreeding in tobacco and the detrimental effects of inbreeding in corn are discussed. It is stated that inbreeding in tobacco is an effective means of maintaining desirable characteristics in the established varieties, while cross-fertilization within the varieties reduces uniformity and decreases vigor. A method of corn breeding to avoid inbreeding is described and illustrated. The author inclines to the belief "that the improvement of our crops can be most rapidly effected with permanently beneficial results by following the practice of inbreeding, or crossing, to the degree in which these methods of fertilization are found to exist naturally in the kind of plant under consideration."

The breeding of cereals by means of artificial crossing, E. TSCHERMAK (*Ztschr. Landw. Versuchsiv. Österr.*, 9 (1906), No. 6, pp. 699-743, pls. 2).—The author's work and its results are described at some length. The following crosses are enumerated as obtained in addition to those of wheat and rye: *Secale cereale* × *S. montanum*, *Aegilops ovata* × *S. montanum*, *A. ovata* × *S. cereale*, *Hordeum distichum* × *H. spontaneum*, *H. tetrastichum* × *H. spontaneum*, *H. trifurcatum* × *H. spontaneum*, *A. ovata* × *Triticum vulgare*, and *Hordeum sp.*, with *Elymus europaeus*.

In crossing rye, xenia, with reference to color of seed, was observed in several cases. An increasing tendency to vary in the two cross forms seemed to favor the appearance of xenia in the crosses secured, contrary to the opinion of certain investigators. When species of rye with different types of heads were crossed, the female parent was neither alone nor most prominent in exerting its influence on the product and its progeny. Natural crosses resulted where different species of rye were grown in alternate rows. In about one-half of the plants of the first generation of rye crosses the type of head and form of seed of the male parent was prevalent, while in the other half the same characters of the female parent predominated. In the second generation the individuals split up into groups, showing the type of head of either the one parent or the other, or of both together. One-fourth of the number of individuals showed the spike characters of the female parent, one-fourth those of the male parent, and one-half were intermediate.

Crosses of winter and spring varieties of rye, when grown as spring varieties, show a medium period of growth, and spring rye as the prevailing type in the

first generation. In the second generation the proportion of individuals of the spring type to those of the winter form, at the time of heading, was as 2.5:1, while in the third generation the proportion raised to 3.4:1. Winter culture of the first generation reduced the spring form to the proportion of 1.34:1, and this influence was still noticeable in the third generation. Summer culture of the second generation increased the proportion of the spring type to more than 3:1, but winter culture of the second generation reversed the proportion to 1:9.49.

The author concludes that not only morphological, but also adaptive characters are capable of showing transmission according to Mendel's law. He also found that the cultivated and wild forms of the cereals cross readily, and that the tribe *Hordeae* is especially disposed to cross breeding.

The feeding value of soiling crops at different stages of growth, H. VON FEILITZEN (*Svenska Mosskulturför. Tidskr.*, 20 (1906), No. 1, pp. 72-77).—A mixture of field peas, oats, and barley was grown on well decomposed marsh soil, and three cuttings were made, the first at the beginning of bloom and the second and third 10 and 20 days later, respectively. The largest yields of green forage, protein, carbohydrates, and other food ingredients were obtained in the last cutting, although the percentage content of the different constituents was highest in the first cutting. It is recommended to cut leguminous soiling crops when they have reached full bloom, as at this period the yields of both dry matter and nutrients are much higher than at earlier stages.—F. W. WOLL.

Alfalfa as a forage crop of Pennsylvania, G. C. WATSON (*Pennsylvania Sta. Rpt. 1905*, pp. 74-86).—The culture and fertilizer tests with alfalfa at the station for a series of years are summarized.

In the experience of the station alfalfa grew in a compact, gravelly soil with good drainage quite as well as in a loose loam. Heavy applications of phosphoric acid and potash were very effective in improving the growth of the crop, but 5 tons of barnyard manure per acre gave better results than the phosphoric acid and potash contained in 500 lbs. of a good brand of commercial fertilizer. Turkestan alfalfa did not appear as valuable as the common alfalfa. It is stated that fall-seeded alfalfa on dry land will withstand severe winters in Pennsylvania better than the common red clover. Where alfalfa grew vigorously from the start nodules appeared on the roots, but where the growth was weak and slow few plants were provided with them. Lime was in no case applied to advantage. In several instances alfalfa withstood the first winter, but was completely killed out during the second.

Inoculation experiments with alfalfa and soy beans, H. L. RUSSELL and R. A. MOORE (*Wisconsin Sta. Rpt. 1905*, pp. 242-261, pl. 1, figs. 6).—In the experiments reported the seed was first disinfected and then inoculation was brought about by the use of soil from previously cultivated alfalfa and soy bean plats and by the use of bacterial cultures. The tests were made under greenhouse and field conditions.

Field peas were also included in a part of the tests. The work was carried on for 2 seasons and the results seemed to warrant the conclusion that the necessary nodule-producing organism for the field pea is sufficiently abundant in the soils tested to make inoculation unnecessary. With alfalfa the inoculation with soil emulsions or soil scattered broadcast over the plats was more effective than the use of bacterial cultures. Soil from sweet clover fields or emulsion made from the sweet clover nodules was effectively used for the inoculation of alfalfa. The use of bacterial cultures had no effect on the soy bean, while seed infected with soil from an old soy bean field formed numerous nodules.

The improvement of corn in Pennsylvania, D. C. WING (*Penn. Dept. Agr. Bul. 133, pp. 76, figs. 18*).—This bulletin is a general treatise on corn and its culture. Special attention is given to the improvement of the crop with the hope of producing better varieties and better yields in Pennsylvania. The results of experiment station work have been largely drawn upon in its compilation.

Eureka silage corn—its value for Massachusetts farmers, J. B. LINDSEY and P. H. SMITH (*Massachusetts Sta. Rpt. 1905, pp. 86-93*).—Eureka silage corn, a late dent variety, was compared with Sibley Pride of the North, a medium dent maturing at the station.

In 1903 and 1904 Eureka grew 11 to 13 ft. high and when cut September 15 the ears were very immature and the whole plant contained about 6 per cent more water, more ash and fiber, and less extract matter than Sibley Pride of the North. The field-cured fodder of Eureka contained 69 per cent of water and that of Pride of the North only 38 per cent. The green and dry fodder of Eureka were found to be 67 and 64 per cent digestible, respectively, while Pride of the North cut green was 71 per cent digestible. The Eureka produced 64 per cent of stalks and 7 per cent of ears and Pride of the North 47 per cent of stalks and 22 per cent of ears. The yields of green fodder were 20 and 13 tons per acre, respectively, for Eureka and Pride of the North, but in actual food material produced the 2 varieties were nearly equal.

Variety and distance tests of corn and cotton, B. W. KILGORE ET AL. (*Bul. N. C. Dept. Agr., 27 (1906), No. 2, pp. 64*).—A record is given of the year's work on the North Carolina agricultural department test farms.

The results of variety tests for the past 5 years show that Coker Prolific is a most substantial and reliable variety of corn and one of the best on the sandy loam soils of the eastern part of the State. This variety from home-grown seed ranked second in 1900, 1901, 1904, and first in 1902, 1903, and 1905 at the Edgecombe farm. The data obtained at the different farms with all the varieties varied considerably. Notes on the different varieties grown are given and the sources of the seed used are listed. As indicated by an average of 5 years' results corn on the Edgecombe farm should be planted 4 by 3 ft., and on the Iredell farm, as indicated by 3 years' results, 5 by 2 ft.

Russell Big Boll cotton, on an average for 6 years, has ranked first among a number of varieties according to value of total crop, being followed by Culpepper Improved and Peterkin Improved. The different varieties are noted, and the sources of the seed used in 1905 are listed. The distance experiments at the Edgecombe and Red Springs farms during the past 4 years favored a spacing of 3½ ft. by 16 in. for the Edgecombe section and of about 4 ft. by 60 in. at Red Springs, while a three years' test at Iredell farm showed best results from planting 4 ft. by 24 in.

Cotton experiments, C. L. NEWMAN (*South Carolina Sta. Bul. 120, pp. 19*).—A number of fertilizer and variety tests with cotton are reported.

In one series of fertilizer tests cow manure and stable manure, with and without phosphoric acid and potash, and cotton-seed meal and hulls, with and without phosphoric acid and potash, were compared. The fertilizing constituents, from a chemical standpoint, were the same in quantity in the different applications. The largest yield of seed and lint per acre, being 664 and 332 lbs., respectively, was secured on a plat receiving 2,900 lbs. of stable manure, 192 lbs. acid phosphate, and 99 lbs. kainit. The average yield of seed cotton from the 2 plats receiving cow manure was 427 lbs. per acre, and from the plats fertilized with cotton-seed meal and cotton-seed hulls 260 lbs. per acre, showing that the meal and hulls after having served their purpose as a cow feed and converted into a fertilizer produced an increase in yield of 64 per cent over their direct application to the soil.

In another series of tests, comparing cow manure with compost, the quantities applied being based on the chemical analyses, the best yields amounting to 666.6 lbs. of seed and 333.3 lbs. of lint per acre, were secured from the use of 2,640 lbs. of compost per acre. This plat gave 82 lbs. more lint per acre than a plat which had received 5,428 lbs. of cow manure and 272 lbs. of acid phosphate.

In a third series of experiments, with the use of commercial fertilizers alone and in combination, an application of 1,360 lbs. of acid phosphate and 320 lbs. nitrate of soda per acre stood first in yield, with 754.7 lbs. of seed and 377.3 lbs. of lint per acre. This plat also ranked first in early maturity, 94 per cent of the crop being gathered by September 28. The effect of acid phosphate in hastening maturity was noticed in the results secured. A home mixture, applied at the rate of 595 lbs. per acre, containing 1.6 per cent of phosphoric acid, 0.64 per cent of potash, and 0.54 per cent of ammonia less than Peruvian guano, gave an average of 43.8 lbs. of seed cotton more per acre than the guano, which was given at the rate of 500 lbs. per acre.

The results with a number of varieties of cotton compared by the station during a series of years are compiled and presented in tables. It is shown that Texas Oak led in yield twice and ranked third once, Crossland stood third once, Bates' Improved Prolific ranked first once and second once, Doughtey's Long Staple and Jackson Limbless each stood second once. Peerless ranked second and third once, and Drake Cluster and Texas Burr were each third once.

The Aldrich system of growing cotton and corn, which consists in growing the cotton rows and corn rows alternately in pairs throughout the same field, was compared with 2 check plats, one in cotton and the other in corn. The cotton check produced 1,599.2 lbs. of seed cotton per acre, worth \$72.60, and the corn check 36 bu. of corn per acre, worth \$21.60, or a total of \$94.20 for 2 acres. The plat grown by the Aldrich system produced an aggregate value of \$13.58 less than the check plats, or \$6.79 less per acre.

The cultivation of maguey in the Philippine Islands, H. T. EDWARDS (*Philippine Bur. Agr. Farmers' Bul. 13, pp. 25, pls. 9*).—A general account is given of the history and distribution of maguey in the world and in the Philippine Islands. The plant is described, its climatic and cultural requirements noted, and its value and uses pointed out. In connection with directions for harvesting, a description of the extraction of the fiber and fiber-extracting machinery is presented.

Composition of soy beans, W. FREAR (*Pennsylvania Sta. Rpt. 1905, pp. 39, 40*).—The composition is reported of the grain of Cross Bred No. 6, Early Black, Ita San, and Early Green soy beans.

The conclusion is drawn from the data that for seed the Cross Bred No. 6 and the Early Black are the safer varieties in the more elevated and northern part of Pennsylvania, and that Ita San and Early Green, which are early enough for the southern and less elevated portions of the State, are preferable for that region on account of the size of the plants and their productiveness. None of these varieties gave a yield of 35 bu. per acre, which was secured by the Massachusetts Station from the Medium Early White variety.

Experiments with sugar beets, season 1905, F. W. WOLL, R. A. MOORE, and A. L. STONE (*Wisconsin Sta. Rpt. 1905, pp. 356-362, dgm. 1*).—Variety, fertilizer, and culture tests were made.

In the variety test the highest yield, 15,631 lbs. of beets per acre, was secured from Breustedt Kleinwanzleben. The yields of beets and of sugar from Breustedt Kleinwanzleben, Schlanstedt Kleinwanzleben, and Heine Kleinwanzleben were above the average for the entire field. The sugar content of the beets ranged from 16.4 per cent in Hoerning to 17.7 per cent in Schaefer. The use of a complete fertilizer in growing sugar beets showed a marked improvement

both in the yield and the quality of the beets produced. The yield of beets was increased by 41.9 per cent and the yield of sugar by 17.3 per cent over the check plots. An acre of sugar beets grown for factory purposes yielded 23,065 lbs. of beets, or about 3,863 lbs. of sugar per acre. The sugar content for the entire field was 16.75 per cent and the purity 88.7 per cent.

Dark fire-cured tobacco of Virginia and the possibilities for its improvement, G. T. MCNESS and E. H. MATHEWSON (*U. S. Depl. Agr. Yearbook 1905, pp. 219-230, pls. 4, fig. 1*).—An article dealing solely with the dark tobacco of Virginia and treating expressly of the conditions existing in the district where this crop is produced.

The history of tobacco culture in the State is briefly reviewed, the types of leaf described, the common methods of cultivation, curing, and marketing discussed, and improvements in the different lines suggested. Notes are also given on the selection of soils, the making of seed beds, and the use of fertilizers.

In 1904 the Bureau of Soils began a series of experiments in Appomattox County with the object of determining by practical commercial tests what may be accomplished in these older tobacco-growing sections. An acre of land was fertilized after the usual farmer's method with 400 lbs. of fertilizer, costing \$5 an acre, and furnishing 12 lbs. of ammonia, 36 lbs. of phosphoric acid, 12 lbs. of potash. A second acre plot was fertilized with 850 lbs. of home-mixed fertilizer, costing \$16.44, and containing 73½ lbs. of ammonia, 57 lbs. of phosphoric acid, and 75 lbs. of potash, and a third acre plot received 1,700 lbs. of home-mixed fertilizer, costing \$32.30, and giving 153 lbs. of ammonia, 106 lbs. of phosphoric acid, and 125 lbs. of potash. The acre fertilized after the usual farmer's method yielded 673 lbs. of tobacco, which sold for \$45.50 gross, or an average of 6¼ cts. a pound. The second acre plot produced 883 lbs., selling for \$81.09, or an average of 9¼ cts. a pound, and the third acre plot yielded 1,334 lbs., which sold for \$111.29, or 8½ cts. a pound. To keep the product of the plots uniform the number of plants set per acre was 4,200, 5,000, and 6,000, respectively, and the net profit mentioned in the order given was \$5, \$21, and \$29.

The composition of turnips and swedes, J. HENDRICK (*Trans. Highland and Agr. Soc. Scot., 5, ser., 18 (1906), pp. 281-296, figs. 2*).—The work in Great Britain during recent years on the composition of turnips and swedes with a view to their improvement is summarized.

It was found that the upper half of the turnip and the outer portion contained a higher percentage of dry matter than the lower half and the inner portion. The determinations were made on sound and hard roots and the results are considered as probably not holding with dry roots, consisting largely of soft, spongy tissue. It is believed that by selection the composition of root crops may be improved.

Winter wheat, A. T. WIANCKO and M. L. FISHER (*Indiana Sta. Bul. 114, pp. 291-308*).—This bulletin summarizes the results secured with the varieties of winter wheat grown by the station since 1900.

In comparing the varieties Michigan Amber of home production was taken as the standard, the average yield for this variety for 6 years being 30.5 bu. per acre. Among the varieties seeming most promising or reliable at present are mentioned Rudy, Mealy, Tennessee White Fultz, Winter King, and Farmer's Friend. Dawson Golden Chaff and Gold Coin also gave good yields. Tennessee White Fultz, Dawson Golden Chaff, and Gold Coin have shown themselves to be very hardy, strong in straw, and good yielders, but they are all white and rather soft wheats and are, therefore, not recommended for milling qualities. The Hungarian and Russian varieties, including Gluten, Gluten B 86, California, Kharkov, Beloglino, Turkish Red, Buda Pesth, and Ghirka Winter were all very hardy, more or less rust resistant, and of excellent milling quality, but

extremely weak in the straw. Of the varieties having a 5-year record, Tennessee White Fultz, Winter King, Red Cross, Gluten B 86, Beechwood Hybrid, and Buda Pesth ranked first in the order given and their yields exceeded the yield of the standard variety by 27 bu. for Tennessee White Fultz and by 9.4 bu. for Buda Pesth.

Notes on winter-wheat culture are given, the value of crop rotation, and the relative effects of fertilization in good and poor wheat seasons are pointed out. In rotation experiments, which have been in progress on the university farm for 18 years, the continuous grain-growing plats in 1906 gave an average of 20.6 bu. per acre, as compared with 26.6 bu. per acre for rotations with clover. A rotation of corn, oats, wheat, and clover gave an average return for the 3 last wheat crops of 21.1 bu. per acre, while a rotation of corn and wheat gave but 16.9 bu. In the fertilizer experiments it was observed that the beneficial effects were very much greater in the poor seasons than in the good seasons, and that the average gains produced were 5 bu., or 116 per cent greater.

The flinty condition of wheat, F. R. FERLE (*Fühling's Landw. Ztg.*, 55 (1906), No. 14, pp. 492-494).—Two samples of flinty wheat which had been brought from the vicinity of Algiers in 1898 and kept in ordinary glass bottles were sown in the spring of 1905. These samples showed a germination of about 30 per cent. In the crop produced by one of the samples the normally developed grains were all flinty, and in the other sample the degree of flintiness was even greater than in the original seed. The author points out that while a reduction of the vegetative period through the lack of moisture and with an excess of light and heat wheat has a tendency to become flinty, the greatest and most important factor in the production of flinty kernels is inherent in the variety and is transmitted. He further states that a variety of a flinty character will retain its flintiness for a long time, even if grown under conditions unfavorable for the production of flinty grain.

HORTICULTURE.

[**Horticultural investigations in Alaska**], C. C. GEORGESON (*U. S. Dept. Agr., Office Expt. Stas. Bul.* 169, pp. 27-39; 51-54; 58-60; 63-65; 66-91, pls. 2).—Notes are given on the results secured at the Alaska experiment stations located at Sitka, Copper Center, Rampart, and Kenai, in the culture of various vegetables, orchard and small fruits, and flowers. Large quantities of seed were distributed to all parts of the Territory, and the reports of many persons who planted these are incorporated.

Report of the horticulturist, H. C. HENRICKSEN (*U. S. Dept. Agr., Office Expt. Stas. Bul.* 171, pp. 23-41, pls. 2).—This is the report of the horticulturist of the Porto Rico Experiment Station for the year 1905. It gives a general outline of the work done at the station during the year with citrus fruits, pineapples, mangoes, rubber, vegetables, and about 50 miscellaneous tropical plants.

Report of the horticulturist, F. A. WAUGH (*Massachusetts Sta. Rpt.* 1905, pp. 47-49).—Further notes are given by the author on the behavior of the winter-injured peach trees receiving (1) no pruning; (2) moderate pruning; (3) severe heading back, and (4) cutting back to stubs or dehorning (*E. S. R.*, 17, p. 248).

The general conclusion of the preceding year, that moderate pruning is to be preferred for winter-injured peach trees, still stands, "though the severely pruned trees made a relatively better showing under the stress of a good crop of fruit." The results of the experiment, as a whole, indicate that when the wood has been injured by freezing peach trees should be moderately pruned, removing not more than one-third to one-half the previous year's growth.

"When only the fruit buds are killed, the wood being uninjured and the trees in good condition, prune severely, cutting back the annual growth to two or three buds. It may be expedient to cut some branches back even into two or three year old wood."

Horticultural work (*Oklahoma Sta. Rpt. 1906, pp. 36-43*).—Notes are given on storing sweet potatoes, small fruits (E. S. R., 17, p. 664), and planting trees for posts, wood, etc.

The fundamental conditions for success in storing sweet potatoes are stated to be potatoes healthy and free from bruises and cuts, dry when stored, and kept dry while in storage, and the maintenance of temperature of the storage room between 50 and 65° F. One method of storing the potatoes is to keep the temperature of the storage room up to 90° for about a week as soon as the potatoes are stored, giving good ventilation. Where this process is not convenient the tubers should be given all the ventilation possible, so they can dry very rapidly for about 2 weeks.

The book of market gardening, R. L. CASTLE (*London and New York: John Lane Co., 1906, pp. 171, pls. 14, figs. 6, dgms. 5*).—This book discusses the business aspects of market gardening, dealing with the selection of land, labor questions, crops, preparation of produce for sale, grading, packing, marketing, cooperation, taxes, crop returns, values, etc. This is volume 27 in the series of Handbooks of Practical Gardening, edited by H. Roberts.

Excessive feeding as a factor in producing variation in tomatoes, E. P. SANDSTEN (*Wisconsin Sta. Rpt. 1905, pp. 300-314, figs. 11*).—An account is given of the variations obtained with the variety Spark's Earliana when the soil in the greenhouse bed in which they were grown was fertilized with nitrate of soda at the rate of 800 lbs., sulphate of potash 600 lbs., and desiccated bone 1,000 lbs. per acre.

The variations obtained by this excessive amount of fertilizers were as great as those commonly observed in different varieties. Many of the modifications in flower, foliage, and fruit are illustrated. Cuttings of the different plants, when rooted and transplanted to the open field, reproduced the variations observed in the greenhouse, and the writer is of the opinion that this method of producing variation in plants by excessive feeding may play a very prominent part in the securing of new varieties of plants.

Rhubarb culture, KUNATH (*Arb. Deut. Landw. Gesell., 1906, No. 117, pp. 12-44, figs. 5*).—An extensive account is given of rhubarb culture in Germany, with analyses with reference to food and fertilizer constituents and suggestions on the preparation of rhubarb for the table. Considerable data are given on the yields secured in experiments with different varieties of rhubarb and on the extent to which rhubarb is grown in different sections of Germany.

Rhubarb culture in England, B. SKALWEIT (*Arb. Deut. Landw. Gesell., 1906, No. 117, pp. 45-51*).—An account of the commercial culture of rhubarb in England, including directions for fertilizing rhubarb and a brief bibliography on the subject.

New fruit productions of the Department of Agriculture, H. J. WEBBER (*U. S. Dept. Agr. Yearbook 1905, pp. 275-290, pls. 7, fig. 1*).—Descriptions are given of a new citrange, 2 new limes, and 5 new pineapples originated under the author's direction.

The new citrange has been named Morton and is sweeter than either the Rusk or Willits, less bitter and almost seedless. It has resisted cold which has greatly injured other oranges, and it is believed that it can be grown from Tennessee and Arkansas southward and near the coast in Oregon and Washington. It will be chiefly useful as a breakfast fruit and for the preparation of citrangeade. The two new limes have been called Palmetto and Everglade.

Both are improvements over the lines usually grown in Florida. The varieties of pineapple have been called Miami, Seminole, Eden, Matthams, and Gale. Illustrated descriptions are given of each, with an account of its origin. All are remarkable for their superior flavor.

Promising new fruits, W. A. TAYLOR (*U. S. Dept. Agr. Yearbook 1905*, pp. 495-510, pls. 9).—Historical notes and illustrated descriptions are given of the Virginia Beauty and Carson apples; Crocker pear; Everbearing peach; Golden plum; Riley, Scioto, and Pringle Damson plums; Eulalia loquat, Hollis, Money-maker, Schley, and Success pecans, and Trapp avocado.

The relation of early maturity to hardiness in trees, R. A. EMERSON (*Nebraska Sta. Rpt. 1905*, pp. 101-110, figs. 13).—The author states "that resistance to cold in trees is due often almost wholly to the habit of early maturity rather than to constitutional hardiness." That early maturity and hardiness is in a large measure a matter of variety is brought out in a number of illustrations showing the difference of maturity in fall of different varieties of plums and apples. Young trees also grow longer in the fall than old trees, as a consequence of which the wood is less matured and the trees are more subject to injury from cold than older trees.

Data and illustrations are given for black walnut and honey locust trees, showing that trees grown from seed from a southern locality grow longer in the fall and enter the winter in a more sappy and green condition than the trees grown from seed obtained farther north. The hardiest trees of black walnut were grown from seed obtained from South Dakota. Natural late growing trees can be forced into early ripening by planting on high land instead of low ground and by the use of cover crops planted in midsummer, which dry out the ground enough to check growth of the trees and thus force them to ripen their wood before winter. By the use of cover crops late growing varieties were made to stop growth from a few weeks to 2 months earlier than similar trees in adjoining plats given late cultivation.

Conditions which affect the time of the annual flowering of fruit trees, E. P. SANDSTEN (*Wisconsin Sta. Bul. 137*, pp. 21).—The author made a study of the interrelation of climatic conditions to the time of flowering of a number of orchard fruits. Tabular data are given showing the blooming period for the years 1899-1905 of 26 varieties of plums and 25 of apples, and of the principal climatic features during each of these years.

It has been held that a definite number of heat or temperature units are required for a given species to come into bloom, and this has been termed its "physiological constant." The author shows that the relation between temperature and time of flowering of apples and plums in different years is too wide and variable to be used as a basis for calculating a physiological constant, especially if the spring temperature only is considered. In 1902 plums did not bloom until the average of 762 positive heat units had been received in the spring, while in 1901 they bloomed after receiving but 601 units. If, however, the positive temperature unit be reckoned from the preceding July—a period covering the entire development of the flower bud—instead of January, it is shown that the flower buds of 1901 received a total of 4,487 units, or 450 to 500 more than the flower buds of 1902 received.

A number of factors other than temperature were also found to influence the time of blooming. A heavy fruit crop retards the development of flower buds and delays blossoming. The distribution of the heat and rainfall during the growing season, soil conditions, and health of the trees are also factors. If these factors are eliminated "it seems reasonable, from the evidence presented [that], a physiological constant can be formulated from the climatic conditions during the 10 months preceding the time of flowering."

New opportunities in subtropical fruit growing, P. H. ROLES (*U. S. Dept. Agr. Yearbook 1905*, pp. 439-454, pls. 3, figs. 4).—The author discusses the uses and culture of the avocado, mango, sugar apple, ceriman, and guava.

The handling of fruit for transportation, G. H. POWELL (*U. S. Dept. Agr. Yearbook 1905*, pp. 349-362, pls. 4).—A discussion is given of the requirements of fresh fruits as regards harvesting, packing, cooling, and transportation to prevent molds, rots, and decay.

Owing to improvements in transportation facilities, fruits grown in California and the Southern States are shipped to Eastern and Northern markets in a fresh condition. Frequently large losses occur, due to shipping fruit too warm or in rough handling, both of which greatly favor the development of fungus diseases.

Mechanical injuries to the fruit may be caused by the puncture of insects, by the stem of one penetrating the other, finger-nail cuts, dropping the fruit on sharp surfaces, clipper cuts, etc. Some pickers may injure only 1 per cent of the fruit in gathering, while others may injure as much as 50 to 75 per cent. Any abrasion of the skin forms a lodging place for spores, which rapidly develop in warm, moist air, resulting in decay.

Factors which favor long keeping qualities are cold, dry, pure air, sound fruit, wrapping, cooling after it is picked, and shipping in comparatively small packages which cool quickly throughout. A free circulation of air should be maintained about the packages. Where possible fruits should be cooled before putting into refrigerating cars for shipment. Fruit allowed to stand until morning may be 20 to 40° cooler than when picked in the afternoon. The use of salt and ice in refrigerator cars will produce a lower temperature than the use of large cakes of ice alone.

It requires from 4 to 7 days for fruit in barrels held at 32° F. to cool down to a uniform temperature of 32° F. A longer time is required where the fruit is wrapped. The protection of the wrapped fruit, however, against bruising usually outweighs the disadvantage of slower cooling. While immediate cooling after picking and transportation in refrigerator cars will prevent the development of rots during transportation, such fruits if roughly handled, bruised, or cut in any way in harvesting will decay very promptly when offered on the market.

Small fruits in 1904, J. P. PILLSBURY (*Pennsylvania Sta. Rpt. 1905*, pp. 198-296).—Tables are given showing the usual annual data (E. S. R., 17, p. 254) relative to the date of flowering, ripening, rust resistance, vigor, yield, and size of a large number of strawberries grown in 1904, and the average weight of the berries during a period of 9 years. Similar data are given for a large number of varieties of raspberries, blackberries, currants, and gooseberries grown at the station.

Cranberry investigations, A. R. WHITSON, L. P. HASKINS, and O. G. MALDE (*Wisconsin Sta. Rpt. 1905*, pp. 282-299).—An account is given of further progress in the cranberry work at the station previously noted (E. S. R., 16, p. 778). In the experiments of 1905 the holding of the winter's flood on the plants up till May 21, instead of April 21, resulted in later blooming and later harvests. Improving the soil by weeding, sanding, and drainage has resulted in warmer soils and less danger from frosts.

A table is given showing the maximum and minimum temperatures on different plats, from July 22 to September 16. It is shown that low temperature of the marshes is "due to radiation from the surface through the air above, producing lower temperatures than that of the general mass of the atmosphere a short distance above." The difference in temperature in the vines at the ground surface and 3 ft. above averaged 5.22° over a period of 58 days.

In the experiments in draining the marsh at different depths practically the

same yields were obtained in 1904, whether the water was held at the surface, 4 to 8 in. below the surface, or 14 in. below the surface. In 1905 the heavier yields were obtained on the more thoroughly drained plats.

Data are given showing the relation of frost formation to humidity, rainfall, and evaporation, and the seepage in reservoirs. Covering plats from 1½ to 2 in. deep with sand reduced the yield of fruit the first year, but resulted in a very vigorous growth of vines. The cost of sanding, when the sand was hauled 1¼ miles, was at the rate of 40 cts. per yard.

To determine the effect of lime carbonate on cranberries, a plat containing about 8 sq. rd. was treated with 500 lbs. of air-slaked lime. The first season the vines on this plat grew as well as those on adjacent plats, but the next year the vines on this plat remained red throughout the summer, showing no growth whatever, and many died out entirely. It is believed these results indicate that hard water would be fatal to the growth of the cranberry.

A number of experiments were made with fertilizers, from which it appears that the use of a mixture of about 250 lbs. acid phosphate, 75 lbs. nitrate of soda, and 75 lbs. of sulphate of potash per acre each year might be profitable on vines in heavy bearing. The application should be made soon after the winter's flood is withdrawn.

Good results were obtained in the planting of new bogs by scattering the vines before the ditches were dug. The soil from the ditches was then pulverized and mixed into thick mud and poured over the vines in small ridges about 1 ft. apart. While wasteful of vines, this method resulted in more rapid growth than on unsanded bogs. Good results were also obtained by planting cuttings in rows on sanded bogs. Also in planting on narrow ridges about 2½ ft. wide and 1 ft. high.

Observations on the keeping qualities of green and ripe fruit showed that when berries were picked September 8, the following April 36.5 per cent were sound; when picked on September 24, 46.9 per cent, and on October 8, 44.2 per cent were sound.

Notes are given on the cranberry fruit worm and on the value of flooding the vines as a means of control. The investigations on cranberry blight indicate that the amount of blight is largely controlled by the vitality of the vines.

Tannic acid as a fertilizer for grapes, L. E. CAVAZZA (*Italia Agr.*, 43 (1906), No. 16, pp. 390-392, figs. 3).—A general discussion is given of the utilization of organic material by vegetables, with an account of the use of tannic acid and tannate of iron as a fertilizer for grapes. The results secured are not conclusive, but indicate that tannic acid, if not in excess, is not harmful to vegetation, and in the form of tannate of iron resulted in considerably better growth of vines than where nothing was added.

Report of the coffee specialist, J. W. VAN LEENHOFF (*U. S. Dept. Agr., Office Expt. Stas. Bul.* 171, pp. 42-47, pls. 2).—This report covers the work done at the Porto Rico Experiment Station for the year 1905.

A large number of varieties of coffees have been imported from different sections of the world and planted, extensive plantings of Porto Rico coffee made, and experiments in the improvement of an old coffee grove begun. The cost of preparing and planting an acre of land for coffee was found to be about \$60. The yield of coffee obtained on several experimental plats, differently fertilized, is given. Various diseases and insect pests which affected the crop during the year are briefly noted.

Cross pollination of almonds, J. P. DARGITZ (*Pacific Rural Press*, 72 (1906), No. 10, p. 147).—The author gives an account of the bearing of 300 acres of almonds planted with different varieties.

The I X L variety has yielded but one fair crop, though the trees are 17 years old. When planted in alternate rows with Drake Seedling or Texas Prolific, they have borne quite regularly and heavily. Both the Drake and Texas Prolific bear regularly and well. When Nonpareils were planted in alternate rows with I X L the results have been unsatisfactory. The Texas seems to be a much better pollenizer for the Nonpareil than any other variety. At present all I X L trees are being worked over to Texas Prolific, and the author states that if planting out a young orchard he would plant Nonpareils and Texas Prolific in alternate rows, or Drake Seedling and Texas Prolific in the same manner.

Progress in drug-plant cultivation, R. H. TRUE (*U. S. Dept. Agr. Yearbook 1905*, pp. 533-540, pls. 3).—Popular descriptions and cultural directions are given for the growing of Golden Seal, Cascara Sagrada, Seneca snakeroot, purple cornflower, American wormseed, jimson weed, poke, burdock and yellow dock, Asiatic poppy, foxglove, and peppers as drugs. The demand for each of these is rather limited, and it is recommended that prospective growers in the beginning cultivate only small areas.

Hybrids and hybridization among bulbous plants, C. G. VAN TUBERGEN (*Gard. Chron.*, 3 ser., 40 (1906), No. 1025, pp. 132-134).—This is a paper presented before the Hybridization Conference in London, in which the author gives an account of some of the hybrids obtained with *Lilium*, *Bruusvigia josephinae*, *Colchicum*, *Eremurus*, *Freesias*, *Gladiolus*, *Hymenocallis*, *Iris*, and *Nerine*.

Compilation of analyses of fruits, garden crops, and insecticides, H. D. HASKINS (*Massachusetts Sta. Rpt. 1905*, pp. 184-199).—Compiled analyses with reference to fertilizing constituents are given for a large number of orchard and small fruits, grapes, and vegetables, including sugar beets, potatoes, corn, and tobacco, with a table showing the relative proportions of phosphoric acid, potassium, and nitrogen in vegetables, and analyses of 20 insecticides. The composition of 20 prominent garden crops shows on the average, in a thousand parts, nitrogen 4.1, potassium oxid 3.9, and phosphoric acid 1.9 per cent.

FORESTRY.

Administration report of the forest circles in the Bombay presidency, including Sind, for the year 1904-5 (*Admin. Rpt. Forest Dept. Bombay, 1904-5*, pp. 170).—The usual schedule reports are given showing the reserved, protected, and unclassed forests in the northern, central, southern, and Sind forest circles, with an account of the work of the year, etc. The appendices as usual show the detail of expenditures incurred in the different circles and receipts from different sources, the progress made in working plans, statement of forests surveyed, etc.

Reports on forest administration in Burma for the year 1904-5 (*Rpts. Forest Admin. Burma, 1904-5*, pp. 173).—An outline is given of the forestry work done during the year in each of the forest circles of Pegu, Tenasserim, northern, and southern, with a general summary of the same by the Chief Conservator of Forests, F. B. Bryant.

Under the subject of silviculture it is stated that the natural reproduction of teak is generally scarce or even absent in areas which have been long protected from fire, and that where areas are annually burnt over reproduction is generally satisfactory. Selection fellings in moist forests under fire protection have not usually been followed by satisfactory teak reproduction.

Forestry conditions in Canada, U. SCIECK (*Ber. Land u. Forstw. Auslande, 1906, No. 11, pp. 122, map 1*).—A popular account is given of the physical features, agriculture, and forestry conditions of the different provinces of Canada.

How to grow young trees for forest planting, E. A. STERLING (*U. S. Dept. Agr. Yearbook 1905, pp. 183-192, pl. 1, fig. 1*).—Directions are given for growing seedling forest trees from seeds planted in the nursery.

Conifer seedlings should be kept under partial shade for at least two years before transplanting. A shade made by spacing lath about an inch apart is about right. The lath shade framework should be about 18 inches high and erected as soon as the seed is put in the ground. After transplanting at two years of age seedlings will require no further shading. No shade is required for the broad leaf species, but such seeds as the locust, coffee tree, mulberry, and hackberry should be treated with water heated nearly to the boiling point and allowed to soak 4 or 5 days before planting.

Woodlot thinning, E. E. BOGUE (*Forestry and Irrig., 12 (1906), No. 8, pp. 385-388, fig. 1*).—A detailed account is given of the thinning of $\frac{7}{10}$ of an acre of woodland, showing the number and kinds of trees on the land, the number removed, the average diameter, etc.

The nascent forest of the Miscou beach plain, W. F. GANONG (*Bot. Gaz., 42 (1906), No. 2, pp. 81-106, figs. 14*).—An account of the forest flora of the island forming the northeastern angle of the Province of New Brunswick. In many respects, it is stated, the vegetation of this beach plain closely resembles that of the sand beaches and dunes of Lake Michigan.

Sugar pine and western yellow pine in California, A. W. COOPER (*U. S. Dept. Agr., Forest Serv. Bul. 69, pp. 42, pls. 4*).—The author discusses the range and distribution of the yellow and sugar pines, the species with which they are associated, various forest types, botanical characteristics of each, and methods of lumbering observed in California. He gives data showing the average number of trees and percentage of each species per acre at the various elevations in two counties of California, the rate of growth, and diameter and height of the trees, with suggestions for conservative methods of lumbering. Data are also given showing the character of the wood and the commercial importance of these trees in the West.

Yellow pine ranges from central British Columbia, east to the Black Hills, and south to Arizona and New Mexico, while sugar pine is limited to small portions of the Pacific mountains. The sugar pine is one of the most intolerant trees of the Sierra conifers. In its early growth, however, it is shade demanding, and may be stunted or even killed in full light. Tests indicate that not more than 25 per cent of the seed is germinable. The matured trees are very resistant to fires, being rarely killed.

Yellow pine can stand much more drought than sugar pine and is less demanding as regards soils. During early life it grows much more rapidly in both height and diameter than sugar pine, but at the age of 100 years is surpassed by the sugar pine, which attains to a greater height and diameter.

Sugar pine closely approaches eastern white pine in its physical characteristics and is used for practically the same purposes. The yellow pine is considerably heavier than sugar pine and proportionately stronger. In 1904, 289,000,000 ft. of yellow pine was lumbered in California and 128,000,000 ft. of sugar pine. Under present methods of lumbering but few companies cut trees under a diameter of 24 in. on the stump. The average cost of getting the logs to mill is placed at \$5 per thousand, and it is estimated that few companies can place lumber on railroad tracks for less than \$14 per thousand.

The general conclusion is drawn that conservative management of the sugar and yellow pine forests of California is practicable, and that the greatest ob-

stacle to securing a future crop of timber is fire. It is believed, however, that effective fire protection is possible at a reasonable cost.

Waste in logging southern yellow pine, J. G. PETERS (*U. S. Dept. Agr. Yearbook 1905*, pp. 483-494).—The author reports the results of an investigation of the waste in logging southern yellow pine when the timber is owned by one man but sold to and lumbered by another on a stumpage basis. The results of the investigations apply particularly to Mississippi, Louisiana, and Texas, where the cost of producing lumber is placed at \$8 a thousand.

An examination was made of 8 cuttings. About 6 per cent of the trees left standing were found to be part merchantable culls. Of the trees which should have been left standing for future crops, about 25 per cent were broken down or otherwise destroyed by careless logging. The amount of waste in the top logs, where 16 feet is assumed to be the shortest merchantable log length, was 667 feet per acre, and where 12 feet is thus assumed, 962 per acre, the market value of which was \$9.92 per 1,000 feet.

The waste in cutting sound stumps high was found to be 218 board feet per acre, or 1.85 per cent of the total yield. The losses also in the use of sound timber for skid poles, corduroys, bridge timber, etc., was estimated and found to be considerable. Rules are suggested for the prevention of waste in logging yellow pine.

Notes on the Benguet pine, W. M. MAULE (*Forestry and Irrig.*, 12 (1906), No. 8, pp. 355-359, figs. 5).—A description of the Benguet pine (*Pinus insularis*) is given, with an account of its occurrence, growth, and character. It is one of the two principal species of pines native to the Philippines. A table is given showing the diameter growth of trees from 37 to 145 years old. This varies from 15 to 34 inches.

Ornamental and shade trees, P. B. KENNEDY (*Nevada Sta. Bul.* 61, pp. 61, figs. 27).—Popular directions are given for the culture of shade trees in Nevada, with brief descriptions of a large number of trees and shrubs.

Prolonging the life of telephone poles, H. GRINNELL (*U. S. Dept. Agr. Yearbook 1905*, pp. 455-467, pl. 1, figs. 4).—The author estimates that there is in operation at the present time in the United States 800,000 miles of pole lines and that the average length of life of untreated poles is 12 years. For the maintenance of the present lines over 2,650,000 poles are required annually. The length of life of poles may be considerably increased by treating with preservatives.

An account is given of a number of experiments under way by the Forest Service to determine the best methods of treatment, cost, and the increased length of life due to the treatment. The cost of a green pole at the setting hole is estimated at \$5. If preservatives are applied to the outside of the pole between 2 feet and 8 feet from the butt the cost is placed at \$5.40 and the increased length of service of the pole 4 years. If the butts are soaked in tanks for a distance of 8 feet the cost at the setting hole is placed at \$5.65 and the increased length of service over untreated poles is about 8 years. In other words, the annual cost for a green pole is 53.28 cents, of a pole treated by the first method noted above 46.34 cents, and by the second method 41.57 cents.

An attempt was made to force preservatives into the butts of poles, but owing to the presence of seasoning checks the penetration was not uniform and this method was discarded.

Memorandum on mechanical tests of some Indian timbers, W. H. EVERETT (*Calcutta: Govt.*, 1906, pp. 7).—Tabulated data are given showing the results of mechanical tests of about 100 pieces of wood, representing many different species of trees. The data cover shearing strength, crushing strength, bending strength, and stiffness.

DISEASES OF PLANTS.

Report on plant diseases prevalent in Nebraska during the season of 1905. F. D. HEALD (*Nebraska Sta. Rpt. 1905, pp. 19-81*).—Notes are given on the occurrence of a large number of plant diseases observed in Nebraska during the period covered by this report, the data being arranged under different groups according to the host plants. In addition suggestions are given for the prevention of these diseases, so far as means are known.

Infection experiments with Erysiphe graminis, G. M. REED (*Reprinted from Trans. Wis. Acad. Sci., Arts, and Letters, 15 (1905), pt. 1, pp. 135-162*).—The author reviews the investigations of a number of experimenters on the specialization of mildews, the investigations seeming to indicate that "although there are definite physiological species, normally restricted to one or a few host plants, yet injured host plants of one physiological species may be infected by spores of another physiological species and, in this way, the mildew may be bridged over from one host plant to another."

The author reports a considerable number of infection experiments, using the conidia of *E. graminis* from blue grass and rye. For the most part he has sought to infest grasses that are in common cultivation and which are consequently often exposed to infection from both rye and blue grass. To test the results reported by Marchal (*E. S. R., 14, p. 666*) spores from rye were sown on wheat, oats, barley, wild barley, soft brome grass, and a number of species of *Poa*. With one exception, none of the seedlings or leaves inoculated became infected, although the experiments were continued from 8 to 15 days. A further experiment showed that the spores from rye would not infect other cereals. The experiments with mildew from blue grass showed that this mildew would not readily infect the other species of *Poa* experimented with.

In conclusion the author states that his experiments indicate that spores of the mildew from one grass will not infect a grass belonging to a different genus. It is quite possible that for *E. graminis* there is one, if not more, distinct physiological species for each genus of grasses that contains species which are hosts for this mildew. In many genera of grasses the specialization has undoubtedly gone still further, so that there may be a number of physiological forms upon the various species of the same genus. This is indicated by the author's work with various *Poas* and leads him to the conclusion that there is more than one at least partially differentiated physiological form for this genus alone.

A brief bibliography concludes the publication.

A preliminary report on the blast of rice, H. METCALF (*South Carolina Sta. Bul. 121, pp. 43*).—This bulletin is the result of studies and investigations on rice diseases carried on in cooperation between the South Carolina Experiment Station and the Bureau of Plant Industry of this Department. The present bulletin is preliminary, and further investigations are to be carried on with fertilizers and other methods of soil treatment, as well as experiments to determine the exact nature of rice blast.

Rice blast is known to be present in practically all of the regions devoted to rice culture in South Carolina and it has also been reported from Louisiana and Texas. In addition to lowland rice it is known to affect upland rice wherever grown in South Carolina, and while in general the disease resembles that called brusone in Italy, it does not appear to be identical with it.

The characteristic features of rice blast are distinct lesions at one or more joints. Beginning as small spots on the sheath nodes the tissues underneath gradually die until the joint is partially or entirely involved. In consequence the parts of the plant above the affected joint die by degrees. This cutting off may take place at any joint above the water and at any stage from the shooting

of the head until the grain is mature. According to weather conditions and the length of time that the dead top of the stalk is subject to the action of weather, it may appear bleached, blackened, or discolored in various ways. Very frequently the stalk breaks off at the point of attack, and in 70 per cent of all cases observed the point of infection was at the lowest joint on the rachis, or what is popularly known as the neck. If the lesion is below the neck, the first sign of the disease is one or more minute spots, which appear on the sheath node directly above the joint. At first the tissues appear water-soaked and sunken and later the spots become discolored, brownish, or black. This discoloration spreads up the sheath, but usually for not more than an inch, and downward for a distance of one-fourth to one-half inch. The spot becomes more shrunken and extends laterally, girdling the stem. The skin becomes broken, resulting in an open wound, which may appear blackened from the growth of various organisms on the dead tissues. A microscopical examination of the neck shortly after the appearance of the spot reveals the presence of the spores of a fungus, but as yet it has not been positively identified. Thus far experiments have not determined the exact cause of the disease.

The rice blast does its damage by arresting the development of grain, which may be done at any time. The financial losses due to this cause are very great, and in some localities the disease has resulted in the abandonment of rice cultivation.

Investigations conducted to determine whether the disease might be distributed by other plants than rice seem to indicate that while it may affect a few species of plants, such as *Panicum crus-galli*, yet it is improbable that the disease can originate or spread from this source.

A number of typical cases of blast, as observed in plantations, are described, after which the author discusses the conditions of spread and methods of control. So far, there does not appear to be any connection between the disease and weather conditions, nor is there any evidence that the blast is transmitted by seed. There does appear, however, to be a distinct relationship between the soil conditions and the disease. It has been shown that the blast may be readily produced by inoculating healthy plants directly from diseased ones, but so far it has not been produced by pure cultures of any one organism. The disease occurs in its most virulent form on rested land, land that has been recently reclaimed, or land that is fertilized with nitrogenous fertilizers.

In considering methods of control, the author discusses water treatment, the use of fertilizers, spraying, securing immune plants, etc. The best results have been obtained where marl or lime were used as fertilizers. It is believed that the disease has practically run its course in South Carolina and will not spread further unless nitrogenous fertilizers are used or resting is practiced on these lands that are annually producing poorer and poorer crops. Such lands should be treated with great care and should not be rested under any circumstances, nor should nitrogenous fertilizers be applied to them.

So far as known, there are no varieties of rice that are entirely immune to this disease, and variety tests and selections for immunity have thus far failed.

Brief notes are given on other diseases of rice, among them smut, rust, damping off, spotted blight, etc., most of these diseases being fairly well known and capable of control.

A brief list of works relating to rice diseases completes the bulletin.

Diseases of sweet potatoes in Alabama, E. M. WILCOX (*Alabama College Sta. Bul. 135, pp. 16, figs. 4*).—A preliminary report is given on some of the diseases to which the sweet potato is subject in Alabama, the principal ones described being black rot, dry rot, scurf, soft rot, soil rot, stem rot, and white rot. Where preventive treatments are known the author has described them.

A bibliography of the more important literature relating to the diseases of the sweet potato completes the bulletin.

A new bacterial disease of the pods of some leguminous plants, E. VON OVEN (*Centbl. Bakt. [etc.]*, 2. Abt., 16 (1906), No. 1-3, pp. 67-74, pl. 1).—A description is given of a bacterial disease of peas and other leguminous plants that was investigated by the author in 1905. The disease was first noticed in the vicinity of Berlin and proved very destructive. Its cause is said to be *Bacillus leguminiperdus* n. sp., which attacks the fruiting pods of peas, beans, wax beans, lupines, etc., and possibly will be able to destroy the fruits of other plants, particularly those of tomatoes. The diseased pods appear to be smaller and ripen earlier, the ripened fruits being darker and quite unlike the normal ones. The organism was isolated and cultivated in pure cultures, and inoculation experiments showed the possibility of transferring it to all available legumes, tomatoes, etc. The organism is said to be very unlike that of *Bacillus phasecoli*, previously recognized as causing disease of beans, etc. (E. S. R., 9, p. 1058.)

Apple scab in eastern Washington, W. H. LAWRENCE (*Washington Sta. Bul.* 75, pp. 14).—In a previous publication (E. S. R., 16, p. 573) the author gave the results of a study of the life history of the fungus causing apple scab in western Washington, and also some experimental work in combating it. In the present bulletin an account is given of additional work recently carried on in the eastern part of the State, where the climatic conditions are quite different from those reported in the previous publication.

The general development of the fungus in the eastern part of the State was noted, but no additional facts were found regarding its life history. The rapid increase in the amount of disease is shown in a table, giving the percentage of the disease on 12 varieties during the past season, which shows an average increase of 52 per cent in scabby fruit.

Experiments were carried on for the prevention of the disease in which trees were sprayed with ordinary Bordeaux mixture and also dust Bordeaux. On 85 trees representing 15 varieties sprayed with dust Bordeaux, the average percentage of clean fruit was 13 per cent, while on 50 trees representing the same number of varieties that were not sprayed the average percentage of clean fruit was 6 per cent. On the other hand, 60 trees representing 8 varieties that were sprayed with liquid Bordeaux gave an average of 89 per cent clean fruit, showing the evident superiority of the liquid Bordeaux for the prevention of this disease.

Notes are given on the preparation and application of the fungicides.

The black rot of apples due to *Sclerotinia fructigena*, F. D. HEALD (*Nebraska Sta. Rpt. 1905*, pp. 82-91, pls. 2).—Attention is called to the fact that the rotting of fruits by *Sclerotinia fructigena* has generally been characterized as the brown rot, and that some symptoms attending this rot have hitherto escaped American and English investigators.

The form here described is that known as black rot, which has been noted by several German investigators, and is attributed to attacks of *Monilia*. As the black rot due to *Monilia* and that caused by *Sphaeropsis malorum* have been confused, attention is called to some of the external differences. In apples affected by the *Monilia* the skin is shiny, coal black, smooth, and perfectly free from external evidence of fungus mycelium or fruiting bodies, while in the case of fruits attacked by *Sphaeropsis* the surface of the apple is sometimes brown and soon becomes dotted with black pustules containing the pycnidia of the fungus. The areas between the pustules are darkened, giving the whole surface a dark brown or black color. In *Monilia*-affected apples the fruit does not shrivel

greatly, while, on the contrary, those affected with Sphaeropsis become greatly reduced in size and exhibit an irregular wrinkled surface. Experiments with cultures and inoculations show the difference in the two diseases.

The author believes that a lack of moisture is one of the important factors in determining the development of the Monilia. The precautions taken to prevent the occurrence of scab and other fungus diseases by spraying with Bordeaux mixture, removing mummy fruits, etc., are recommended for the prevention of this disease.

A brief bibliography completes the account.

Pear blight (*Oklahoma Sta. Rpt. 1906, p. 43*).—A summary is given of a press bulletin previously issued by the station calling attention to pear blight and giving suggestions for its control. The varying susceptibility of different varieties to blight is pointed out and the desirability of additional data in respect to liability to disease is indicated.

The ripe rot or mummy disease of guavas, J. L. SHELDON (*West Virginia Sta. Bul. 104, pp. 299-315, pls. 4, fig. 1*).—The author reports having observed in the greenhouses of this Department some diseased guavas, from which material was collected for study on account of the similarity of the disease to the bitter rot of apples. Supplemental material was obtained from Porto Rico and Florida, and a study made of the fungus and its effect upon the fruit.

The disease, which has been previously described as due to *Glucosporium psidii* (E. S. R., 16, p. 477), seems to be rather widely distributed, and the fungus is known to occur in Porto Rico, Florida, California, Mexico, and Australia.

When infested by the fungus brown spots appear on the ripening fruits, and these spots gradually increase until the entire fruit becomes affected, the decayed fruits finally falling off or remaining on the trees as mummies.

A study of the fungus to determine its relationship with allied species led the author to believe that it should be associated with the genus *Glomerella*.

The presence of copper in olive oil obtained from fruit sprayed with Bordeaux mixture, N. PASSERINI (*Atti R. Accad. Econ. Agr. Georg. Firenze, 5. ser., 3 (1906), No. 1, pp. 139-144*).—In the author's investigations olive oil was found to contain traces of copper whether the trees had been sprayed or not. The amount found in oil from olives grown on sprayed trees was not appreciably greater than from olives grown on unsprayed trees. The quantity present, which was less than 1 mg. per kilogram of oil, was so small as not to be injurious when eaten. The quantities found ranged from traces to 0.49 mg. per kilogram in oil from olives on untreated trees and from a mere trace to 0.47 mg. on treated ones.

Combined treatment for powdery and downy mildew, L. HUGOUNENQ (*Rev. Vit., 25 (1906), No. 644-646, pp. 429-433*).—In commenting upon the efficiency of the treatment suggested for these diseases (E. S. R., 17 p. 876), in which the addition of an alkaline polysulphid to a neutral copper acetate solution was recommended, the author states that this fungicide proved very adhesive and quite efficient in combating both diseases.

The addition of the polysulphid to the copper solution is said to result in the formation of a chocolate-colored precipitate mixed with a small quantity of sulphur. When sprayed upon foliage this copper polysulphid becomes copper sulphid through exposure to the air and later is further changed into copper sulphate and sulphur.

Experiments in combating downy mildew of grapes, N. PASSERINI (*Atti R. Accad. Econ. Agr. Georg. Firenze, 5. ser., 3 (1906), No. 1, pp. 145-148*).—Experiments are reported which were carried on in 1905 relative to the efficiency of copper sulphate neutralized with lime; copper sulphate and iron sul-

phate neutralized with lime; copper sulphate, alum, and lime; and iron sulphate neutralized with lime, these fungicides being tested for the control of downy mildew of grapes.

Groups of vines in the vineyard were sprayed under similar conditions, 4 applications being given them, and the effect of the treatment was determined by a committee of inspection. The amounts of copper per unit of leaf surface after the different sprayings up to the beginning of October are reported.

In every case more copper was present where the vines had been sprayed with a 0.5 per cent solution of copper sulphate neutralized with lime than on any of the other lots. Iron sulphate was found to be without appreciable effect in checking the downy mildew. The addition of iron sulphate to the copper solution diminished the efficiency of the Bordeaux mixture, and the solution to which alum was added was not as valuable as that in which copper sulphate and lime alone were used.

American gooseberry mildew (*Dept. Agr. and Tech. Instr. Ireland Jour.*, 6 (1906), No. 3, pp. 445-447, pl. 1, figs. 2).—An account is given of the gooseberry mildew (*Spharotheca mors-uvæ*), which is reported as occurring on red currants in Kilkenny County, Ireland, and a warning is given regarding its possible spread. For its prevention the author recommends spraying with a solution of 2 oz. of potassium sulphid in 3 gal. of water.

A disease of cottonwood due to *Elfringia megaloma*, F. D. HEALD (*Nebraska Sta. Rpt.* 1905, pp. 92-100, pls. 4).—The author reports having observed specimens of living cottonwood in which the entire heart and sapwood were permeated by the mycelium of the fungus *Elfringia megaloma*, which produced a gradual dissolution or decomposition of the wood cells and rendered the wood soft and punky in some instances and very brittle in others.

A brief historical statement is given regarding the distribution of this fungus, the symptoms produced, the anatomy of the host plant, etc., and suggestions are given for its control, which consist in the removal of the diseased trees, destruction of the sporophores, etc.

Peridermium cerebrum and Cronartium quercuum, C. L. SHEAR (*Jour. Mycol.*, 12 (1906), No. 83, pp. 89-92).—The common occurrence of *Peridermium cerebrum* on trunks of ordinary pine about Washington and also the abundance of *Cronartium quercuum* on oaks in the same vicinity led the author to an investigation to determine the possible connection between the two forms.

A number of inoculation experiments were undertaken, and the large number of sori occurring on most of the artificially inoculated leaves as compared with the very small number found on the surrounding ones, taken in connection with their much earlier appearance, seems to indicate a genetic relation between the two forms. While the matter can not be regarded as settled, the evidence at hand seems to indicate the connection between the species of *Peridermium* and the uredo and teleutospore stages which are found on various species of oaks.

A list of species of pine and oak upon which the two forms are found is appended.

The adherence of copper fungicides, G. GASTINE (*Bul. Mens. Off. Renseig. Agr. [Paris]*, 5 (1906), No. 5, pp. 595-603).—After giving a summary of the investigations of Girard (E. S. R., 3, p. 734) and Guillon and Gouirand (E. S. R., 10, p. 651), the author describes his investigations relative to the adhesiveness of various copper fungicides.

The coefficients of adhesiveness were determined in a manner somewhat different from that usually employed. The fungicide was thoroughly distributed over grape leaves and glass plates, and after drying, the leaves and plates were washed and the amount of copper removed determined. The proportion between

the amount remaining and the original amount is given as the coefficient of adhesion.

The fungicides tested were Bordeaux mixture, soda Bordeaux, copper acetate solutions, ammoniacal copper carbonate solution, and several special trade preparations. All the fungicides were so prepared as to contain approximately the same amounts of copper.

In the summary of the author's conclusions it is shown that the alkaline Bordeaux mixture made by what is termed the American method and the same mixture to which molasses or linseed oil was added were the most adhesive, from 90 to 95 per cent of the copper remaining on the leaves. Neutral Bordeaux mixture had a coefficient of 75 to 80 per cent, and acid Bordeaux mixture 50 to 55 per cent. The adhesiveness is said to be diminished by mixing the copper sulphate and lime in too concentrated forms. Delay in application after preparation reduces adhesiveness, although the molasses Bordeaux mixture retains its coefficient of adhesiveness after standing for 48 hours. Neutral soda Bordeaux mixture had a coefficient of 85 per cent when made by the American method. Where this mixture was alkaline 72 to 75 per cent remained on the leaves. When freshly prepared from dry powdered chemicals it had a coefficient of 70 to 75 per cent, but if the powders were allowed to stand for several hours the adhesiveness fell to 50 per cent or less. This was also found true for a number of proprietary mixtures which are sold in powdered form. All the mixtures containing carbonate of soda lost their adhesiveness rapidly, and after standing during 2 days of warm weather prior to application to the foliage all traces of copper were removed by the washing process. Mixtures to which soap or sugar was added differed but little from ordinary soda Bordeaux mixture in their adherence.

In general the copper acetate solutions were less adherent than those described above. Neutral copper acetate had a coefficient of 50 to 52 per cent, but by the addition of sulphate of soda it was increased to 58 to 65 per cent. By the addition of kaolin to neutral copper acetate the coefficient of adhesiveness was increased to 65 to 72 per cent, and where ammonia was added it was increased to 80 to 83 per cent. The copper acetate and ammoniacal solutions did not seem to depreciate very much on standing. Eau celeste had a coefficient of 56 to 58 per cent, ammoniacal copper carbonate solution 73 to 76 per cent, and copper formate 82 to 83 per cent.

In practice the forms of Bordeaux mixture give the best results, but they offer many difficulties of preparation and application that the copper acetate solutions do not. On this account the author believes that solutions will probably be found adapted to general use, although their adherence to the foliage is not as perfect as those fungicides containing lime.

The use of dilute solutions of sulphuric acid as a fungicide. II. KRAEMER (*Science, n. ser., 23 (1906), No. 599, p. 941*).—In a paper presented at the celebration of the two-hundredth anniversary of the birth of Benjamin Franklin, the author gives the results of the use of dilute solutions of sulphuric acid as a fungicide for preventing the mildew on roses.

The fungicide was tested on plants growing outdoors as well as in the greenhouse, and the application of a solution containing approximately 1 part of sulphuric acid to 1,000 parts of water was employed. The roses were uninjured by the acid solution, and they began immediately to develop new leaves and young shoots entirely free from mildew after from 3 to 6 applications on alternate days. Should subsequent experiments confirm these observations, the use of sulphuric acid will have certain advantages over the use of sulphur, as it does not discolor the foliage and its employment is more easily controlled.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Federal game protection. A five years' retrospect, T. S. PALMER (*U. S. Dept. Agr. Yearbook 1905*, pp. 541-562, pl. 1, figs. 13).—A summary is presented of the main features in the work of game protection in the past five years. The chief points considered are the Lacey Act, importation of foreign birds and mammals, interstate commerce in game, cooperation of this department with State officials and Audubon societies, and the game preserves.

Directory of officials and organizations concerned with the protection of birds and game, 1906, T. S. PALMER (*U. S. Dept. Agr., Bur. Biol. Survey Circ. 53*, pp. 16).—The purpose of the present directory is to furnish the names of persons in the different States and Territories from whom information may be had respecting the local game laws and the requirements which must be met by individuals who wish to hunt in different localities.

The zoological record, D. SHARP (*Zool. Rec.*, 41 (1904), pp. LXX + 1202).—In this volume detailed bibliographical lists are given of literature relating to the various groups of the animal kingdom and published for the most part during the year 1904.

Meadow mice in relation to agriculture and horticulture, D. E. LANTZ (*U. S. Dept. Agr. Yearbook 1905*, pp. 363-376, pls. 4, figs. 1).—Of the 165 species of *Microtus* known to science about 78 are found in North America. Some species of meadow mice show a very large distribution and often occur in such numbers as to be a serious menace to fruit raising and gardening.

The feeding habits of meadow mice are described and notes are given on their natural enemies, which include a number of birds and mammals. The unusual prevalence of meadow mice in certain localities is attributed to the destruction of their natural enemies.

Considerable success in the control of meadow mice has been had with the use of grain or some other form of bait poisoned with strychnine, the drainage of swamps, a periodic plowing of grass lands which serve as breeding grounds for meadow mice, and the destruction of weeds and dead grass in the fall by burning or other methods.

Requirements to be complied with by nurserymen or others who make interstate shipments of nursery stock, A. F. BURCESS (*U. S. Dept. Agr., Bur. Ent. Circ. 75*, pp. 6).—This circular contains in a condensed form the essential requirements of the laws of various States regarding the shipment and introduction of nursery stock. A more complete account of these laws will soon be published by the Bureau of Entomology.

Report of the entomologist, D. L. VAN DINE (*U. S. Dept. Agr., Office Expt. Stas. Bul. 170*, pp. 38-59, pl. 1).—A brief account is presented of the organization of entomological work in Hawaii and of the working staff and equipment.

Bee keeping is fostered to a considerable extent, and the author presents a list of native and introduced bee plants. Likewise with silk production much energy is being expended in encouraging this industry, and it appears to be well suited to the conditions of the Hawaiian Islands. Quite favorable results were obtained from a test of cold storage in the shipment and preservation of silkworm eggs. A committee of citizens has been appointed to make a study of the situation with regard to mosquitoes and considerable work has been done in the study of fish which eat mosquitoes.

A partial list is presented of the insects injurious to various cultivated crops in Hawaii and a bibliography is given of publications relating to Hawaiian entomology.

Report of the entomologists, C. H. and H. T. FERNALD (*Massachusetts Sta. Rpt. 1905*, pp. 149-152).—During 1905 a number of injurious insects were ob-

served in unusual abundance. Particular attention was given to the study of the San José scale, cutworms, army worms, and various other pests, as well as to fumigation of greenhouses. The authors state that the gipsy moth is now spreading rapidly over the State.

Fifth report of the State entomologist and plant pathologist of Virginia, J. L. PHILLIPS (*Rpt. Va. State Ent. and Plant Path., 5 (1904-5), pp. 88, figs. 14*).—In this report an account is given of the work in controlling the San José scale in Virginia in the years 1903-1905. The organization and scope of the work is described with notes on nursery and orchard inspection. In growing nursery stock free from San José scale it is recommended that a site be selected as little infested as possible with no orchards near the intended nursery. All stock should then be fumigated and after the first winter should be treated twice annually with lime and sulphur wash.

An account is presented of the present status of nursery and orchard inspection in Virginia, with a description of fumigation methods and their effectiveness as applied under different conditions for the destruction of San José scale, scurfy scale, and other pests. The action of hydrocyanic acid on nursery stock was also studied, with the result that this appeared not to be a serious matter under ordinary conditions. The only common causes of unsatisfactory results in fumigating nursery stock are the use of adulterated potassium cyanid and the practice of fumigation during midwinter when the scale insects are least susceptible to fumigation.

Detailed directions are given on the preparation and effectiveness of lime-sulphur wash made according to different formulas and various other insecticide preparations.

Report of the entomological division, W. R. DEWAR (*Orange River Colony Dept. Agr., Ann. Rpt., 1 (1904-5), pp. 183-238, figs. 8*).—The organization and work of the division of entomology are briefly outlined with notes on the routine work.

Particular attention is being given at present to the control of locusts by means of arsenical solutions and by other methods, as well as to the distribution of ladybirds, control of noxious weeds, and study of various miscellaneous insects, including ticks, *Bagrada hilaris*, cabbage aphid, diamond-back moth, potato moth, bean weevils, boll weevil, grain aphid, red scale, and other scale insects.

A brief report is made by C. N. Johnston on the birds of Orange River Colony in their relation to agriculture.

Farm practice in the control of field-crop insects, F. M. WEBSTER (*U. S. Dept. Agr., Yearbook 1905, pp. 465-476, pls. 2, figs. 2*).—In order to control the insects which attack field crops it is necessary that the farmer should have a practical knowledge of the habits of these pests. The best results are obtained by the use of a suitable system of crop rotation combined with thorough plowing at seasons when the insects would be most injured by such operations, good tillage, occasional summer fallowing, and the destruction of weeds and all unnecessary vegetation in which insects may breed.

Proliferation as a factor in the natural control of the Mexican cotton boll weevil, W. E. HUXBS (*U. S. Dept. Agr., Bur. Ent. Bul. 59, pp. 45, pls. 6*).—In the study of the cotton boll weevil by the Bureau of Entomology, attention is given to all details which may in any way bear upon the control of this pest. In 1902 it was noted that the cotton plant has a tendency to protect itself by proliferation of cells at the point of injury by the cotton boll weevil in the squares or bolls. A thorough study of this phenomenon has been carried on to date and statistics collected bearing on the problem of the effectiveness of this tendency of the plant in controlling the pest.

It appears from these observations that in many varieties of American upland cotton proliferation takes place in 51 per cent of the cases of weevil attack upon squares and in 55 per cent of those upon bolls. The increased rate of mortality among weevils as a result of this proliferation was found to be 13.5 per cent in squares and 6.3 per cent in bolls. Climatic conditions appear to have little effect upon proliferation, and all varieties of American upland cotton appear to proliferate to about the same extent. The use of fertilizers apparently does not increase proliferation and the proliferating tissue is not poisonous to the weevils. Death results from mechanical causes.

Destroying weevils in cowpeas (*Oklahoma Sta. Rpt. 1906, pp. 33-35*).—Brief data are given relative to the amount of damage caused by weevils in cowpeas. Experiments with gasoline and carbon bisulphid showed that the gasoline did not evaporate as readily as carbon bisulphid and is less effective than the latter. One pound of carbon bisulphid was found to be sufficient to treat 40 bu. of cowpeas.

A locust campaign, E. R. SAWER (*Rhodesian Agr. Jour., 3 (1906), No. 3, pp. 225-230*).—Attention is called to the great devastation which may be worked by the locust if these pests are not controlled. The organization of the field work in the locust campaign in South Africa is described. Particular attention is given in this campaign to *Pachytylus sulcicollis* and *Acridium purpuriferum*. The methods of destruction are quite varied, but the most effective and most economic appears to be in the use of an arsenical spray.

Locust birds and locust poisons, C. P. LOUNSBURY (*Agr. Jour. Cape Good Hope, 28 (1906), No. 3, pp. 364-366*).—Several complaints were made that the extensive use of arsenic and other poisons in the destruction of locusts had led incidentally to the poisoning of locust birds from eating the dead locusts. The opinions of a number of entomologists who had experience with this matter in South Africa are quoted to the effect that no such poisoning takes place. It appears that birds or domestic fowls may eat poisoned locusts in considerable quantities without thereby being badly affected.

Codling moth work in 1904, E. D. BALL and E. G. PETERSON (*Utah Sta. Bul. 95, pp. 65-107, figs. 12*).—The authors in their work on the codling moth have proceeded on the basis that the first work to be done is a careful determination of the life history of this pest under local conditions. Various points connected with the habits and life history of the codling moth in Utah were carefully worked out anew so that the practical spraying experiments devised by the authors rested on a scientific basis.

The work reported in the present bulletin had for its chief objects the determination of the relative value of early and late sprays and the separation of the injury caused by the first brood from that of the second. The spraying experiments were carried out in 3 orchards containing a number of varieties. Paris green was applied at the rate of 1 lb. to 120 gal. of water. The early applications were made just after the blossoms fell (May 28 to June 1) and a second time (June 10 to 14). Three late applications were made on August 4, August 18, and September 2. All of the trees were banded and the bands examined every 3 days in order to count the larvæ. All windfalls were carefully examined, and between August 1 and 3 all of the apples on the trees were examined to determine whether the larvæ entered through the calyx or side of the apple.

The observations on the periods covered by the 2 broods of codling moth in Utah indicate clearly that August 1 is about the separating point between the 2 broods. The results of spraying were carefully determined with reference to the production of the first and second broods of codling moth. It appears that two early applications of Paris green killed 89 per cent of the first brood of

codling moth the first year, and 96 per cent where the method was continued for 2 years. It is also learned that two-thirds of the worms entered the apple through the calyx. The two early applications destroyed all but 4 per cent of the worms which attempted to enter through the calyx, while 22 per cent of those which attempted to enter the side of the apple escaped the Paris green.

From observations made in Colorado and elsewhere the authors believe that the second brood is about 5 times as numerous as the first. The average number of wormy apples per tree without spraying was 247 as a result of the attack of the first brood. If the second brood is 5 times as numerous this would make an average of 1,482 wormy apples per tree during the season if unsprayed, while the average number on sprayed trees would be 162 the first year and 66 the following year if the treatment is repeated. The authors also determined that 90 per cent of the worms which entered the calyx during August and September were killed by Paris green which had been applied in June. This indicates the lasting effect of the early applications. The total cost of two arsenical applications, banding and examining the bands during the season, was 14 to 21 cts. per tree or $1\frac{1}{2}$ to 2 cts. per bushel of apples.

As a result of their work on the codling moth the authors conclude that the only proper time for the early spray is just after the blossoms fall and before the calyx closes. It appears that the two early applications of Paris green will kill nearly nine-tenths of the codling moth up to August 1 and that enough poison remains to kill two-thirds of the larvæ of the second brood. The three late applications destroyed three-fourths of the second brood of codling moth, but the early sprays appear to be of much more value than late ones, since late sprayings alone will not save the crop in badly infested orchards.

The codling moth in the Yakima Valley, A. L. MELANDER and E. L. JENNE (*Washington Sta. Bul.* 77, pp. 96, pls. 13, figs. 7).—The codling moth has been known in the State of Washington for 25 years and in the warmer river valleys causes an almost total destruction of the apple crop if no protective measures are taken.

An elaborate test of insecticides was made in a number of orchards, using a gasoline power sprayer in some cases. The habits and life history of the codling moth are described in detail, with especial reference to the bearing of available data upon the number of broods of this pest. In the Yakima Valley there appeared to be 2, and possibly 3, broods of the codling moth, the first and second broods being separated by a period of 3 or 4 weeks.

The authors found that the windfalls rarely contain larvæ of the codling moth. About 70 per cent of the first brood of larvæ attempt to enter the apples at the calyx end within 2 to 5 weeks after the blossoms have fallen. The second brood begins to enter the apples toward the end of July. According to the authors about 60 per cent of the larvæ drop to the ground after leaving the apples, the remaining 40 per cent crawling down the trunk of the tree. It is recommended, therefore, that bands on apple trees should be inspected at intervals not greater than 2 weeks. Rarely pears, peaches, and prunes are infested with the codling moth. Notes are also given on natural enemies of this pest.

In spraying for the codling moth arsenate of lead is recommended as the best remedy. Fruit growers are advised to buy arsenate of lead from reliable dealers rather than attempt to make it themselves. Paris green is also effective when used at the rate of 1 lb. to 125 gal. of water, but London purple and arsenoids are not recommended. If a given neighborhood is not badly infested it will be unnecessary to spray for the second brood; otherwise, light sprayings are required. In such cases two sprayings for the first brood and two or three for the second are recommended. It is believed that spraying every 2 weeks throughout the season is an unnecessarily expensive system. It was found that

trees may be sprayed 4 times with the power sprayer at the cost of 8 cts. per tree, and with the result of saving 90 per cent of the fruits, while 85 per cent of the crop was free from codling moths after two applications.

The gypsy and brown-tail moths and their European parasites, L. O. HOWARD (*U. S. Dept. Agr. Yearbook 1905, pp. 123-138, pls. 2, figs. 8*).—The history of these two pests in the United States is briefly outlined with notes on the appearance and habits of both insects, the artificial remedies commonly used against them, and American parasites which have been thus far found attacking them. The author has succeeded in interesting a number of European entomologists in the work of collecting and shipping parasitized specimens of these insects to Boston, where it is hoped parasites will be reared to assist in controlling the pests.

A test of different sprays for the San José scale, W. E. RUMSEY and F. E. BROOKS (*West Virginia Sta. Bul. 107, pp. 347-354*).—A report is made on the results obtained from the use of 4 brands of proprietary insecticides in controlling the San José scale.

The conclusion is reached that preparations of concentrated soluble oil are the most convenient materials to use in destroying scale insects. They are not only effective, but are easily handled and do not injure the spray pumps, harness, horses, nor the face and hands of the workman.

Directions for checking the cottony scale and the report of State nursery inspection, C. BUES (*Wisconsin Sta. Rpt. 1905, pp. 315-329, figs. 5*).—The cottony maple scale is most easily dislodged from the trees in Wisconsin during the month of June. It is found possible to wash them off the trees by means of a forcible spray of water, and for this purpose the fire department allowed the use of some of its apparatus. Good results are also obtained by spraying in summer with kerosene emulsion and with a strong emulsion in early fall. The work of spraying may be made simpler by suitable pruning of the trees.

A brief statement is given on the condition of nurseries in Wisconsin, and on the present status of San José scale, imported willow weevil, apple leaf hopper, strawberry root louse, apple canker, and other insects and fungus diseases.

The peach-tree borer, H. N. STARNES (*Georgia Sta. Bul. 73, pp. 145-190, figs. 12*).—The borer is not the most important enemy of peaches in Georgia, but in the author's opinion stands about fourth among the pests of this tree. The insect is described in its various stages, and notes are given on its life history as shown by numerous observations made in Georgia and elsewhere.

The methods recommended for the control of the peach borer include wrapping the base of the trees with brown paper or newspaper, mounding the trees with earth, removing the larvæ with steel instruments, and the use of caustic substances for destroying the larvæ. In a series of laboratory experiments it was found that many of the borers were prevented from emerging when buried in the soil to the depth of 3 inches or more. This suggests the possible value of deep plowing just before the borers are ready to emerge from the soil.

The principal insect enemies of the peach, A. L. QUAINANCE (*U. S. Dept. Agr. Yearbook 1905, pp. 325-348, pls. 7, figs. 7*).—About 190 insect enemies of the peach are known to be of more or less importance. Biological and economic notes are given on many of the most serious insects included in this number, the chief among which are plum curculio, peach borer, San José scale, West Indian peach scale, black peach aphid, peach twig-borer, fruit tree bark-beetle, and nematode root-gall.

Some insects injurious to forests. **The western pine-destroying bark-beetle,** J. L. WEBB (*U. S. Dept. Agr., Bur. Ent. Bul. 58, pt. 2, pp. 11-30, pls. 2, figs. 6*).—According to the observations of several members of the Bureau of Entomology, the western pine-destroying bark beetle (*Dendroctonus brevicornis*)

is the most important enemy of the western pine in certain parts of Idaho where the destruction of this tree was investigated.

The presence of the pest is indicated by dead and dying trees and by pitch tubes and small quantities of resin in the crevices of the bark. The insect is found throughout Idaho and from California to Washington and attacks the western yellow pine and sugar pine. It is estimated that from 2 to 5 per cent of pine timber has been destroyed annually by this pest during the past 3 years.

A brief account is given of the observations made by a number of investigators in Idaho, Washington, and elsewhere. The life history and habits of the insect are traced in some detail and brief notes are given on the natural enemies. The pest appears to attack and destroy the best specimens of trees and is capable of devastating pine trees over large areas. The insect passes the winter in the outer bark of trees which were killed during the previous summer. On this account it is recommended that infested trees be located in the fall and cut between October and May, after which the bark should be removed and destroyed.

Insect enemies of forest reproduction, A. D. HOPKINS (*U. S. Dept. Agr. Yearbook 1905*, pp. 249-256, figs. 9).—Insect injuries to forest trees may occur during the period of flowering, fruiting, germinating, or growth of the seedling, sapling, and mature trees. Brief accounts are presented of some of the more noted forest insects and of their attacks upon sprout forests. While ordinary insecticide methods are of some value in the control of forest insects, the chief reliance must be placed on systems of forestry.

Two insect pests of the elm, A. L. MELANDER (*Washington Sta. Bul. 74*, pp. 7, fig. 1).—Elm trees in Washington are sometimes greatly injured by the elm bark-louse. This pest may be controlled by thorough spraying with the lime-sulphur wash during February or March.

The elm leaf-louse is also quite a serious pest, but may be largely controlled by a winter spray of lime and sulphur, or, if this is not given, the use of kerosene emulsion will yield the desired results. Formulas are given for preparing these insecticides.

The mosquito, T. B. SYMONS, T. H. COFFIN, and A. B. GAHAN (*Maryland Sta. Bul. 109*, pp. 71-124, figs. 37).—The agency of mosquitoes in transmitting diseases to man is briefly discussed and descriptions are presented of mosquitoes commonly observed in Maryland. Considerable interest has recently been aroused in mosquito extermination, particularly in the neighborhood of Baltimore, where favorable conditions prevail for the multiplication of these pests.

The usual line of treatment is discussed, including drainage and the use of oil and other insecticides. Brief mention is made of some of the less common substances used in destroying mosquito larvæ, including a number of proprietary remedies. The value of lime, copper sulphate, carbolic acid, creosote, and oil is also discussed.

Mosquito control, H. J. QUAYLE (*California Sta. Bul. 178*, pp. 55, figs. 35).—At the request of the Burlingame Improvement Club the station undertook an examination of a tract of land near San Francisco badly infested with mosquitoes. The species most numerous in this region was *Ochlerotatus lativittatus*, but the malaria mosquito and other species were also present. A general account is presented of the life history and migration of mosquitoes and of their connection with disease in man.

The campaign of eradication undertaken by the station consisted in the establishment of a thorough system of drainage in the salt marshes where the mosquitoes chiefly prevailed and in the use of oil on a few of the pools in fresh-water creeks. In a few instances similar work was carried out by private individuals to rid their own property of mosquitoes. The success of the

general work of eradication was very striking since during the second season the chief species of mosquito concerned was seen only in the rarest instances.

Some attention was given to the natural enemies of mosquitoes. Under the conditions which prevailed in the region in question fish could not be used advantageously, since they would not voluntarily live in the pools where the mosquitoes bred. The best species for use is apparently the stickleback. A number of insects are also mentioned as enemies of mosquitoes. Copper sulphate was used at the rate of 1 part to 1,000 in small pools, but almost without effect. The author also discourages the hope that eucalyptus will prove of any great value in the work of combating mosquitoes.

The species chiefly concerned in the mosquito campaign in question are described in all their stages and a synoptic table is presented to assist in their determination. A list is also given of the mosquitoes known to occur in California.

A preliminary report on the horseflies of Louisiana, with a discussion of remedies and natural enemies, J. S. HINE (*Crop Pest Com. La. Circ. 6, pp. 43, figs. 20*).—An investigation was made of the distribution of species of horseflies and their injurious attacks in Louisiana and other parts of the South.

The larvæ usually pass their life in the water or under ground and are, therefore, seldom observed. The species of *Chrysops* and many of those of *Tabanus* lay their eggs on plants over water, while others deposit on plants standing in wet ground. The larvæ feed on animal life of various kinds. Detailed notes are given on the life history of *Chrysops vittatus* and *Tabanus atratus*. The eggs of the latter species may be carried for many miles in water and the insect may be thus distributed far from the point of its original location.

A number of natural enemies are known to attack the horseflies, some of these insects being predaceous and others parasitic. The use of nets, oil, and insecticides of disagreeable odor may give considerable relief. Covering pools of water with kerosene, as recommended by Porchinski, is not always effective. The author recommends collecting the eggs of horseflies in localities where they are most numerous.

An annotated list is presented of all the species found in Louisiana.

Some points on the natural history of Tabanidæ, especially *Tabanus quatuornotatus*, A. LÉCAILLON (*Compt. Rend. Soc. Biol. [Paris], 60 (1906), No. 9, pp. 459, 460*).—The eggs of this species are laid during a period of 2 or 3 weeks in June. The females deposit their eggs during the middle of sunny days on dry herbage in masses of about 300 to 400. The egg masses are almost always found about 30 to 50 cm. from the ground. The larvæ, as soon as hatched, fall to the ground and penetrate into the soil.

Habits and life histories of some flies of the family Tabanidæ, J. S. HINE (*U. S. Dept. Agr., Bur. Ent. Bul. 12, pt. 2, tech. ser., pp. IV, 19-38, figs. 12*).—A detailed account is presented of the life history and habits of *Tabanus lasiophthalmus*, *T. sulcifrons*, *T. stygius*, *T. vivax*, *T. atratus*, and *Chrysops marens*. Considerable new information is given, particularly with reference to the place and method of depositing eggs. In some cases this information will be of advantage in devising practical means for controlling horseflies, but these insecticide methods have not been worked out.

British ticks, E. G. WHEELER (*Jour. Agr. Sci., 1 (1906), No. 4, pp. 400-429, pls. 6*).—The ticks of Great Britain have received but little study from a systematic standpoint, and on this account the author undertook an investigation of their life history and habits, as well as a study of their form and relationship to diseases in man and animals.

The larger part of the article is occupied with a description and classification of the ticks known to the author as occurring in Great Britain. In this

systematic arrangement the ticks are divided into 2 subfamilies, Argasinae, and Ixodinae. A considerable number of species are referred to these families as occurring in Great Britain. These include *Argas reflexus*, *Ornithodoros megnini*, *Ixodes hexagonus*, *I. ricinus*, and species of *Hyalomma*, *Hemaphysalis*, *Dermacentor*, and other genera.

How to get rid of cattle ticks. A. D. MELVIN (*U. S. Dept. Agr., Bur. Anim. Indus. Circ. 97, pp. 4, fig 1*).—Attention is called to the importance of active cooperation between local officials in various States south of the Texas fever quarantine line and the Bureau of Animal Industry for the purpose of eradicating ticks.

The eradication of ticks is believed to be possible if all suggested precautions are taken. Cattle and premises may be freed from ticks by hand picking the cattle and destroying the ticks, after which the cattle may be thoroughly greased. Infested cattle should be examined every other day, attention being given to the inside and back portion of the thighs, where the ticks are liable to be most numerous. For greasing the cattle, crude oil is recommended, or cotton-seed oil, fish oil, or lard. Where a farmer owns but a few head of cattle, the cattle may be picketed on tick-free pasture and occasionally moved, taking care to avoid these localities for 9 months thereafter.

Another method recommended is the rotation system and requires two fields. The cattle are removed from the pasture by September 1 and no animals are allowed on this pasture until March 15 of the following year. Before the cattle are allowed to go back into the original pasture they should be carefully examined for the presence of ticks.

Tests of dips as lice killers. L. L. LEWIS (*Oklahoma Sta. Bul. 72, pp. 8*).—The importance of dips in combating parasites on cattle has long been recognized, and a number of these dips were tested by the author in controlling lice and cattle ticks.

In experiments with coal-tar preparations it was found that the dips were more effective when used at temperatures of 70 to 80° F. than when applied cold. Lice were usually found dead within from 3 to 10 hours after cattle and horses were dipped. Hogs may be regularly dipped, like other animals, or a wallowing vat may be provided containing a small quantity of crude oil on the surface of the water. When this is done, the hogs keep themselves free from lice. Most of the coal-tar dips, which were tested, failed to kill the lice eggs, but kerosene emulsion was more effective in this respect.

Farmers who own but a small number of cattle will find it too expensive to construct vats especially for dipping. For these small owners it is desirable that cattle be regularly inspected about every 2 weeks from July to September, and hand treated with crude petroleum or kerosene emulsion, after the large ticks have been picked off.

The effectiveness of pasture rotation in controlling ticks is also mentioned.

The economical preparation of the sulphur-lime spray, R. W. THATCHER (*Washington Sta. Bul. 76, pp. 16*).—It is considered that the efficiency of the lime-sulphur wash is demonstrated and that at present experiments may well be directed toward the preparation of this insecticide more cheaply.

A chemical study was made of the reactions which take place in the preparations of the lime-sulphur wash according to various formulas. From this study it appears that lime-sulphur wash contains 2 soluble compounds, viz. pentasulphid and thiosulphate of calcium. The relative amounts of these 2 compounds are about the same in sprays prepared by any of the formulas and are not influenced by the presence or absence of salt. Blue vitriol, on the other hand, combines with the pentasulphid compound rendering it insoluble. Cal-

cium pentasulphid decomposes rapidly under the influence of the atmosphere after being sprayed on trees and acts energetically as an insecticide. While calcium thiosulphate decomposes more slowly, the continued action of the insecticide long after its application is apparently due to this latter compound. The author believes that the cheapest formula for the preparation of lime-sulphur wash is 1-1-4.

Spray for profit (*Oklahoma Sta. Rpt. 1906, pp. 44-54*).—Directions are given for the choice, preparation, and application of insecticides and fungicides for controlling insect pests and fungus diseases of fruits, garden vegetables, cereals, shade trees, ornamental plants, and cotton.

Silk industry (*Mo. Consular and Trade Rpts. [U. S.], 1906, No. 305, pp. 185-190*).—A statistical account is presented regarding the extent of the silk crop in various countries, including Italy, Austria, Syria, Greece, Persia, and the far Orient. Notes are also given on the methods of growing the mulberry and care of silkworms.

FOODS—HUMAN NUTRITION.

Ropiness in flour and bread and its detection and prevention, E. J. WATKINS (*Jour. Soc. Chem. Indus., 25 (1906), No. 8, pp. 350-357, pl. 1*).—Experiments are reported and data summarized regarding the causes of ropiness in bread, the ways in which ropiness is conveyed, and methods of prevention.

The trouble is produced by varieties of *Bacillus mesentericus* introduced into the dough through the flour where it sometimes occurs in large numbers, possibly coming from the bran coats. Breads containing bran and straight grade white flours are most liable to develop ropiness. The bacillus is a prolific spore former, and the spores are capable of resisting high temperatures for long periods. The development of the bacillus, when once present in the dough after bread has been made, depends partly on the reaction of the bread and partly on atmospheric conditions.

The presence of acid is unfavorable to the development of bacillus, but normal bread is only faintly acid in reaction and always insufficiently so to prevent the development and spread of ropiness. The author's experiments led to the conclusion that "the addition of a small quantity of acetic acid to the dough will effectually prevent the appearance of ropiness in the resulting bread during a much longer period than bread is usually kept. The minimum quantity of acid appears to be about 0.3 lb. per sack of flour, whilst a maximum of 0.7 lb. should not be exceeded on account of its softening action upon the gluten. When lactic acid is employed as a preventive, the minimum quantity is greater: below 0.6 lb. per sack its action is somewhat uncertain. The greater softening action of this acid upon gluten must not be lost sight of when considering the quantity to use."

"Low temperature and dryness of the bread store tend to suppress development, but the maximum temperature of 18° C. (65° F.) can not be exceeded without great risk.

"When a batch of bread is found to be ropy, all flour in stock should be at once tested, so as to locate the infected stock, and in the meantime fresh supplies of flour from a different source should be laid in.

"When the infected batch of flour has been discovered, it should be isolated, so that it can be worked up under those conditions which are most unfavorable to the development of the bacillus, i. e., the doughs being made slightly acid and the bread being quickly cooled and kept at low temperature during storage. Such flour might advantageously be kept until the colder months when the prospects of development are at a minimum.

"During the summer months the danger of purchasing rony flour may be entirely obviated by the application of the bread-tube test to a sample of the flour before buying."

The paper is followed by a discussion.

Alcohol in bread, L. SCHMELCK (*Norsk Landmandsblad*, 25 (1906), No. 9, p. 117).—Thirteen different samples of fresh bread from 10 bakeries were found to contain from 0.35 to 0.70 cc. of alcohol per 100 gm., the average amount being 0.52 cc. After 10 days about one-half of the original alcohol content was found to be present.—F. W. WOLL.

Foods and food products, whisky and other beverages, and drugs and medicines, E. F. LADD ET AL. (*North Dakota Sta. Bul.* 69, pp. 59).—The investigation reported was carried on under the provisions of the State law regulating the sale of foods, beverages, and drugs.

Foods and food products, E. F. Ladd and A. G. Nickles (pp. 3-22).—A large number of samples of jams, preserves, and jellies, canned vegetables, flavoring extracts, dairy products, meat, fish, sausages, confectionery, and other food products were examined. As shown by comparison with earlier work, the authors point out that there has been a marked decrease in the adulteration of food products, short-weight cans, and "sloppy canned goods."

Whisky, E. F. Ladd and R. E. Stallings (pp. 23-26).—Ninety-five whiskies and brandies were examined.

Drug and proprietary products, E. F. Ladd and C. H. Kimberly (pp. 27-59).—A large number of drugs and medicines were examined.

Table sirups, H. W. WILEY (*U. S. Dept. Agr. Yearbook* 1905, pp. 241-248, pls. 2).—The manufacture and food value of sirups made from maple sap, sorghum juice, and cane juice are spoken of and the superiority of natural sirups emphasized.

"The sirup made directly from the sugar cane must of necessity commend itself to the consumer in comparison with the use of molasses arising as a by-product of sugar manufacture. In the production of sugar it is an economic necessity to make a white product, and this requires the use of bleaching agents of some description. Among these sulphur is perhaps the most common. Also, in the washing of white sugar in the centrifugal, solutions of salts of tin or of indigo are often employed for giving an additional luster to the sugar. This bleaching agent must of necessity remain in the molasses, making it to this extent unsuitable for consumption. For these reasons it is evident that the production of a table sirup directly from the original source should be encouraged.

"It appears from a general survey of the data which have been collected in these experiments that it is entirely possible to supply the demand for table sirup in the United States directly from the original sources, thus removing the danger of adulteration or contamination with substances injurious to health. The general consumption of a sirup of this kind would, it is true, interfere with the industry which is engaged at the present time in making a synthetic sirup for table use from doubtful sources, but which as a rule contains more or less molasses—the by-product of sugar manufacture—and contaminated more or less with substances injurious to health. The general welfare of the farmer and consumer would therefore be promoted by the general consumption of pure sirups of the kind which have been described."

Fruit and its uses as food, C. F. LANGWORTHY (*U. S. Dept. Agr. Yearbook* 1905, pp. 307-324, fig. 1).—Among the questions considered in this general summary are color, flavor, and composition of fruits, effect of ripening on composition, the place of fruit in the diet, digestibility, and relative economy, raw and cooked fruit, and the hygiene of fruit.

"In general, it may be said that fruits are wholesome, palatable, and attractive additions to our diet, and may be readily made to furnish a considerable part of the nutrients and energy required in the daily fare. Fresh fruits are dilute foods and closely resemble green vegetables in total nutritive value, but dried fruits and many preserves, etc., are much more concentrated, comparing favorably with some of the cereals and other dry vegetable foods in the amount of total nutrients and energy which they supply per pound. The characteristic chemical constituents of fruits are carbohydrates, and so they are naturally and properly used in a well-balanced diet to supplement foods richer in protein, as cereal grains, legumes, nuts, eggs, dairy products, meats, and fish. Intelligently used, fruits are a valuable part of a well-balanced diet and may well be eaten in even larger quantities than at present."

Practical directions for preserving native fruits and vegetables, Mrs. L. H. ADAMS and E. P. SANDSTEN (*Wisconsin Sta. Bul. 136, pp. 13*).—Household methods for making jams, jellies, preserves, etc., are described, particular attention being paid to the use of native fruits. A few directions for canning vegetables are also given.

The energy required by man in the form of heat, E. MAUREL (*Compt. Rend. Soc. Biol. [Paris], 60 (1906), No. 18, pp. 863-866*).—The author briefly summarizes his own investigations and discusses other published work. His own estimate of the average amount of energy required in temperate regions in spring and fall by a man weighing 65 kg. is 2,400 calories, in summer 2,000 calories, and in winter 2,800 calories.

ANIMAL PRODUCTION.

Condimental and tonic stock foods, W. FREAR (*Pennsylvania Sta. Rpt. 1905, pp. 41-59*).—A number of condimental and tonic stock foods were examined chemically and microscopically and data summarized regarding the effect of such feeding stuffs on the rations of farm animals.

Analysis shows that these feeds are in general made up of cereals and commercial by-products and of ordinary and inexpensive drugs, such as copperas, Epsom salts, fenugreek, gentian, mustard, sulphur. The price at which they are sold is usually out of all proportion to their nutritive value and the cost of their ingredients. The data summarized show that, generally speaking, aromatic foods do not increase the flow of digestive juices nor do such feeding stuffs induce greater gains in weight or milk yield. As the author points out, animals in health rarely need these feeds while those which are sick need special treatment. "The farmer can make his own condimental mixture far more cheaply than he can buy most of the market preparations."

"It will not do, however, to infer that such mixtures are never useful, even though they do not cause the healthy animal to improve in its functional activities, do not ward off disease, nor promise cure of well-developed disorders. When used in sufficient quantity they may serve to arouse a flagging appetite, secure the consumption of food when too little variety is available, or when it is inferior in quality, or stimulate a depressed digestive system to the point of digestive activity, as cayenne rouses the adynamic stomach of the drunkard. In such cases, when salt alone has failed to correct the undesirable condition, and change of staple diet is impossible, a condimental mixture may be helpful."

Inspection of feeding stuffs (*New York State Sta. Bul. 280, pp. 233-260*).—The feeding stuffs examined during the fall of 1905 and the winter of 1905-6 under the State law included cotton-seed meal, linseed meal, gluten meal and feed, corn bran, malt sprouts, dried brewers' grains, hominy feeds, mixed wheat offals, compounded feeds, meat meals and similar animal products, compounded

poultry foods, dried molasses beet pulp, dried beet pulp, barley meal, oat by-products, and alfalfa meal.

Commercial feeding stuffs, H. J. WHEELER ET AL. (*Rhode Island Sta. Bul.* 112, pp. 77-96).—Under the provisions of the State law analyses were made of a number of samples of cotton-seed meal and feed, linseed meal (old and new process), gluten meal and feed, brewers' and distillers' grains, malt sprouts, wheat middlings, wheat bran, mixed wheat feeds, hominy meal, corn meal, horse feed, dairy and stock feeds, poultry feed, animal meal and bone, provender, alfalfa meal and molasses, alfalfa meal, sugar feed, crushed oats, dried beet pulp, oat feeds, and proprietary feeds.

"Consumers are again cautioned to beware of ground feeds other than genuine corn meal, wheat middlings, bran, and mixtures of the last two, unless they are guaranteed. The law does not require that these be sold under a guaranty. Consumers are equally cautioned to read the guaranties, for cotton-seed meal containing only about 23 to 24 per cent of protein is guaranteed, as is also that containing from 38 to 43 per cent. Adulterated 'mixed feed' is also on the market containing only from 12 to 13 per cent protein, while the genuine mixed feed, composed of pure wheat bran and middlings, usually contains from 15 to 18 per cent of protein."

Inspection of concentrated commercial feeding stuffs, F. W. WOLL and G. A. OLSON (*Wisconsin Sta. Rpt.* 1905, pp. 374-377).—A table is given showing the proportions of protein and fat in 61 brands of commercial feeding stuffs licensed for sale in the State.

Coefficients of digestibility of American feed stuffs. Experiments made in the United States, J. B. LINDSEY and P. H. SMITH (*Massachusetts Sta. Rpt.* 1905, pp. 224-248).—A summary of digestion experiments which have been made with farm animals at the experiment stations in the United States.

Analyses of oats, C. F. JURITZ (*Rpt. Senior Anal. Cape Good Hope, 1905*, pp. 34-36).—Ash, lime, and phosphoric acid in original material, and lime, phosphoric acid, and carbon and silica in ash are reported for samples of oats from Algeria, South America, Canada, Australia, and Cape of Good Hope.

These analyses were made in view of a complaint that the colonial oats were unsuited for feeding horses on account of a deficiency of lime. The analyses show no foundation for this belief. The percentage of lime in the 5 samples of oats varied from 0.054 to 0.147, the phosphoric acid from 0.441 to 0.734.

Do white moss and white-moss peat possess any feeding value? H. VOX FELTZEN (*Svenska Mosskulturför. Tidskr.*, 20 (1906), No. 1, pp. 77-79).—The author summarizes earlier investigations in regard to the feeding value of peat and gives the following analysis of dry sphagnum moss (*Sphagnum cuspidatum*), calculated to a dry-matter basis: Protein 6.62 per cent, fat 0.99 per cent, nitrogen-free extract 65.51 per cent, crude fiber 23.89 per cent, pentosans 15.70 per cent, and ash 2.99 per cent. The amid nitrogen was 20.8 per cent, the digestible albuminoid nitrogen 6.6 per cent, and the indigestible nitrogen (nuclein) 72.6 per cent of the total nitrogen. Carbohydrates yielding mannose, galactose, dextrose, levulose, and pentoses on hydrolysis were found in sphagnum and sphagnum peat, but quantitative determinations were not made of these polysaccharids. The feeding value of the sphagnum moss is shown to be very low.—F. W. WOLL.

Speltz and millet for the production of baby beef, J. W. WILSON and H. G. SKINNER (*South Dakota Sta. Bul.* 97, pp. 61-74, figs. 8).—The relative value of speltz, oats, millet, and corn for calves raised on separator milk and for yearlings on pasture was studied, as well as the practicability of fattening yearlings for the production of baby beef. Hay was fed in addition to the grain.

Each lot contained 2 steers and a spayed heifer and the test as a whole

covered 431 days. The gain ranged from 1.47 lbs. per head on millet to 1.84 lbs. on corn.

"The best gains were made with the ground millet during the fattening period, being 1.76 lbs. per head daily, while the lot fed on corn meal produced 2.8 lbs. per head daily during this period. . . .

"Speltz produces a hard fat, about the same as oats; and as good a quality of meat as corn. . . .

"Fat made by Black Veronesh millet seed was much softer to the touch than that made by either corn, oats, or speltz. When fed as a fattening ration, this variety of millet seed seems to be more like oats than corn. This is shown by the fact that the lot fed on oats required practically the same quantity of hay per pound of gain as did the lot fed on millet. . . .

"It required 0.37 of a pound more of ground millet seed than it did ground corn to produce a pound of gain on calves fattened for baby beef. . . .

"With the exception of the speltz lot, the spayed heifers brought the same price as the steers. . . .

"Ground oats proved to be a profitable feed for the production of baby beef. From a careful examination of the lots before shipping these steers were nearly as fat as those fed on corn. . . .

"When the calves were fed in lots on the same kind of grain from birth to maturity those which received the most highly carbonaceous grain produced the largest per cent of dressed meat. . . .

"In feeding calves for the production of baby beef the following prices were obtained per bushel for grains used: Corn 47 cts., oats 26 cts., millet 38 cts., and speltz 33 cts."

Digestion experiments with wethers. Alfalfa and native hay, H. G. KNIGHT, F. E. HEPNER, and G. E. MORTON (Wyoming Sta. Bul. 69, pp. 42, figs. 4).—The digestion experiments reported gave the following average results:

Digestibility of alfalfa and native hay—Experiments with wethers.

Kind of feed.	Number of tests.	Dry mat-ter.	Protein	Fat.	Nitrogen-free extract.	Crude fiber.	Ash.
		<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>
Second cutting alfalfa.....	5	64.50	79.63	43.32	46.23	75.53	55.35
First cutting alfalfa.....	2	60.39	76.33	35.29	44.37	71.80	45.85
Native hay.....	2	64.64	56.28	41.59	69.96	68.04	30.63
Native hay (sedges, rushes, grasses).	1	63.21	59.06	62.87	65.09	64.12	53.04

"Wyoming alfalfa hay runs higher in crude fiber and crude protein than the average. The digestion coefficients of the crude protein is also high. The nutritive ratio of first-cutting alfalfa is 1:3.19; second cutting for both years, 1:3.68. Second-cutting alfalfa is apparently a better feed. . . .

"The native hays of Wyoming are better and more nutritious than timothy grown in the Eastern States."

Analyses were made of the above-mentioned feeding stuffs, and in view of the fact that alfalfa is more difficult to cure than some other hays in wet seasons detailed studies were also made of the water extract of alfalfa and native hay as it was thought that this material might bear some relation to the difficulty experienced in curing alfalfa hay, particularly in damp weather. The total water extract of alfalfa hay on an average amounted to 27.43 per cent, of which 5.93 per cent was ash and 21.50 per cent organic matter. In the case of native hay (western wheat grass) the total water extract was 22.23 per cent, the ash and organic matter being, respectively, 2.58 and 19.65 per cent. In the case of

native hay (wire grass) the total water extract was 18.84 per cent and the ash and organic matter 3.79 and 15.05 per cent, respectively.

"Such a large percentage of soluble nutritious material as is present in alfalfa make it an excellent subject for bacterial attack and subsequent fermentation when dampening during the process of drying. This may be one important reason for the ease with which alfalfa discolors and ferments, compared with other well-known and much-used forage."

The value of various grain rations for fattening wethers, G. C. HUMPHREY and F. KLEINHENZ (*Wisconsin Sta. Rpt. 1905, pp. 39-52, figs. 4*).—Three series of tests are reported, made in each case with 4 lots of 4 animals. In the first test lot 1 was fed cracked corn and whole oats 1:1; lot 2, cracked peas and whole oats 1:1; lot 3, cracked wheat and whole oats 1:1; and lot 4, whole oats. In the other tests the rations were the same, except that barley was substituted for cracked wheat with lot 3. In all cases the grain was supplemented by pasture, hay, cabbage, and roots. The tests have covered 14-18 weeks.

Considering the series as a whole, the average weekly gain on corn and oats was 2.7 lbs. per head, on peas and oats 2.53 lbs., on barley and oats 2.32 lbs. (2 tests only), and on whole oats 2.34 lbs., the cost of food per pound of gain ranging from 4.5 cts. on corn and oats to 6.69 cts. on peas and oats. In the first year's trial the weekly gain on wheat and oats was 2.61 lbs. per head and the cost of food per pound of gain 5.26 cts. The lots were each year exhibited at the International Stock Show and were awarded a number of prizes.

"The results of this experiment indicate that a mixture of cracked corn and whole oats is the most economical feed and the best for producing mutton of the highest quality.

"The oat ration seems the best for producing firm handling quality without softness or overripeness. Peas and oats are also highly recommended for this purpose, but they proved expensive. Barley and oats gave results that warrant further trial. The single year's test of wheat and oats was not satisfactory."

The production of winter lambs, G. C. HUMPHREY and F. KLEINHENZ (*Wisconsin Sta. Rpt. 1905, pp. 53-61, figs. 4*).—Six grade ewes, 4 of which showed Dorset blood, pastured during the summer and bred to a Dorset ram, gave birth to 7 lambs. At lambing time the ewes were kept in a warm pen. They were fed bran, oats, and oil meal 20:10:1 with clover and alfalfa hay, cabbage, roots, and silage.

The lambs were fed alfalfa hay and a mixture of bran, oats, corn meal, and oil meal 4:2:2:1. The average weight of the lambs at birth was 10.7 lbs., the average age when marketed 75.2 days, and average weight before shipping 60.4 lbs. The calculated net profit per lamb was \$6.43.

The production of satisfactory winter lambs "requires good housing and a knowledge of feeding and management that will insure rapid development of the lambs from birth until placed upon the market. Such knowledge can be acquired only by experience and studying the conditions and successful operations of others engaged in this occupation."

The trial reported the authors consider successful. "The lambs were all saved, they developed good form and quality, and commanded a good price. The cost of feed was comparatively small, though the quantity and quality was all that could be desired. The ewes were good milkers, and had there been more twins produced, as was the case in former years, the profits would have been still greater.

"In selecting ewes for winter lambs, size, prolificacy, and good milking qualities are essential, as the gains made by the lambs are largely dependent upon

the milk supplied. Dorset ewes are recommended for this purpose, since they breed early, are prolific, and give large quantities of milk rich in fat."

Exercise v. confinement in winter for young wethers, G. C. HUMPHREY and F. KLEINHEINZ (*Wisconsin Sta. Rpt. 1905, pp. 62-64*).—In the test reported, which covered 14 weeks, 14 lambs given outdoor exercise made an average weekly gain of 0.94 lb. per head and required 7.07 lbs. of grain and 27.02 lbs. of coarse fodder per pound of gain. In the case of a similar lot fed on the second floor of the sheep barn and given no exercise the gain was 1.04 lbs. per head per week, the grain eaten per pound of gain 6.69 lbs., and the coarse fodder 25.57 lbs. The cost of feed per pound of gain in the 2 cases was 12.7 and 12 cts., respectively. Both lots were fed similar rations of mixed hay, mangels, and corn, oats, and bran 1:2:1.

Summarizing this and earlier tests (E. S. R., 16, p. 807), the authors state that the average weekly gain per lamb with exercise has been 1.2 lbs. and without exercise 1.3 lbs., and the cost of gain in the 2 cases 12 and 11 cts.

"The results of these 3 trials lead one to believe that for feeding growing wethers, close confinement in pens which are dry, with fresh air and light, is equal to, if not somewhat better, than allowing plenty of exercise. It is believed that there is much space in the farm buildings throughout the State which could be utilized for feeding a greater or less number of wethers. No better class of stock can be recommended for converting farm grains and roughage into cash and fertilizers than sheep. The farmer who has feed and unoccupied space in barn driveways, emptied mows, or stair lofts, can utilize the same to a good advantage by feeding sheep."

The value of soy beans in grain rations for lambs, G. C. HUMPHREY and F. KLEINHEINZ (*Wisconsin Sta. Rpt. 1905, pp. 65-68*).—Continuing earlier work (E. S. R., 16, p. 807), a ration of soy beans and shelled corn 1:1 was compared with a similar mixture of oats and shelled corn.

The 9 lambs fed the soy-bean ration made a total gain of 119 lbs. during the 12 weeks of the test as compared with 71 lbs. in the case of the corn and oats ration. The grain eaten per pound of gain in the 2 cases was 6.35 and 10.62 lbs., respectively, and the coarse fodder 10.51 and 16.65 lbs. The lambs fed soy beans produced 95.1 lbs. of wool and those fed oats 81.3 lbs.

From this and earlier work the authors conclude "that soy beans are an economical supplement to corn for gains with sheep both in body weight and wool production. The increase in wool produced was 13.8 lbs., which sold for 30 cts. per pound, increasing the profits by \$4.14."

The feeding stuffs used were analyzed.

Summary of pig feeding experiments, F. B. LINFIELD (*Utah Sta. Bul. 94, pp. 27-62*).—Feeding tests with pigs are reported and general deductions are drawn from the investigations which have been carried on since 1890 at the station.

In continuation of earlier work (E. S. R., 10, p. 986) the value of dairy by-products for fattening was studied. In a test made with 2 lots of 3 pigs each and 1 lot of 4 pigs the average daily gain in 76 days on grain alone was 0.67 lb. per head; on grain and skim milk 1:10, 1.43 lbs., and on grain and skim milk 1:5, 1.62 lbs.

In the second test, which covered 87 days, 8 lots of 3 pigs each were used and skim milk or whey alone, grain alone, and grain and skim milk or whey in large and small amounts were tested. Three lots were fed in pens, the others on pasture. The gain on pasture ranged from 0.67 lb. per head on skim milk only to 1.25 lbs. on a full ration of grain and skim milk. In pens the gain ranged from 0.75 lb. on grain alone to 1.35 lbs. on a full ration of grain and skim milk.

Considering both tests the dry matter eaten per pound of gain ranged from 2.03 lbs. with pastured pigs fed skim milk or whey alone to 4.45 lbs. with pigs fed grain alone. In general, the lots fed skim milk and grain made larger gains than those on skim milk alone or grain alone and those fed in pens more than similar lots in pasture.

The feeding was continued for 16 days with 4 of the lots used in the second test to secure data regarding the influence of previous methods of feeding on subsequent gains. All the lots were fed a full-grain ration with skim milk and whey. The lot previously fed a half-grain ration on pasture made the most rapid gain, 2.06 lbs. per day, "and made the gains at a smaller cost in grain for each pound of gain." The lot previously fed skim milk alone on pasturage made the smallest gain, 1.77 lbs. per head per day, and made the gains least economically.

"Skim milk alone would appear not to be so good a preliminary feed for fattening hogs, as the gains were not so rapid nor so economical in any of the stages of fattening as when the hogs were fed a half-grain ration on pasture."

To test the value of whole milk 3 young pigs averaging 41 lbs. each were fed this material for 50 days, some grain being given the last week of the period. The average gain was 0.867 lb. each, 13.25 lbs. of milk and 0.18 lb. of grain being required per pound of gain. After an interval of 13 days on pasture the feeding was resumed and the pigs were given milk and grain 3:1 for 30 days. The average daily gain was 1.89 lbs. each, 5.12 lbs of milk and 1.71 lbs of grain being required per pound of gain. The author calculates that when fed with grain whole milk has twice as great a value as when fed alone.

"Compared with trials with skim milk, 100 lbs. of whole milk displaces on the average about twice as much grain as 100 lbs. of skim milk, or, in other words, 50 lbs. of whole milk is equal to 100 lbs. of skim milk as a feed for hogs when both are fed with grain as a part of the ration.

"The above is, of course, the result of but one trial and may be modified by future tests."

The general conclusions regarding skim milk, which were drawn from the station experiments as a whole, follow:

"For the most rapid gains, and therefore the greatest economy in time and labor, a ration of grain and skim milk in the proportion of 1 lb. of grain to 5 of skim milk for young animals and 1 to 3 for older animals has given us the best results. When the animals were fed in pens we got the most rapid gains, but when on pasture slightly the most economic gains. Thus whether to feed in pasture or in pens is a matter to be determined more by the circumstances of the feeder than by any great advantage in either method.

"When the price of grain is high, slower but more economical gains are made by feeding a small quantity of grain and giving all the milk the hogs will eat. When so fed considerably better results are obtained by feeding on pasture than in pens.

"Hogs will gain fairly well on a ration of skim milk alone, but we have found it difficult to keep them in good health when so fed in pens. When this ration is fed on pasture the hogs keep in better health, gain a little more rapidly, and make more economical gains. Such a ration is not to be recommended when grain can be obtained at a reasonable price."

As regards the value of different grains, the conclusion drawn from the Utah work is that wheat has proved the most effective as regards both rapidity and economy of gain. Corn meal and barley have proved to have much the same value, barley being somewhat superior on the basis of weight of the pigs. It also appears that the best results were obtained, as regards both the rapidity and economy of gain, when pigs were given grass, or allowed to run

on pasture, or when fed skim milk with a grain ration. In the winter season pigs should be fed in a dry pen, but they will make faster and more economical gains if they have access to a little alfalfa hay.

Whole corn compared with corn meal for fattening pigs, W. A. HENRY (*Wisconsin Sta. Rpt. 1905, pp. 16-20*).—Five pigs fed equal parts of heavy wheat middlings and corn meal mixed to a slop with water gained 106 lbs. in 14 weeks, 5.77 lbs. of grain being required per pound of gain, as compared with a gain of 123.6 lbs. per head in the case of a similar lot fed a mixture of equal parts of dry wheat middlings and shelled corn, 5.23 lbs. of grain being required per pound of gain.

Summarizing the present test and earlier investigations (E. S. R., 16, p. 808), the average gain on the dry ration has been 96.8 lbs. per head and the feed eaten per pound of gain 5.18 lbs. Similar values on the ground corn and wheat middlings ration have been 116.9 lbs. and 4.88 lbs. Grinding the corn, according to the author, effected a saving of 5.7 per cent. The advisability of grinding is determined by the price of corn and the cost of grinding.

“When corn is worth only 25 cts. per bushel the saving from grinding amounts to only 1.4 cts., not enough to pay for the grinding unless cheap power is available. As corn advances in price it will be noticed that the saving per bushel increases practically three-tenths of a cent with each 5 cts. advance in the price of corn. Should the price of corn be as high as 75 cts. per bushel the saving by grinding would amount to a little over 4 cts. per bushel.”

Soy beans v. wheat middlings as a supplement to corn meal for growing and fattening pigs, G. C. HUMPHREY (*Wisconsin Sta. Rpt. 1905, pp. 21-30, pl. 1, figs. 2*).—In continuing the work of the previous year (E. S. R., 16, p. 809), 5 pigs were fed corn meal and soy-bean meal 2:1, while a similar lot was fed corn meal and wheat middlings in the same proportion, both lots being given some skim milk.

During the 27 weeks of the test the average gain per head on the soy bean meal ration was 1.37 lbs. and on the wheat middlings ration 1.24 lbs., the grain consumed per pound of gain in the 2 cases being 3.75 and 4.14 lbs., and the skim milk 3.9 and 4.31 lbs. As shown by slaughter tests with 2 animals from each lot, the dressed weight on soy beans was 82.85 per cent of the live weight and on wheat middlings 84 per cent. Other data are recorded.

The conclusions drawn from the tests were in effect as follows: Soy beans make an excellent supplement to corn meal for growing and fattening pigs and are a little over 10 per cent more valuable than wheat middlings for pork production. In feeding equal amounts of the two rations, the soy beans and corn meal supply a slightly higher percentage of dry matter and digestible matter than the wheat middlings and corn meal. For firmness, fine grain and texture of flesh, and even distribution of fat and lean, the ration of wheat middlings and corn meal is superior to that of soy beans and corn meal.

Feeding cotton-seed meal to swine, J. G. FULLER (*Wisconsin Sta. Rpt. 1905, pp. 31-36*).—In the first trial reported a ration of equal parts of corn meal and cotton-seed meal mixed to a thick slop was fed to a lot of 5 pigs, while a similar lot was fed the same mixture soaked in water for 48 hours so that it had become thoroughly soured.

At first the gains were satisfactory, but about the middle of the 10 weeks' test the pigs began to lose their appetite and for the last 4 weeks they lost flesh and 2 in each lot died late in the test or after it closed. The total gain on the fresh cotton-seed ration was 131 lbs. and on the sour cotton-seed ration 139 lbs.

In a second test, made under practically the same conditions and covering 6 weeks, the total gain made by 5 pigs was 41 lbs. on fresh cotton-seed meal and 39 lbs. on sour cotton-seed meal. In this test also the gains were satisfactory

until the sixth week, when 1 pig fed the fermented cotton seed died and the condition of the remainder was such that the experiment had to be discontinued. Two pigs died a few days afterwards. In this and the preceding test post mortem examination showed that the vital organs were affected, as has been noted in other experiments with cotton-seed meal.

In the third trial, which was made with 2 lots of 7 pigs each, the ration consisted of nine-tenths corn meal and one-tenth cotton-seed meal fed in comparison with corn meal and wheat middlings 1:1, the grain in both cases being supplemented by skim milk. In 9 weeks the pigs fed cotton-seed meal gained 352 lbs. and those fed wheat middlings 169 lbs. In the fifth week of the test one of the pigs fed cotton-seed meal died, but post-mortem examination showed none of the conditions present in the other trials.

"From these trials there is no encouragement for the farmer, under our present knowledge, to feed cotton-seed meal to swine. While it is used quite generally for dairy cows, and, in certain localities, is fed in large quantities to fattening cattle, it may prove fatal to swine when fed even in relatively small quantities."

Middlings and ground barley v. middlings and corn meal as a grain ration for young sows, J. G. FULLER (*Wisconsin Sta. Rpt. 1905, pp. 37, 38*).—Six young sows fed equal parts of wheat middlings and ground barley mixed with skim milk made a total gain of 643 lbs. in 15 weeks, the total amount of grain and skim milk eaten being 3,370 and 4,008 lbs., respectively. An equal number of sows fed wheat middlings and corn meal 1:1 with skim milk gained 730 lbs. and consumed a total of 3,342 lbs. of grain and 4,008 lbs. of milk.

The inferior gain made on the ground-barley ration was attributed to the fact that one of the pigs lost weight rapidly toward the close of the test. With this exception the animals in both lots were in excellent condition at the close of the trial.

The location, construction, and operation of hog houses, W. DIETRICH (*Illinois Sta. Bul. 109, pp. 286-302, figs. 6*).—The location and construction of hog houses are discussed and methods of operating a hog house planned and built at the station, which meets the requirements indicated, are given.

According to the author's summary—

"A hog house should be located so that it is well drained, well lighted, and gives access to pasture, good shade, pure running water, and clean mud wallows.

"The two principal kinds of hog houses are the individual houses and the large houses with individual pens. Each has its points of advantage.

"For sanitation the building should be constructed so that it is dry, ventilated, free from dust and drafts and so that the direct rays of the sun fall upon the floor of the pens at the time the winter crop of pigs is farrowed. These rays should also be excluded during the summer.

"The building should be made serviceable by being built so that it can be used every day in the year and be arranged so that the largest amount of work may be performed with the smallest amount of labor.

"For large houses gates and partitions made of wire are best because they do not obstruct the light and heat rays from the sun, do not hide the pigs from view of the attendant, nor from each other, and do not furnish lodgment for disease germs.

"The large hog house is operated so that two litters per year are farrowed and grown for market and so that the pigs are put on the market at the most favorable season.

The fecundity of Poland China and Duroc Jersey sows, G. M. RÖMEL (*U. S. Dept. Agr., Bur. Anim. Indus. Circ. 95, pp. 12*).—The examination of Poland China record books indicates an increase of 0.48 per litter for 20

years, an increase which the author points out would not be of great importance when hogs are raised for the butchers' trade, but which represents a very substantial increase to the value of the breed considered from a breeding standpoint.

Considering American and Ohio Poland China records for 1898 to 1902, the average sized litter is 7.52. The records for Duroc Jersey sows showed differences too small to have any particular importance as regards increase or decrease in fecundity. The average size of litters for 10 years covered by the records consulted is 9.26. These results confirm common observation—that Duroc sows are more prolific than Poland Chinas."

Laws pertaining to horse breeding in Wisconsin (*Wisconsin Sta. Rpt. 1905, pp. 379-382*).—The text of the laws enacted April 22, 1905, regulating the public service of stallions in Wisconsin is quoted.

Ostrich farming in Arizona, W. PICKRELL (*U. S. Dept. Agr. Yearbook 1905, pp. 399-406, pls. 3*).—An historical account is given of ostrich farming in Arizona and general problems concerned with ostrich raising are spoken of, such as egg laying and incubation, feeding and care of the chicks, plucking and sorting feathers, handling and feeding ostriches, and the possible profits of the ostrich industry.

Young ostriches, according to the author, are usually kept in troops of 25 to 50, and when a year old the males should be separated from the females. When 3 years old the birds should be paired and each pair placed in a separate inclosure. If they are to graze on alfalfa or other green feed, the inclosure should be large enough to supply them all they need. If given dry feed, the inclosure need only be large enough for exercise.

"One of the very best feeds for ostriches is alfalfa. One acre of good alfalfa in Arizona will maintain 4 ostriches without their receiving any additional feed. When pastured or fed on green alfalfa they are always healthy. . . .

"Ostriches thrive well on any tender green forage, and they prefer the kind they have been taught to eat. Birds fed on hay, when turned out, often refuse to eat grass until they become very hungry.

"For dry feed, alfalfa or clover hay cut up, mixed with bran, and moistened is excellent. An ostrich will consume about 3 lbs. of hay and 1 lb. of bran daily. They should have gravel and broken bone at all times. Occasionally an ostrich will get a piece of bone lodged in its throat. In such case, if the bone can not be worked up or down by external manipulation, the throat may be cut, the bone removed, and the incision sewed up. It will heal very quickly.

"Ostriches may be fed any kind of grain—corn, wheat, barley, oats, or peas. Some farmers feed a little grain while the birds are nesting. Ordinarily, however, if ostriches are in good flesh and have plenty of good green feed they need no grain. Besides, if fed much grain they are liable to become cross and hard to manage."

As regards ostrich farming as a profitable industry, the author points out that an acre of alfalfa will keep 4 birds, yielding annually 1.5 lbs. of feathers with an average value of \$20 per pound, and 36 to 90 eggs, weighing 3.5 lbs., which may be used for incubation or for food, and if the ostriches are sold, which is rarely the case, the price ranges from \$100 for 6 months old birds to \$800 or more per pair at 4 years.

Ostriches are too valuable for food purposes at present, but it is pointed out that the flesh is said to be much relished by those who have eaten it, while the eggs are palatable when made into omelets, etc.

Poultry experiments, W. P. BROOKS, F. R. CHURCH, and S. B. HASKELL (*Massachusetts Sta. Rpt. 1905, pp. 43-46*).—Wheat and corn supplemented by animal meal were compared with 2 lots, the ration in both cases being charac-

terized by high fat and ash content and a low fiber content. Sufficient corn oil was added to the wheat ration to make the total fat in the 2 rations practically the same.

In the first period, March 2 to May 12, the relative egg production on wheat was at the rate of 39 eggs and on corn 45 eggs per day per 100 hens, the cost per egg being 1.036 and 0.749 cts., respectively.

In the second period, May 13 to September 23, the egg production on wheat was at the rate of 31 eggs and on corn 41 eggs per day per 100 hens, the cost per egg being 0.895 and 0.703 ct., respectively. These results, it is pointed out, are in accord with those of earlier years (E. S. R., 17, p. 283).

In the second test wheat and corn were compared, milk albumen being used as a source of animal food, and corn oil being added to the wheat ration to make the fat content of the 2 rations alike. Both rations were characterized by relatively high ash content and low fiber content and by a fat content lower than in the first test.

In the spring period the egg production was at the rate of 41 eggs per day per 100 hens on wheat and 39 eggs on corn. Similar values for the summer period were 35 eggs on wheat and 31 eggs on corn. The cost of food per egg in the spring period on wheat was 1 ct. and for the summer period 0.845 ct., and on corn 0.942 and 0.871 ct., respectively.

The experiment indicates "that, unless the fat content of the ration is relatively high, the more starchy foods are not sufficient to produce a satisfactory egg yield, and the product falls below that obtained from feeding a ration higher in protein."

In the third test the rations were characterized by low protein and high fat and ash content, the grains selected for comparison being oats with oat feed and rice. Beef scraps were used to supply animal food. For the spring period the average egg production for the oat ration (high fiber content) was 40 eggs per day per 100 hens and for the rice ration (low fiber) 42 eggs. Similar values for the summer period were 38 and 46 eggs. The cost of food per egg on the oat ration was 1.019 cts. for the first period and 0.935 ct. for the second period, and for the rice ration 1.103 and 1.048 cts., respectively.

As heretofore (E. S. R., 17, p. 283), the rice ration gave a very satisfactory egg yield, but it is so high in price that it can not be fed economically. It was selected for experimental purposes on account of its low fiber content, and results indicate very clearly that a small amount of fiber is unfavorable.

The nutritive ratios in the food combinations used ranged from 1:4.03 in one of the wheat rations to 1:6.69 in one of the corn rations. "Our experiments clearly do not support the view that a narrow nutritive ratio is essential to good egg production."

Raising chicks artificially, J. H. STEWART and H. ATWOOD (*West Virginia Sta. Bul. 98, pp. 171-181, pls. 4*).—Much attention has been devoted at the station to the incubation and brooding of chickens, and on the basis of the data secured and other available information directions are given for managing incubators, brooding chicks, feeding, care, and similar topics.

The necessity for a satisfactory incubator, which is durable, is pointed out, and the authors are in favor of hot-air machines because they are less troublesome to manage.

"It is a very bad plan to use eggs for incubation which have been produced by hens that have been fed heavily during the winter for egg production. Under these conditions the vigor of the hens, when spring comes, is apt to be reduced, and even though the eggs may hatch fairly well, the chicks are apt to be weak and puny. The breeding stock must be vigorous in order to produce the right sort of eggs. . . ."

"During the first two or three days after the chicks are hatched they require warmth and the opportunity to gain strength rather than to receive food. They should be supplied with water, however, and it will do no harm if they have a little fine chick grit at which to peck. . . .

"During the past few years we have found that by raising chickens in a piped brooder house and then transferring them to colony houses the labor of attending to individual brooders is not only avoided, but the chicks have been healthier and more of them have been raised to maturity. Outdoor brooders have not been successful. They are difficult to attend to in stormy weather, and in a few years become old and out of repair, and if indoor brooders are to be used on any considerable scale it seems wiser to construct a piped brooder house kept warm by a heater burning coal or gas rather than to bother with a number of individual lamps, each of which is almost of as much trouble to attend as the large heater."

The value of skim milk for laying hens, J. H. STEWART and H. ATWOOD (*West Virginia Sta. Bul. 102, pp. 265-277*).—Two tests are reported of the value of skim milk *v.* water for wetting a feed mash.

In the first test, which covered 122 days, 22 hens fed skim milk laid 1,244 eggs as compared with 996 eggs laid by the 22 hens fed mash wet with water.

In the first period of the second test 60 hens fed the skim-milk ration laid 862 eggs in 37 days as compared with 632 eggs laid by a similar lot fed no skim milk. In the second period, which covered 56 days, the rations were reversed. The chickens fed skim milk laid 1,220 eggs as compared with 978 in the case of the lot fed no skim milk. In every case the pens contained 1 cock to 10 hens.

"In both experiments more eggs were produced when skim milk was substituted for water for moistening the mash.

"Under the conditions prevailing in these experiments and with eggs selling for 20 or 25 cts. per dozen the skim milk used for moistening the mash had a feeding value of from $1\frac{1}{2}$ to 2 cts. per quart.

"In these trials 802 qts. of skim milk were fed, resulting in an increase in the egg production of 702 eggs."

A comparison of White Leghorn and mongrel hens for winter egg production showed that under similar conditions 50 mongrels in a year produced 4,807 eggs as compared with 5,824 eggs laid by the blooded stock. Both lots were handled alike, receiving the ordinary care and attention which would be given on an average farm. In addition to the skim milk used to moisten the mash the Leghorns consumed 61 lbs. of food costing \$5.3 cts. as compared with 66.8 lbs. of the same materials costing 92.1 cts. which was consumed by the mongrels. The calculated profit from the eggs was \$1.39 for the Leghorns and 86 cts. for the mongrels. "The mongrels gained in weight 1 lb. per head more than the Leghorns. If this increase in weight is taken into consideration, then the Leghorns gave a profit of 40 cts. per hen more than the mongrels."

The highest prices for fresh eggs are usually obtained from November to March. "During these 4 months the mongrels laid only 364 eggs and the Leghorns 1,029, or practically three times as many."

In the authors' opinion the experimental data recorded in this test furnish some evidence regarding the error incident to experiments of this character.

"These results indicate that in poultry experiments of this class in which 25 or more fowls are used in each lot the results of a 6 months' trial will be practically as accurate and reliable as though the test were continued for an entire year. Also that the error, almost inseparably connected with experiments of this nature, should not exceed 3 per cent after the test has been conducted for 4 or 5 months."

Inheritance in poultry, C. B. DAVENPORT (*Washington: Carnegie Institution of Washington, 1906, pp. 136, pls. 17, figs. 4*).—An elaborate series of experiments in poultry breeding carried on at the Cold Spring Harbor Station for Experimental Evolution led to a number of general conclusions from which the following are quoted:

"Poultry exhibit numerous unit characteristics which do not blend in hybridization, but are inherited in alternative fashion. The unit characters are not immutable things in hybrids, but subject to modification—perhaps permanent—by interaction of the alternative characters.

"Although the great majority of characteristics of poultry are inherited alternatively, yet a few cases of color characters show a particulate inheritance. The comparative rarity of blending of characters makes it easier to see how new characters will not be 'swamped by intercrossing with the parent form.'

"Specific and varietal characteristics in de Vries's sense are not inherited in a markedly different fashion, although in 2 cases progressive variants do not Mendelize typically.

"The patent characteristic is usually dominant over its latent allelomorph. Old and new characteristics are equally dominant. Dominance and recessiveness of characteristics are not always accompaniments of their segregation in the germ cells; both, moreover, are frequently incomplete. Dominance is usually, but not always, independent of the races crossed. Prepotency is as truly important in inheritance as dominance. . . .

"Reciprocal crosses exhibit differences due to the fact that the father and the mother transmit different kinds of characteristics. . . .

"The proportion of the 2 sexes in hybrids is normal. With few exceptions correlated characteristics easily separate as a result of hybridization so that any conceivable combination may be effected."

DAIRY FARMING—DAIRYING.

Feeding experiments with milch cows, J. H. STEWART and H. ATWOOD (*West Virginia Sta. Bul. 106, pp. 335-345, pl. 1, fig. 1*).—Two experiments are reported in which the economy of feeding more silage and hay and less grain was studied. The first test included 8 cows and lasted 20 days, and the second, 7 cows and lasted 45 days.

"Realizing that definite conclusions can not be drawn in feeding trials of this nature from 2 short tests, yet these experiments indicate that when a dairyman has plenty of good corn silage it will not be wise to feed more than 5 or 6 lbs. per day of a mixture of cotton-seed meal and wheat bran to cows of the average size employed in this test."

Dried-beet pulp or molasses-beet pulp for dairy cows, F. W. WOLL and G. C. HUMPHREY (*Wisconsin Sta. Rpt. 1905, pp. 108-117*).—Brief notes are given on the production of these 2 feeding stuffs and feeding experiments with cows are reported. The ration used for comparison consisted of 5 lbs. of hay, 35 to 40 lbs. of silage, and about 8 lbs. of a grain mixture consisting of wheat bran, distillers' grains, and cotton-seed meal in the proportion of 2:2:1. Dried-beet pulp or molasses-beet pulp was substituted for the wheat bran in the ratio of 3:2 by weight. Two tests were made, the first including 15 cows and the second 6.

When wheat bran was replaced by dried-beet pulp in the proportion indicated there was no appreciable difference in the effect of the 2 rations. Molasses-beet pulp substituted in the same manner produced, however, about 12 per cent more milk and 8 per cent more butter fat. Beet pulp showed a tendency

to decrease the fat content of the milk. The results, therefore, indicate that when wheat bran is valued at \$18 a ton, dried-beet pulp is not worth over \$12 and molasses-beet pulp over \$13 a ton.

Bibby's dairy cake, J. B. LINDSEY (*Massachusetts Sta. Rpt. 1905*, pp. 79-85).—Digestion experiments with sheep and feeding experiments with cows were made to determine the value of this proprietary feeding stuff which is said to be composed of cotton seed, carob beans, corn, wheat, fennugreek, salt, etc. The material was found to resemble in composition and digestibility standard wheat middlings. At prevailing market prices it is not regarded as an economical feeding stuff.

It is believed that farmers will do well to produce their hay, silage, and corn meal and purchase only those feeding stuffs that are rich in protein, such as cotton-seed meal, gluten feed, distillers' grains, brewers' grains, wheat middlings, and bran.

Concerning wheat bran, J. B. LINDSEY (*Massachusetts Sta. Rpt. 1905*, pp. 94-114).—Notes are given on the composition, digestibility, and fertilizing ingredients of wheat bran as compared with other concentrated feeding stuffs, and 2 feeding experiments with cows are reported. The roughage in the 2 rations compared consisted of hay and silage and the grain feed of cotton-seed meal and flour middlings. To this was added either bran or silage with corn meal or corn-and-cob meal. In one of the experiments the results were slightly in favor of the bran ration, while in the other the so-called silage ration gave the best results.

The author concludes that for small herds the quantity of purchased grain may be reduced to 3 to 4 lbs. daily by substituting home-grown corn in place of wheat bran. It is suggested that the grain mixture may consist of 1½ lbs. cotton-seed meal, 2 lbs. flour middlings, and 2½ to 3 lbs. corn meal or corn-and-cob meal. Malt sprouts may be substituted for the wheat, oats, or rye middlings. Where the feeding can not be closely supervised and where it is desired to feed more than 5 to 7 lbs. of grain daily, it is considered advisable that the grain mixtures should consist of one-third to one-half of wheat bran.

The addition of salt to the ration of dairy cows, S. M. BABCOCK (*Wisconsin Sta. Rpt. 1905*, pp. 129-156, pls. 2).—This article contains a review of the literature of this subject and the results of experiments conducted in 1889, and again in 1899 and 1900.

The purpose of the experiments was to determine the amount of salt in addition to that obtained in feed and water necessary to maintain the health of cows and the normal flow of milk. In each of the 3 trials conducted the cows showed an abnormal appetite for salt after having been deprived of it for 2 or 3 weeks, but did not appear to be affected in health until a much longer period, varying in individual cases from less than 1 month to more than 1 year. In all cases cows deprived of salt finally reached a condition of low vitality from which recovery was rapid when salt was supplied.

The results, however, indicated that when cows are not giving milk they may be maintained in good health for an indefinite period with no salt other than that contained in normal rations. It is estimated that the daily ration fed contained the equivalent of 0.75 oz. of salt, which is assumed as the minimum amount required per 1,000 lbs. live weight for an animal not producing milk.

Cows giving milk should therefore receive in addition enough salt to compensate for the chlorin in the milk, which is estimated as equivalent to 0.6 oz. of salt for each 20 lbs. of milk. As a slight excess will do no harm it is recommended that cows be given at least 1 oz. of salt per day. It is considered evident, however, that the amount of additional salt required will vary greatly in different localities.

The length of time required in these experiments for demonstrating the injurious effects of depriving cows of salt raises the question in the mind of the author if the periods usually employed in feeding experiments have been sufficiently long to show the physiological effect of any particular food.

Influence of dehorning and tuberculin testing on the milk secretion of dairy cows, F. W. WOLL and G. C. HUMPHREY (*Wisconsin Sta. Rpt. 1905, pp. 118-124*).—Fourteen cows were subjected to the tuberculin test and then dehorned. The milk of these cows as regards yield and composition was compared with the milk of cows dehorned but not tuberculin tested, of cows tuberculin tested but not dehorned, and of cows neither dehorned nor tuberculin tested. The result showed on an average a decrease of about 8 per cent in the yield of milk for the first few days after dehorning, but a loss of only about 2 per cent in the yield of butter fat. Dehorning, therefore, increased the fat content of the milk 0.27 per cent. These results are noted as being in accord with the results of investigations at other experiment stations which are cited. The tuberculin test was apparently without effect upon milk secretion.

The university dairy herd, 1904-5, G. C. HUMPHREY and F. W. WOLL (*Wisconsin Sta. Rpt. 1905, pp. 69-107, pl. 1, figs. 12*).—Descriptions and illustrations are given of 12 cows added to the herd since the previous report (*E. S. R., 16, p. 813*), and records of 34 cows for the full year are reported and discussed.

The most profitable cow was a Jersey, which produced 6,790.9 lbs. of milk and 389.87 lbs. of butter fat at a net profit over cost of feed of \$61.22. The average production of the 34 cows was 6,439.5 lbs. of milk and 280.57 lbs. of butter fat. The average net profit per head was \$35.20. As compared with the previous year, the results show a decrease in average production and in net profit, attributed in part to poorer pasturage and an inferior quality of silage.

The average production of the 34 cows by breeds was as follows: Jersey (6 cows), 5,816.6 lbs. of milk and 315.8 lbs. of fat; Guernsey (9 cows), 5,193.5 lbs. of milk and 270.8 lbs. of fat; Holstein (7 cows), 8,372.5 lbs. of milk and 296.29 lbs. of fat; Shorthorn (6 cows), 6,116.2 lbs. of milk and 234.52 lbs. of fat; Red Polled (4 cows), 7,050.6 lbs. of milk and 290.97 lbs. of fat; and Brown Swiss (2 cows), 6,898.2 lbs. of milk and 281.14 lbs. of fat. The results as regards butter-fat production and net profit were, therefore, favorable to the Jerseys. The data, however, are considered insufficient to warrant general deductions concerning the value of the various breeds.

As in the previous reports, a comparison was made of the cows by types. Twelve cows of the extreme dairy type produced on an average 5,958.6 lbs. of milk and 286.06 lbs. of fat at a profit over cost of feed of \$37.92. Ten cows of the large dairy type produced 6,874.5 lbs. of milk and 297.34 lbs. of fat at a profit of \$36.39. Twelve cows of the dual purpose type produced 6,558 lbs. of milk and 261.11 lbs. of fat at a profit of \$31.49. The average net profit of the 3 types for the period from 1898 to 1905 was respectively \$39.08, \$39.31, and \$35.22. On the whole, the large dairy cows have been the most profitable. It is therefore believed that attention should be given to the matter of size in the selection of dairy animals.

Analyses are given of the feeding stuffs used. A comparison of the ration fed during the year with those of previous years showed a maximum yield and fat content of milk coincident with a narrowing of the ration. It is not believed that a narrower nutritive ratio than 1:6 will be found advantageous except in the case of high producers. It is suggested that the nutritive ratio may profitably range between 1:6 and 1:7, the dry matter from 20 to 24 lbs., and the digestible protein from 2 to 2.4 lbs.

Official tests of dairy cows, 1904-5, F. W. WOLL (*Wisconsin Sta. Rpt. 1905, pp. 125-127*).—This is a brief account of 864 tests reported in detail in Bulletin 131 of the station (E. S. R., 17, p. 963).

Market milk, J. B. LINDSEY and P. H. SMITH (*Massachusetts Sta. Bul. 110, pp. 48, figs. 5*).—Part 1 of this bulletin is a general discussion on the character, composition, and food value of milk.

Part 2 is a résumé of the conditions of milk production observed by the authors during the winter months in the region supplying Amherst and Northampton, Massachusetts. The majority of the stables were found to be dirty, poorly lighted, and badly ventilated. Many of the animals were exceedingly dirty. No herd had been subjected to the tuberculin test. The health of the animals appeared satisfactory in most cases. No fault was found with the water supply in the majority of cases nor to the food supply in any instance from the standpoint of the health of the animals. Modern appliances for the handling of milk were not in general use.

Part 3 gives the results of chemical and bacteriological investigations of 113 samples collected during the period from July to March from milkmen while engaged in retailing the milk. The acidity expressed in degrees or the number of cubic centimeters of tenth normal sodium hydroxid solution required to neutralize 100 cc. of milk varied from 12 to 21.3 and averaged 14.7 on the day of collection, thus indicating that the majority of the samples were not over 12 to 24 hours old when tested. The average composition of 110 samples was as follows: Total solids, 13.23 per cent; fat, 4.49 per cent, and solids-not-fat, 8.74 per cent. In general the samples were above the Massachusetts standard. Only 2 were known to have been watered and 5 were considered somewhat suspicious. All the milk retailed at 6 cts. per quart. Of 101 samples, 50 contained more than 50,000 bacteria per cubic centimeter; 41, more than 100,000; 13, more than 500,000, and 9, more than 1,000,000. The proportion of acid organisms in the majority of the samples varied between 10 and 35 per cent. The liquefying bacteria exceeded 10 per cent in 22 out of 69 samples. A disagreeable odor was detected in 65.5 per cent of the samples, which was considered as due particularly to the habit of allowing the milk to stand exposed to the air of the stable for some time after milking. It is considered clear that a great deal of the milk offered for general consumption was not produced under satisfactory sanitary conditions.

In part 4 the authors make practical suggestions concerning the duties of producers and consumers of milk. When milk testing 4.5 to 5 per cent of fat is produced under reasonably satisfactory sanitary conditions the authors believe that 8 cts. per quart must be obtained in order to secure a fair return from the investment.

Care of milk on the farm and the manufacture of butter and cheese, R. W. CLARK (*Utah Sta. Bul. 96, pp. 109-135, figs. 4*).—This is a popular discussion on the sanitary production and handling of milk and improved methods of butter and cheese making with the results of some experimental work.

The author, in conjunction with J. A. Crockett, made some experiments in canning cheese. After pressing in molds the cheese was placed in tin cans holding from 5 to 30 lbs., the cans having been previously paraffined on the inside to prevent rusting. This method prevented loss in weight and lessened the attention required during curing, but increased the cost of the cheese from 1 to 3 cts. per pound. After curing for 90 days canned, paraffined, and unparaffined cheese scored practically the same. The loss in weight of the paraffined and unparaffined cheese was 5.5 and 8.6 per cent, respectively.

In 8 trials paraffined cheese lost 3.7 per cent in weight and unparaffined cheese 7.6 per cent during curing for 3 months at 65° F. The scores averaged

91.45 and 93.95, respectively, for the 2 lots. In further experiments cold storage gave better results than the ordinary curing room for both paraffined and unparaffined cheese. It was estimated that paraffining cheese effected a saving of 22.5 cts. per hundred when cheese was cured from 90 to 100 days at ordinary temperature.

The Babcock test was compared with chemical analysis of 15 samples of skimmed milk, the test being made with about one-fourth more acid than usual and the tester run at a higher speed and several minutes longer than customary. The average results for the 2 methods were, respectively, 0.1 and 0.198. In tests with 4 makes of hand separators, different temperatures of milk and variations in speed of separator bowl were compared. With cold milk and low speed, 0.44 per cent of fat was left in the skim milk as determined by the Babcock test.

"The most satisfactory skimming was secured when the milk had a temperature of about 85° F. and the separator operated according to the directions of the manufacturers."

On the detection of a tainted condition in pasteurized milk, H. L. RUSSELL and C. HOFFMANN (*Wisconsin Sta. Rpt. 1905, pp. 222-226*).—The station was called upon to investigate the cause of an undesirable flavor in the product of a large dairy company which was pasteurizing its milk for the general city trade. The investigation showed that the trouble was due to the custom of passing steam through the pasteurizing machine immediately before the milk was turned into the apparatus. Some of the steam condensed in the machine and this not infrequently contained enough grease or oil to impart an objectionable flavor to the milk. The case is considered interesting as indicating how much trouble can sometimes be caused by an apparently trivial circumstance.

Studies on pasteurization of milk in a "continuous-flow" machine (Miller apparatus), H. L. RUSSELL and C. HOFFMANN (*Wisconsin Sta. Rpt. 1905, pp. 232-241, fig. 1*).—In determining the period of exposure, use was made of the following method, which is believed to have superior advantages over the colorimetric method ordinarily employed:

"The heater is first filled with water. To determine then the minimum period of time necessary for any particle of milk to pass through the machine, the exact time of starting the milk flow is noted, and also the appearance of the first indications of turbidity. This gives the time necessary for the most rapidly flowing particles of milk to pass through the machine. To find the maximum period of exposure, some samples of the milk are taken at the outlet at stated intervals, every 5 or 10 seconds or so, for a period of several minutes. A determination of the fat in these samples is then made.

"When the fat content has been restored to its original amount, it indicates that all of the water in the machine has been replaced by the flowing milk. By charting these fat determinations, not only can the minimum and maximum periods of exposure be ascertained with exactness, but the actual exposure for any proportion of the entire flow can also be found."

With the machine under investigation the results of tests showed that some of the milk passed through in 15 seconds and some in 45 seconds, but that most of the milk remained in the machine about 30 seconds. When the rate of flow was diminished about one-half, the minimum period of exposure was from 25 to 28 seconds and the maximum from 70 to 100 seconds.

Bacteriological examinations were made of the raw milk and the milk after heating, after cooling with water, and after cooling with ice water. The rate of flow approximated 1,800 lbs. per hour and the rate of exposure ranged from 15 to 50 seconds. From the results of tests made under both winter and summer conditions it is considered apparent that the number of bacteria capable

of resisting the heating process is subject to wide fluctuations. This is considered due to the wide variation in time to which the milk was exposed. When the temperature fell below 150° F., the bacterial content was very greatly increased. On the whole, the results showed a much higher bacterial content than that found in milk treated with the intermittent method. It is believed that if a temperature of not less than 160° F. is maintained the bacterial content of the milk will be fairly satisfactory, although not so low as when a longer application is made at a low temperature.

Bacteriological test of a bottle-washing device, H. L. RUSSELL and C. HOFFMANN (*Wisconsin Sta. Rpt. 1905, pp. 227-231, fig. 1*).—The efficiency of a combined bottle-washing and sterilizing machine was investigated. The apparatus in question was capable of washing from 2,400 to 4,000 bottles per hour. The cleaning was considered surprisingly well done and sterilization was considered a valuable adjunct to the washing. When exposed to steam for 14 seconds the bacterial content of the bottles was found to be 268,140 bacteria per bottle and when exposed for 30 seconds, 13,740. Even when exposed for 30 seconds the bottles were by no means rendered sterile.

Bottles handled in an ordinary commercial way and exposed to steam for 10 minutes were found to contain a much smaller number of bacteria. In the condensation water in bottles which had been steamed and allowed to stand at room temperatures for 24 hours the number of bacteria varied from 1,786,800 to 3,981,000. In 2 corresponding series of bottles containing no condensation water the numbers of bacteria were 60,710 and 330,100. In a series of steamed bottles exposed to the air for 24 hours the number of bacteria averaged 292,450 per bottle, while in a similar series which had been covered with a linen cloth the number of bacteria averaged 11,615, showing the importance of keeping bottles covered.

The milk of sheep in Corsica, COMTE (*Jour. Pharm. et Chim., 6. ser., 24 (1906), No. 5, pp. 199-204*).—Analyses were made of the milk of 14 flocks of sheep aggregating 1,917 individuals. The results are interpreted as showing a superior quality of the milk for cheese making as compared with that of sheep in the region of Roquefort.

Gathered-cream plants, J. MICHELS (*South Carolina Sta. Bul. 118, pp. 12, dgm. 1*).—The author believes that dairy farming should be encouraged in South Carolina, and in this bulletin comments on the value of cream plants to farmers making dairying a secondary matter, outlines a method of organizing a cooperative creamery, and gives general plans for the construction and operation of the plant with an itemized statement of the equipment necessary.

The relation of lactic-acid bacteria to the formation of butter flavor in milk serum, J. MICHELS (*Wisconsin Sta. Rpt. 1905, pp. 198-206, fig. 1*).—In the experiments reported butter made in the ordinary way was compared with butter made by the Le Clair method, in which a large quantity of ripened skim milk is added to sweet cream and the mixture churned immediately. Data were obtained as regards the flavor of the 2 kinds of butter, the bacterial content, and the keeping quality. The author's conclusions are as follows:

“From the foregoing data it is apparent that the development of the desirable flavors in butter may be made independent of the butter fat in the cream, that the growth of the lactic-acid bacteria in the milk serum results in the formation of by-products which are readily absorbed by the butter fat when brought in contact with the same and give the characteristic flavor to the butter. This would seem to indicate that the fat itself does not enter into the process, except in a passive way. It does not seem to make any particular difference, so far as the degree or intensity of the flavor is concerned, whether it develops in

direct contact with the fat, or whether it is formed independently of it and is later absorbed.

"The germ content of butter made from cream to which a ripened skim-milk starter has been added was generally considerably less than that of butter made in the usual way. This marked variation in germ content does not apparently harmonize with the uniformity of flavor noted in the 2 processes, but this seeming discrepancy is capable of ready explanation. Where the ripening changes occur in the skim milk itself, germ growth goes on to such a point that a great many of the bacteria die, leaving their characteristic by-products in the milk serum. Where the ripening occurs in contact with the cream, excessive acidity is not produced, and therefore a larger germ content is actually found, although perhaps the degree of flavor is not any more marked."

The influence of changes of temperature on the results obtained with a lactometer in calculating milk solids, P. C. RANNEY (*Wisconsin Sta. Rpt. 1905, pp. 190-197*).—In correcting lactometer readings for temperature it is quite customary to add 0.1 for each degree above 60° F. and subtract 0.1 for each degree below 60°.

The experimental work reported indicates that this method is reasonably accurate when limited to temperatures between 50 and 70°. For correcting readings taken at temperatures above 70° the addition of 0.2 for each degree was found to give closer results than the addition of 0.1.

In calculating total solids by the Babcock formula it is believed that corrections for temperature should be made by Fleischmann's or Vieth's tables, which, however, are not considered as giving accurate results for readings taken at temperatures above 80°. In order to eliminate all errors, the author concludes from the results of his experiments that lactometer readings should be taken at 60°.

Estimating the amount of water in butter by the overrun obtained in each churning, O. UERLING and A. WALLIN (*Wisconsin Sta. Rpt. 1905, pp. 186-189*).—In the experiments the results of which are given in this article the water content of butter was determined in most instances by chemical analysis, but was estimated in some trials by the amount of overrun.

The authors conclude that the water content of butter is increased by working immediately after washing as compared with working after the butter has drained for about half an hour, and that the water content is also increased by allowing the granular butter to remain in water for some time before working. The water content of the butter was not always increased by increasing the amount of churning in the wash water nor by washing in warm water.

Renovated butter: Its origin and history, L. WELLS (*U. S. Dept. Agr. Yearbook 1905, pp. 393-398*).—This is a brief account of renovated butter. At the present time there are 78 factories manufacturing this product. During the fiscal year 1905 the output of these factories amounted to 60,000,000 lbs.

Paraffining cheese, L. F. ROSENGREN (*Nord. Mejeri Tidn., 21 (1906), Nos. 26, pp. 352, 353; 27, pp. 365, 366, figs. 3*).—Experiments with paraffining different kinds of full-cream and half-skim Swedish cheese showed losses in weight during 3 to 7 months' storage of 4.7 to 11.2 per cent.—F. W. WOLL.

The Swiss cheese industry of Wisconsin; whey butter making, E. H. FARRINGTON (*Wisconsin Sta. Rpt. 1905, pp. 157-180, figs. 12*).—This is a briefer account of observations published in Bulletin 132 of the station (E. S. R., 17, p. 1186).

Lactose-fermenting yeasts, the cause of an abnormal fermentation in Swiss cheese, E. G. HASTINGS (*Wisconsin Sta. Rpt. 1905, pp. 207-221, figs. 6*).—This is a more technical account of investigations previously reported in bulletin form (E. S. R., 17, p. 498).

Compilation of analyses of fodder articles and dairy products, made at Amherst, Mass., 1868-1905, E. B. HOLLAND and P. H. SMITH (*Massachusetts Sta. Rpt. 1905, pp. 200-223*).—These tables show the composition, digestibility, and fertilizer ingredients of various products.

VETERINARY MEDICINE.

Characteristics of some of the contagious and infectious stock diseases, A. W. BITTING and G. H. ROBERTS (*Indiana Sta. Bul. 113, pp. 269-288, figs. 20*).—The purpose of the present bulletin is to present an outline of the chief symptoms and post-mortem lesions observed in the common diseases of live stock. The most approved lines of treatment in the case of each disease are given, and mention is also made of State and Federal laws relating to these diseases.

How parasites are transmitted, B. H. RANSOM (*U. S. Dept. Agr. Yearbook 1905, pp. 139-166, figs. 50*).—The parasites referred to in this article are grouped into arthropods, roundworms, tapeworms, flukes, and protozoa. Examples are given of these various classes of parasites, with notes on their life history and the means by which they are transmitted from one animal to another.

The transmission of tuberculosis from man to cattle, A. EBER (*Berlin, Tierärztl. Wchnschr., 1906, No. 28, pp. 527-537*).—A critical review is given of the literature relating to this highly controversial problem. The author examined carefully the evidence presented by Koch for his belief in the nonidentity of human and bovine tuberculosis. The experiments carried out by the German Imperial Health Office are believed not to support the contentions of Koch.

Human tuberculosis cultivated in vivo in domestic animals, G. MOUSSU (*Compt. Rend. Soc. Biol. [Paris], 61 (1906), No. 26, pp. 95-97*).—When cultures of human tubercle bacilli were suspended in the intestinal cavity of cattle and other animals it was found that these animals would soon give a reaction to tuberculin, which existed for a year or more, although no true infection took place.

Milk and dairy products as sources of infection in tuberculosis, O. MÜLLER (*Jour. Compar. Path. and Ther., 19 (1906), No. 1, pp. 19-33*).—As a result of a study of the literature of this subject, together with personal observations and experiments, the author believes that the infectiousness of milk is chiefly referable to tuberculosis of the udder and that cows in which the udder is not affected do not excrete tubercle bacilli or at least only to a very slight extent. The transmission of tuberculosis, therefore, takes place through the milk of cows affected with the mammary form of the disease. In cases, however, in which the disease has reached an advanced stage without affecting the udder, tubercle bacilli may be found in the milk. The disease prevails especially in dairy regions among calves and pigs, and in order to avoid danger from its further dissemination it is necessary to observe great cleanliness about the dairy and sterilize all milk of tuberculous cows before feeding to calves or pigs.

The milk of tuberculous cows, G. MOUSSU (*Arch. Wiss. u. Prakt. Tierheilk., 32 (1906), No. 3, pp. 279-294, pls. 2*).—In this article particular attention was given to the study of the origin of tuberculous mammitis. The literature relating to this subject is briefly reviewed and notes are given on the pathological changes produced in the udder after tuberculous infection.

As a result of the author's investigations it is concluded that the milk of all tuberculous cows should be excluded from utilization without previous treatment. This is considered necessary on account of the fact that mammary tuberculosis can not be recognized or diagnosed in its early stages. Apparently the disease assumes such similar forms and such a similar course in both man

and cattle that the results obtained in the study of one species may be applied to the other.

Tuberculosis among dairy cows, W. L. LITTLE (*Jour. Compar. Path. and Ther.*, 19 (1906), No. 1, pp. 48-50).—Circumstances are related with regard to the unusual prevalence of tuberculosis in a herd of 30 cows the owner of which appeared to take great pains in caring for and feeding animals and in keeping the stables and cows in a cleanly condition. The cows were fed a generous and suitable ration, the stables were well built, with good drainage and concrete floors, and sand bedding was used and changed daily. Good ventilation was also provided. Nevertheless the disease prevailed to such an extent that the owner felt compelled to go out of the business. The prevalence of the disease is supposed to have been due to the fact that the cows were kept confined for about 6 months of the year and that the calves were allowed to suck the cows without regard to whether they were tuberculous or not.

The spread of tuberculosis by means of male animals from the standpoint of the breeder, RICHTER (*Berlin. Tierärztl. Wechschr.*, 1906, No. 10, pp. 169-173).—It is frequently asserted that tuberculosis may be transmitted by male animals to offspring directly, through the agency of the mother animal or by means of a susceptibility to tuberculosis. The literature relating to this subject is critically reviewed.

The author concludes that male animals are not capable of transmitting tuberculosis to offspring except possibly in an indirect manner by first infecting the mother animal. The hereditary transmission of the tendency to tuberculosis is considered as of very rare occurrence.

Pleural and peritoneal tuberculosis in cattle, J. F. HEYMANS (*Arch. Internat. Pharmacol. et Théor.*, 14 (1905), No. 5-6, pp. 375-387, pl. 1).—One of the most important features in the study of tuberculosis is the determination of the character and growth of tubercles found in cases of this disease. The author gave particular attention to the tubercles found on the pleura and peritoneum of cattle. These tubercles were studied not only to determine their microscopic character but also their virulence.

It appears from this study that a considerable portion of the pathological alterations on the serous membranes in the cases of bovine tuberculosis are not tubercles, or agglomerations of more or less detached tubercles, but simply inflammatory conditions which are at first progressive and later regressive. These inflammatory areas are due to irritating substances which come from neighboring tubercles. The virulence of the true tubercles is also found to vary greatly. In many cases it was impossible to obtain any virulent tubercle bacilli from them.

Failures in the tuberculin test on cattle, A. CARINI (*Arch. Wiss. u. Prakt. Tierheilk.*, 32 (1906), No. 6, pp. 562-573).—The special purpose of this article is to present a summary of the author's investigations regarding the reliability of the tuberculin test. As a result of numerous experiments the author comes to the conclusion that the percentage of failure in tuberculin tests is estimated too low by most writers on this subject. According to the author's experience failure may be expected in about 17 per cent of cases, even where the greatest care and precaution are exercised.

Vaccination against tuberculosis of young ruminants in the alimentary tract, A. ARLOING (*Compt. Rend. Acad. Sci. [Paris]*, 142 (1906), No. 26, pp. 1487-1489).—As a result of investigation along this line the author comes to the conclusion that an active immunity toward tuberculosis may be produced in young ruminants by feeding them cultures of either human or bovine tubercle bacilli after these organisms have been properly attenuated. There appears to

be little choice in this regard between the human and bovine bacilli. A reaction to tuberculin takes place before any infection has occurred, therefore, in the absence of all tuberculous lesions.

The effects of tuberculin absorbed by the digestive tract in healthy and tuberculous animals, A. CALMETTE and M. BRETON (*Compt. Rend. Acad. Sci. [Paris]*, 142 (1906), No. 11, pp. 616-618).—The author's experiments were carried out on guinea pigs, for the reason that these animals are particularly susceptible to tuberculosis.

It was found that tuberculin absorbed by the alimentary tract has a toxic effect upon nontuberculous animals and that this toxicity is particularly manifest in young animals. There appears to be no tendency toward the establishment of a tolerance for the ingestion of the gradually increasing doses of tuberculin. If guinea pigs are rendered tuberculous by a single alimentary infection they react regularly to tuberculin if they are fed this reagent in doses of 1 mg. which are entirely without effect upon healthy guinea pigs. It was also shown by the experiments in question that in the case of tuberculous animals a reaction takes place to tuberculin whether this reagent is administered hypodermically or by way of the alimentary tract.

Griserin as a treatment of tuberculosis, SPRINGEFELDT (*Arch. Wiss. u. Prakt. Tierheilk.*, 32 (1906), No. 6, pp. 545-561).—Griserin has been proposed by certain German investigators as a chemical cure for tuberculosis in human beings and animals.

The author tested this chemical on 24 guinea pigs, which were artificially inoculated with tuberculosis and afterwards treated with griserin. In no case was the disease checked by the treatment with griserin. The lesions spread and the disease showed a tendency to become generalized as rapidly as where no treatment was applied.

The action of essence of turpentine upon the virus of glanders, tuberculosis, and anthrax, V. GALTIER (*Jour. Méd. Vét. et Zootech.*, 57 (1906), Mar., pp. 140-147).—It has long been known that the virus of glanders is quite easily affected by the essence of turpentine. The tubercle and anthrax bacilli, however, are far less susceptible. According to some experiments the tubercle bacillus is not destroyed by immersion for 8 hours in essence of turpentine. It would appear, therefore, that this substance is not suitable for disinfecting objects which have become contaminated with the tubercle bacillus.

Turpentine is also of little avail in destroying anthrax infection, particularly if spores are present. Experiments were carried on by the author in inoculating guinea pigs and rabbits with anthrax virus followed by vaccination with 0.25 cc. of essence of turpentine. The turpentine appeared in all cases to prolong life somewhat, and in a few instances the animals recovered entirely from a fatal dose.

The effect of preparations from tubercle bacilli upon the tuberculous organism, A. WASSERMANN and C. BROOK (*Deut. Med. Wchenschr.*, 32 (1906), No. 12, pp. 450-454).—In the experiments reported in this article the authors gave attention chiefly to establishing the location of antituberculin and tuberculin in the organism of the affected animal and the reaction between these two substances.

It appears that antituberculin may be quite readily demonstrated in the tuberculous organs of man, guinea pigs, cattle, and other animals. During the treatment of tuberculous animals from preparations of tubercle bacilli a specific antituberculin appears in the general blood circulation. While the antituberculin is present in tuberculous organs of tuberculous animals it does not appear in the serum. If such animals are treated with tuberculin or other preparations from tubercle bacilli these materials, on account of their affinity

for antituberculin, pass into the tuberculous organ and become combined with the antituberculin. The specific reaction of tuberculous tissue, therefore, takes place on account of the fact that the tuberculin is attracted by the antituberculin into the tuberculous tissue and becomes localized in such structures.

The virulence of tubercle bacilli, A. MARMOREK (*Berlin. Klin. Wchnschr.*, 43 (1906), No. 11, pp. 328, 329).—One of the difficulties always incurred in work with tubercle bacilli is found in determining their virulence. The author attempted to work out an original method of securing evidence of slight variation in the virulence of different cultures of tubercle bacilli. For this purpose white mice were selected and on account of their high resistance to the tubercle bacillus were previously treated with injections of quinin chlorate. This drug has the effect of paralyzing the white blood corpuscles so that the organism was less resistant to infection. During these experiments it was found that the virulence of tubercle bacilli depends primarily upon the age of the culture and grows less as the culture becomes older.

The resistance of tubercle bacilli to acid, C. CIACCIO (*Compt. Rend. Soc. Biol. [Paris]*, 60 (1906), No. 12, pp. 585, 586).—It is frequently stated that the acid resistance of the tubercle bacillus is due to the presence of a fatty acid in the body of the bacillus. According to the author's investigations, however, while the tubercle bacillus does contain fatty substances the specific coloration of the bacillus and its acid resistance is not due to fatty acids, but to some other substance.

The homogenization of acid-resistant bacilli, L. KARWACKI (*Ztschr. Tuberkulose*, 9 (1906), No. 3, pp. 226-228).—In homogenizing tubercle bacilli of various sources, the best results are obtained when potatoes and diluted serum are used in the place of glycerinated bouillon. Homogeneous cultures of tubercle bacilli when transferred from one serum medium to another have a tendency to develop flocculent deposits. The bovine tubercle bacillus appears to be quite difficult to homogenize and this may be taken as a rather constant characteristic of the bacillus.

Anthrax, B. V. FURSENKO (*Arch. Vet. Nauk [St. Petersburg]*, 36 (1906), No. 6, pp. 393-402, fig. 1).—A study was made of the behavior of anthrax in pure cultures and of the progress of the disease after the inoculation of rabbits, particular attention being given to the localization of the bacilli in affected animals.

Actinomycosis or lumpy jaw, D. E. SALMON and T. SMITH (*U. S. Dept. Agr., Bur. Anim. Indus. Circ.* 96, pp. 10).—This is a reprint, with a slight revision, from the Special Report on the Diseases of Cattle (E. S. R., 16, p. 708).

False foot-and-mouth disease, M. MÜLLER (*Deut. Tierärztl. Wchnschr.*, 14 (1906), No. 28, pp. 334, 335).—The author observed several cases of mouth disease in cattle. The symptoms to be seen in the mucous membrane of the mouth resembled somewhat those of true foot-and-mouth disease, but were found to be due to the spines of *Oronis spinosa* which occurred in considerable quantity in the hay fed to the cattle.

Calf scours: A new method of treatment, L. A. KLEIN (*South Carolina Sta. Bul.* 122, pp. 9).—On account of the general importance and prevalence of scours among calves fed on skim milk, the author tested the value of formalin added to the milk before feeding to the calves.

In these experiments 12 calves were treated by adding formalin to the milk at the rate of 1 part to 4,000. Eleven calves recovered without any further treatment—7 on the second day, 3 on the third, and 1 on the ninth. In one case it was found necessary to administer castor oil, creolin, and subnitrate of bismuth before a complete recovery was brought about. In 3 cases of scours in calves running at pasture and receiving grain at the same time the formalin treatment did not prove effective.

Foot-rot of sheep, J. R. MOHLER and H. J. WASHBURN (*U. S. Dept. Agr., Bur. Anim. Indus. Circ. 94*, pp. 117-137, fig. 1).—This circular is reprinted from the annual report of the Bureau for 1904 (E. S. R., 17, p. 715).

The parasite of common sheep scab, C. M. JOHNSTON (*Orange River Colony Dept. Agr., Biol. Div. Leaflet 2*, pp. 6, figs. 4).—Distinction is made between common scab, head scab, and foot scab as affecting sheep. The common scab mite is described and notes are given on its life history.

According to the present law in the Orange River Colony the second dipping of sheep is required to be given 14 to 18 days after the first. It is proposed to change this so as to require that it be done within 10 to 14 days.

A clinical study of braxy, R. FROEHLNER (*Dent. Tierärztl. Wchuschr.*, 14 (1906), No. 30, pp. 359, 360).—Occasion was offered for a study of a number of cases of this disease in sheep. The feed which the sheep received was examined and found to be in good condition. It was therefore not concerned in the production of the disease.

According to the evidence obtained it appears that the sheep became infected during the process of shearing as the result of using uncleanly shears. A bacteriological examination showed the presence of the bacillus of malignant oedema.

Bursattee, F. E. PLACE (*Vet. Rec.*, 18 (1906), No. 923, p. 646).—It has been found that iodized phenol is an excellent remedy for this disease. Experiments indicate that iodine is the most certain agent for destroying nematode worms in the blood and feces of infected animals.

Copper salts as a supposed preventive of hog cholera, S. AVERY (*Nebraska Sta. Rpt. 1905*, pp. 116, 117).—Hogs were fed a solution of copper sulphate at the rate of 1 lb. per gallon of water, with or without Rochelle salts, to render the solution alkaline. Since the hogs seemed to endure the solution without Rochelle salts, as well as when this chemical was added, the plain copper sulphate solution was used at the rate of 1 oz. per day for each hog. This treatment continued for several weeks and caused no trouble except an occasional loss of appetite. A test was then made to determine whether the solution of copper sulphate was of any value in preventing infection of hog cholera. It was found in this experiment that hogs treated with copper sulphate became affected and died in the same manner as those which were not treated.

Hog cholera, F. KOSKE (*Arb. K. Gsundtsamt.*, 24 (1906), No. 2, pp. 305-345).—As a result of numerous cultures and observations on *Bacillus suispestifer*, the author determined that the hog cholera bacillus may retain its virulence perfectly for 2 or 3 months in ordinary agar cultures or for 120 to 160 days in the buried carcasses of pigs.

The cultures were destroyed by subjection to a 2½ per cent cresol solution for 1½ minutes or a 5 per cent carbolic solution for 3 minutes. Numerous experiments were made in testing the susceptibility of various laboratory animals and larger domestic animals to the organism of hog cholera, and notes are given on the pathological condition produced by such inoculation. In the author's experience there is little difference in the agglutination results as obtained by the use of a monovalent and polyvalent serum. Serum obtained from an inoculated ass was able to protect hogs against fatal doses of hog cholera bacilli previously inoculated intravenously.

The etiology of hog cholera and swine plague, F. HUTYRA (*Berlin. Tierärztl. Wchuschr.*, 1906, No. 32, pp. 607-610, figs. 5).—The literature relating to the controverted points regarding hog cholera and swine plague is briefly reviewed.

In experiments carried out by the author it was found that a filtered blood serum or fluid from the innings of hogs affected with acute swine plague was capable of producing an acute infectious disease after subcutaneous inoculation

in young pigs. In some cases such inoculation produced a rapidly fatal hemorrhagic septicemia. The author believes that there is some evidence in favor of assuming the existence of an ultramicroscopic organism as the cause of swine plague.

Hog cholera and swine plague in South Africa, A. THEILER (*Fortschr. Vet. Hyg.*, 4 (1906), No. 6, pp. 121-128).—As the result of a long-continued study of these diseases in South Africa, the author concludes that *Bacillus suisceplicus* as it occurs in South Africa is practically identical with the usual form observed in Europe. The pathological lesions produced in South Africa are also the same as those described by European investigators.

The author produced an infection in 4 out of 7 hogs which were fed large quantities of the bacteria, and suggests that the large percentage of infection may have been due to the presence of intestinal worms. In nearly all cases hog cholera is associated with swine plague in South Africa. In fact, the author never observed but one case of swine plague in which *B. suisceplicus* was demonstrated and in which hog cholera was not present. Apparently there is no epizootic in South Africa due to *B. suisceplicus*, but the common infectious hog disease is associated with hog cholera, which gives *B. suisceplicus* an opportunity to infect hogs.

Is the virus of swine plague and hog cholera filterable? R. OSTERTAG (*Berlin. Tierärztl. Wchenschr.*, 1906, No. 34, pp. 623-626).—In experiments in the filtration of the virus of swine plague the results were negative in some cases and positive in others. Where positive results in infection took place it appeared that the infection was due to some other agent than the organism of swine plague.

The author also carried on some experiments in filtering the virus of hog cholera to determine whether this virus was infectious as shown to be in some cases by the Bureau of Animal Industry of this Department. In the first test the filtered virus was not infectious, but when material from this country was used in the experiments it was found to be virulent after filtration. The author expects within the near future to develop a practical system by means of which hog cholera may be controlled.

The relation of *Bacillus pyogenes suis* to swine plague, F. KOSKE (*Arch. K. Gsndtsamt.*, 24 (1906), No. 2, pp. 181-195).—Numerous investigators have attempted to determine the exact relationship of *B. pyogenes suis* to swine plague. The literature relating to this subject was briefly reviewed by the author. The organism in question was cultivated on a number of nutrient media and notes are given on the behavior of the bacillus. The organism is killed by subjection to a temperature of 55° C. for 20 minutes or by treatment with a 1 per cent corrosive sublimate solution for 1 minute, a 3 per cent cresol solution for 1 minute, or a 5 per cent carbolic acid solution for 1½ minutes.

Inoculation experiments were made on laboratory animals and pigs, the bacterial cultures being injected into the blood, lungs, body cavity, and musculature, or being given in feeding experiments and by inhalation. Any of these methods of inoculation may cause the death of some of the experimental animals under symptoms of acute septicemia, but in most cases there is only a local abscess formation. In no case was there a development of the usual symptoms of swine plague in the lungs. Accordingly the author concludes that *B. pyogenes suis* may cause general septicemia or pyemia or local abscesses, but is not the true cause of swine plague.

Toxic phenomena observed as a result of injecting dead glanders bacilli into the stomach, J. CANTACUZÈNE and P. RIEGLER (*Compt. Rend. Soc. Biol.* [Paris], 61 (1906), No. 27, pp. 231-233).—The experiments reported in this paper were carried out on guinea pigs, both young and adult. It was found that

when large quantities of dead glanders bacilli were injected into the stomach of guinea pigs they produced more or less severe intoxication followed by a rapid death in cases where large numbers of the bacilli were used. Not only the soluble products of the bacilli but the bacterial bodies themselves pass through the intestinal wall and are found in the ganglia, spleen, and lungs, where they may produce broncho-pneumonia. Where small quantities of the dead bacilli are used a tolerance is developed on the part of the animal, which may last for a period of 3 months.

A disease of the horse simulating farcy, F. S. H. BALDREY and G. D. MARTIN (*Jour. Trop. Vet. Sci.*, 1 (1906), No. 3, pp. 316-319).—In a case which closely resembled farcy an organism was obtained which is somewhat shorter and thicker than that of the glanders bacillus. Inoculation of guinea pigs with this organism produced a mild illness which lasted for 4 or 5 days, but the lesions were not fatal. The period of incubation was 4 days.

An anthrax-like bacillus found in a horse suspected of anthrax, R. E. MONTGOMERY (*Jour. Trop. Vet. Sci.*, 1 (1906), No. 3, pp. 284-294).—In a suspected case of anthrax it was found impossible to obtain cultures of the true anthrax bacillus. The symptoms and lesions were apparently those of anthrax. Notes are given on the behavior of the organism on various cultural media. From inoculation experiments it was found possible to obtain pure cultures of the organism which did not produce serious disease in most cases. The exact relationship of the organism is not known.

Experimental nagana, A. RODET and G. VALLET (*Compt. Rend. Acad. Sci. [Paris]*, 143 (1906), No. 6, pp. 327, 328).—In previous experiments the authors have tested the effect of injections of the spleen of dogs into rats artificially inoculated with nagana.

Attention is called to the fact that a sudden reduction in the number of blood parasites may take place under other conditions in which the action of the spleen is excluded. It is necessary, therefore, to be rather cautious in drawing conclusions as to the effect of inoculations of spleen. The authors are disposed to ascribe the sudden disappearance of the blood parasites in the dog to a crisis in the disease during which the trypanosomes are destroyed by the action of a specific property of the blood.

Trypanosoma brucei and experimental nagana, A. RODET and G. VALLET (*Compt. Rend. Soc. Biol. [Paris]*, 61 (1906), No. 27, pp. 186-189).—As the result of an extended study of the blood parasites of nagana in rats and dogs, the authors conclude that some of the abnormal forms occasionally called ameboid are not regular stages in the development of the parasite, but are the result of abnormal stimulation of these organisms.

The parasites multiply rapidly in the blood, in especially large numbers in the capillaries of the liver. The blood parasites are also rapidly destroyed in the infected animal, and in this destruction certain organs are especially active, the spleen being most so and the liver least. The trypanosomes, however, may degenerate and die in the circulating blood. In most cases where secondary bacterial infection took place in the experimental animals the number of trypanosomes at the time of death was very small.

Souma, L. CAZALBOU (*Rev. Gén. Méd. Vét.*, 8 (1906), No. 89-90, pp. 240-248).—In the French Soudan a trypanosomiasis prevails among horses and cattle and is commonly referred to under the name souma. It has affected a large number of animals during the past 3 years, attacking 14 per cent of horses and cattle in certain localities. There appears to be some difference in the susceptibility of different breeds of cattle. Zebus are even more susceptible than common cattle. Notes are given on the symptoms and etiology of the disease. It appears to be carried by certain species of Tabanus.

Trypanosomiasis of Barbary in 1905, EDMOND and ÉTIENNE SERGENT (*Ann. Inst. Pasteur*, 20 (1906), No. 8, pp. 665-681).—A brief review is presented showing the distribution of various forms of trypanosomiasis in different parts of Barbary. It appears that about 9 per cent of dromedaries are infected and 0.17 per cent of horses.

Experiments in testing the virus of different forms of trypanosomiasis on rats and other experimental animals showed that the trypanosomes of the disease known as debab are not ordinarily carried by horse flies and are not capable of penetrating through healthy mucous membranes, as is the case with the trypanosome of dourine. The authors believe, therefore, in the existence of two distinct forms of trypanosomiasis in Barbary.

Congestive and hemorrhagic forms of pasteurellosis in the horse, FAIRISE (*Rev. Gén. Méd. Vét.*, 8 (1906), No. 89-90, pp. 225-240).—In the early stages of pasteurellosis in horses an acute congestive condition is frequently observed, but such congestion is ordinarily secondary to pulmonary lesions. In cases where serious hemorrhagic conditions prevail it is necessary to administer hemostatic drugs and also to reduce the temperature. Most of the drugs which might be thought of in this connection have certain disadvantages for the reason that they produce depression. Among these mention is made of acetanilid and quinin. The best results were obtained from the use of chlorid of lime and gelatin.

Experiments with Lorenz' organism of pneumonia, SCHWEIKERT (*Berlin. Tierärztl. Wchenschr.*, 1906, No. 30, pp. 567, 568).—A small piece of skin was removed from a horse affected with pneumonia, and from this material the organism of the disease was obtained in pure cultures. When used in inoculating a colt it produced the regular symptoms of the disease on the following day. Another colt exposed to natural infection also showed the usual symptoms, but recovered.

The etiology of pleuro-pulmonitis of horses, L. BARUCHELLO and A. PRICOLO (*Clin. Vet. [Milan]*, 29 (1906), No. 29, pp. 697-700).—The authors were unable to isolate any bacterial organism which could be considered as the cause of this disease. In the blood and spleen, however, certain corpuscles were observed which appeared to be of a protozoan nature and which may be concerned.

Feeding wild plants to sheep, S. B. NELSON (*Washington Sta. Bul.* 73, pp. 64, figs. 40).—Botanical descriptions and illustrations are given on 40 plants which occur on sheep ranges, which were considered worthy of investigation to determine their harmful and harmless character. Notes are given on losses which have occurred on sheep from time to time and which have generally been attributed to the action of poisonous plants. The flora of one region noted for the occurrence of poisoning contained 55 different plants, the most of which were gathered in a fresh condition and fed to sheep.

As a result of these experiments it appeared that *Zygadenus venenosus* may cause poisoning, but that *Delphinium menziesii* is not poisonous in any stage of growth. Among the lupines studied only *Lupinus ornatus* appeared to be poisonous. Neither arnica, wild cherry, nor any of the other plants studied caused symptoms of poisoning.

Poisoning of horses by the common horsetail weed (*Equisetum arvense*), A. T. PETERS and L. B. STURDEVANT (*Nebraska Sta. Rpt.* 1905, pp. 111-115, pl. 1).—On account of complaints of the poisoning of horses from eating common horsetail an examination was made of this plant and feeding experiments were carried out. In one case a mare was fed 40 lbs. of horsetail hay during a period of 3 weeks without showing any characteristic symptoms of poisoning. In all of the experiments the horses showed a distinct aversion to the weed.

The amount fed ranged from $\frac{1}{2}$ lb. per day, at the start, to 6 lbs. The first symptoms of poisoning in one case began on the fourteenth day and consisted of a crouching gait, partial loss of muscular control, pale bluish color of the mucuous membranes, and occasionally a subnormal temperature. The symptoms of staggering were most apparent on cold, rainy days. Decoctions of horsetail were also made and given to horses.

The authors conclude from their experiment that horsetail is not present in the hay of Nebraska in sufficient quantities to be dangerous to horses, but that in large amounts this weed might prove fatal.

Occurrence of barium in the Ohio Valley brines and its relation to stock poisoning, C. D. HOWARD (*West Virginia Sta. Bul. 103, pp. 281-295*).—From time to time reports have been given of farm animals dying under symptoms of poisoning without the cause being definitely determined, but the suspicion pointing to the salt used in each case.

An analysis of samples of brine obtained from the Ohio Valley of West Virginia showed the presence of barium chlorid in quantities ranging from 21 to 46 grains per gallon of brine. The barium chlorid is a highly poisonous drug causing a great increase of blood pressure and other effects similar to those of digitalis. The symptoms of poisoning resemble those of nitrate of potash, but the barium chlorid is much more poisonous. If the brine is treated with sodium sulphate or soda ash the barium, lime, and magnesium contained in the brine will be removed and the salt obtained from it will be of better quality for general use.

Brief notes are given on the character of the salt obtained in West Virginia and on the antiseptic properties of chlorid of lime and barium.

RURAL ENGINEERING.

First annual convention of the North Dakota drainage league: The International drainage conference (*Grand Forks, N. Dak.: Press Pub. Co., 1906, pp. 89*).—The report of the North Dakota Drainage League contains an address by Hon. J. L. Cashel suggesting the desirability of including drainage projects under the provisions of the National Reclamation Law; an address by G. A. Ralph in which he discusses drainage projects completed or under construction in Minnesota; a paper on the relation of the office of State engineer to drainage problems, by A. L. Fellows; an address by C. G. Elliott in which he treats of the need and value of drainage, its results in other localities, and its legal phases, particularly with reference to assessment for the expenses of drainage improvements and the avoidance of unnecessary litigation; and a paper by J. T. Stewart on the drainage problems of the Red River Valley as related to the Dakota side, in which the more technical phases of the question are discussed, with an outline of a scheme of drainage to give the best service at the least cost. Papers and addresses were delivered at the International Drainage Conference by Hon. J. L. Cashel, Prof. E. F. Chandler, Prof. W. R. Hoag, C. H. Dancer, of Manitoba, and G. A. Ralph.

Subsurface drainage of land by tile, R. E. HORTON (*Reprinted from Mich. Engin., 1906, pp. 22, figs. 8*).—This is an attempt to place upon a mathematical basis the determination of the amount of water removable by tile drains in a given time, their distance, and size. The treatise is based upon formulæ derived by Slichter for the flow of water through soils, which the author has adapted to the present purpose. These formulæ involve constants depending upon the porosity of the soil and the effective diameter of the soil grains. In order to make the formulæ applicable, the constants are given for a number of cases. The results of typical problems seem to check with successful prac-

tice, thus apparently conforming the author's idea that the problems connected with land drainage can be placed upon a fairly rational basis.

Drainage of tidal and swamp lands in South Carolina (*Engin. News, 56 (1906), No. 8, p. 194*).—This is a report of the drainage convention held in South Carolina, at which a paper was presented by Dr. E. Mead and C. G. Elliott, summarizing the results secured by this Office in its studies in South Carolina.

"It appears from facts given in the paper that large areas of rice lands, some of which have been in cultivation for a century or more, have been and others must be abandoned, or at least other crops substituted for rice; this is largely due to changes in river conditions, including lack of fresh water required for flooding the rice fields."

Three conditions are necessary to make the land suitable for cultivation:

(1) Strengthen the existing levees, rebuild those destroyed, and make them high enough to withstand floods.

(2) Ditch the inclosed lands, so that soil water can be removed to a depth of 3 ft.

(3) Install pumping plants to remove all such drainage water as can not be removed by gravity through sluices or trunks.

The entire drainage problem is summarized as follows: "The coastal section of the State must be drained before it will be sufficiently healthful to attract thrifty and intelligent farmers. This can be done in such a way as to make the country sanitary, with the exception of the river lands, for \$5 per acre, and for high-class cultivation for \$10 to \$15 per acre. The tidal river rice lands which are injured by salt water should be converted into drained fields and planted in upland crops. This may be done at a cost of \$15 per acre."

The relation of irrigation to dry farming, E. MEAD (*U. S. Dept. Agr. Year-book 1905, pp. 423-438*).—In this article the author discusses the question of so utilizing lands in the great semiarid belt of this country as to make them support the largest number of people while giving them the greatest measure of human comfort. The failure and lessons resulting from the first attempts to farm these lands are reviewed and the present reawakened interest described.

In connection with dry farming the writer considers a small irrigation plant a prerequisite of success, and three methods are given by which it is deemed possible to control enough water to irrigate from 1 to 10 acres of every dry farm: (1) Pumping from soil water or underground streams; (2) storage in small surface reservoirs of storm waters or the irregular flow of streams; and (3) irrigation with flood water, usually in the winter or spring. Each of these methods is discussed and existing successful examples given.

The following principal conclusions are drawn: (1) That the foundation of the dry farm should be mixed husbandry, in which stock raising is the leading feature. (2) The dry farm should have a larger acreage than either the irrigated or humid farm, particularly if irrigation is to be a feature of the dry farm. (3) There are few localities where enough water can not be had for the irrigation of 1 to 10 acres on each section. (4) Supplemental irrigation is the insurance of the dry farm whether the water is confined to intensive cultivation of a small tract or used in emergencies on larger areas.

The State engineer and his relation to irrigation, R. P. TEELE (*U. S. Dept. Agr., Office Expt. Stas. Bul. 168, pp. 99, fig. 1*).—This bulletin discusses the whole subject of public control of the use of water in irrigation, since in most of the arid States whatever there is of public control centers in the office of the State engineer. The matter is taken up by States in the order in which the office of State engineer was created.

The essential features of a system of public control of irrigation are: Some method of defining rights acquired before the assumption of control by the State; a procedure for the acquirement of rights, and an administrative system for distributing the water of streams to those entitled to its use. The laws of each State are discussed from these three standpoints. There is now fairly complete control of irrigation by the State in Wyoming, Nebraska, Idaho, Utah, Nevada, North and South Dakota, and Oklahoma, while Colorado, Montana, Oregon, and New Mexico have only partial provision for such control.

The bulletin sketches the history of irrigation legislation in each of these States and shows the efficiency of the laws enacted as demonstrated by experience.

Irrigation and the permeability of soils, A. MÜNTZ and L. FAURE (*Compt. Rend. Acad. Sci. [Paris]*, 143 (1906), No. 7, pp. 329-335; *abs. in Rev. Sci. [Paris]*, 5, ser., 6 (1906), No. 8, p. 242).—In this note the authors discuss the relatively slow development of irrigation in France.

Large enterprises backed by private capital are uniformly unsuccessful financially, due chiefly to the conservatism and ignorance of the farmers together with the change of habits and system of cultivation which the adoption of irrigated agriculture necessitates. Governmental control or aid in these enterprises is therefore recommended, and to break down the conservatism of the farmers and increase the acreage of land irrigated the authors advocate principally the division and sale of water by volume rather than by continuous flow during the season. To make it possible for the farmer to use the volume of water bought most advantageously, the writers propose a system of investigations into the permeability of soils, from which it will be possible to classify the soils with respect to their relative permeability. Experiments on the water requirements of soils of certain permeabilities are to be made, from the results of which it will be possible to predict the water requirement of soil of any degree of permeability.

The duty of well water and the cost and profit on irrigated crops in the Rio Grande Valley, J. J. VERNON, A. E. LOVETT, and J. M. SCOTT (*New Mexico Sta. Bul.* 56, pp. 52, figs. 3).—This bulletin contains the results of observations made during the seasons of 1903 and 1904 in cooperation with this Office.

Four subjects were investigated: (1) The relative value of well and river water for alfalfa; (2) the cost of growing alfalfa with well and river water; (3) the cost of growing wheat, corn, and sweet potatoes with well water; and (4) the determination of effects of temperature of irrigation water upon plant growth. From the results the following principal conclusions were drawn:

"No perceptible difference, due to a difference in the temperature of the water, was noticeable between the crops grown with well and with river water. The well water in New Mexico was 8.4° F. warmer on the average than Utah river water used for irrigation.

"The largest yield per inch of water was obtained when a depth of 24 in. was applied to wheat, and 39 in. to alfalfa, 5 cuttings of alfalfa being secured during the season.

"The results of these experiments have shown quite conclusively that the yearly profits may be considerably increased during years of shortage in the water supply by supplementing the river water with well water.

"Averaging the results obtained from crops grown with well water during the season of 1904, we have the following:

"(a) Depth of water required: Alfalfa, 36.4; wheat, 26.6; corn, 25.2; and sweet potatoes, 17.6 in.

"(b) Cost of pumping per acre: Alfalfa, \$10.50; wheat, \$9.80; corn, \$6.92; and sweet potatoes, \$4.91.

"(c) Cost of applying the water per acre: Alfalfa, \$1.23; corn, 85 cts.; and sweet potatoes, 64 cts.

"(d) The yield per acre: Alfalfa, 2.33 tons; corn, 31.9 bu.; and sweet potatoes, 10,000 lbs.

"(e) The value of the crop per acre: Alfalfa, \$35.03; wheat, \$18.09; corn (including the stover), \$36.27; and sweet potatoes, \$170."

Public roads: Mileage and expenditures in 1904 (*U. S. Dept. Agr., Office Pub. Roads Circs.* 39, pp. 2; 40, pp. 2; 41, pp. 3; 42, pp. 2; 43, pp. 3; 44, pp. 4; 45, pp. 4; 46, pp. 3; 48, pp. 4; 49, pp. 2; 50, pp. 2; 51 pp. 2; 52, pp. 2).—These are a series of leaflets issued by the Office of Public Roads, U. S. Department of Agriculture, in which road statistics are given by States. The present numbers include the States of Alabama, Arizona, Arkansas, Iowa, Maine, Maryland, New Hampshire, New Mexico, North Carolina, Oregon, Tennessee, Virginia, and Washington. For each of these States statistics are given by counties as to the total number of miles of public roads, together with those which have been surfaced, and the expenditure in money and labor as property and labor tax.

An experiment in dust prevention (*Engin. Rec.*, 54 (1906), No. 12, p. 311).—Experiments by the State engineer are being carried on near Troy, N. Y., on the prevention of dust on a road running through a village of considerable population, where the dust nuisance is very annoying.

The means employed are as follows: "Tar, of about the consistency of molasses when cold and fluid when heated, is sprinkled over the road surface. The low spots in the road are then filled with screenings, which are consolidated by the traffic before the second application of the tar is made. This process is repeated a third time, and is said to result in a practically dustless highway, which will not need another treatment for a year or more. The tar employed is specially prepared for the purpose by boiling until all its water has been driven off, so that it is not likely to foam when heated for application to the roads."

Tar and oil for road improvement: Report of progress of experiments at Jackson, Tenn. (*U. S. Dept. Agr., Office Pub. Roads Circ.* 47, pp. 8).—In this circular are reported results of experiments with coal tar, Texas oil and its residuums, in the improvement of macadam and earth streets and roads. The tar was applied during hot weather to the repaired, cleaned, and thoroughly dried surfaces of roads in and near the city of Jackson, Tenn. The tar was kept at a temperature of 200° while being conveyed over the roads in a tank wagon, from which it was distributed over the road surface by a hose with special nozzle and spread evenly in a thin layer by laborers using stiff brooms. The tar was absorbed by the road in 8 or 10 hours, after which a light coat of sand or screenings was evenly spread over the surface and the road rolled by steam roller. The average quantity of tar used per square yard was 0.45 gal. and labor cost \$0.0056 to \$0.0095 per square yard.

It is stated that "after more than 7 months, including the winter season of 1905-6, the tarred roads and streets are still in excellent condition. They are hard, smooth, and resemble asphalt except that they show a more gritty surface." By sections cut from the streets it was found that the tar formed a matrix of 1 to 2 in. in thickness, in which the individual stones were embedded. The tar is said to have antiseptic qualities, to make the road as dustless as asphalt, and to lessen greatly the noise of traffic.

In the experiments with oil on city streets, 0.48 gal. was used per square yard at a cost for labor of \$0.0057 per square yard. On the county roads the respective items were 0.38 gal. and \$0.0033. The oil was applied to the dusty

road surface and no subsequent treatment except spreading by brooms was given. The best results were obtained with heavier oils used hot. Dust is largely prevented on roads treated with the heavier oils, but the light, crude oil was found too volatile to produce permanent results.

The oiling and tarring of improved roads (*Engin. Rec.*, 54 (1906), No. 8, p. 197).—A discussion of means for abating the dust nuisance on country roads. The inefficacy of oil treatment when the oil is merely sprinkled upon the improved road surface is well shown, it being concluded that "oil treatment is decidedly worse than nothing, especially as the result, after a period of dry weather, is no less dust than before and certainly of a not less disagreeable character." When the road surface is swept clean and is perfectly free of dust, crude oil or tar treatment is suggested, but the fact is emphasized that the road surface must be clean and dry and traffic must not be resumed until the oil or tar is absorbed. This, it is stated, will prevent the raising of dust for a considerable period.

The concrete block industry as an adjunct to agriculture, E. FREUND (*Musch. Ztg.*, 4 (1906), Nos. 11, pp. 124-126, figs. 2; 12, pp. 133, 134; 13, pp. 145-147, figs. 6).—The writer describes a molding machine for the manufacture of concrete brick, and blocks for various uses; for example, cornices, lintels, arches, etc., together with a hand or power driven machine for the mixing of materials. The proportions of the various ingredients are given and also a discussion of the relative lengths of time of setting with different grades of cement. The total cost for the manufacture of 1,000 brick is given as \$2.65 using lime and cement, and \$3.20 using cement alone at the prices for the respective materials prevailing in Germany.

The number and distribution of silos in Wisconsin, G. N. KNAPP (*Wisconsin Sta. Rpt.* 1905, pp. 363-366, fig. 1).—A statistical record compiled from reports by assessors on the number of silos in the various counties of Wisconsin. The number of silos per county is found to be usually in direct proportion to the number of dairies. The total number reported for the State was 716.

Motor trucks and motors at the fifth automobile show, M. HARDY (*Ann Genblour.*, 16 (1906), Nos. 4, pp. 213-235, figs. 10; 6, pp. 359-385, figs. 9).—The writer describes a large number of power trucks, giving data as to their performance and structural details. He compares gasoline and steam motors in their application to motor trucks and finds that "if one considers the progress which has been made and the advantages of steam, steam motors should be in more favor than the other. So far as starting and changes of velocity are concerned, particularly for heavy trucks, steam motors possess an elasticity and pliancy which do not belong in the same degree to the internal combustion motor."

A so-called "energy-car" is described, which is designed especially for use in agricultural operations. It consists of a light wagon carrying an explosion motor coupled to an electric generator by a special device. The generator is so wound that it may operate either as generator or motor, and it is connected to a small storage battery carried by the wagon. The batteries furnish an additional power when the load is greater than the explosion motor can develop normally. By the entire combination a flexibility of control, ease, and certainty of operation are obtained which would not be possessed by the explosion motor alone, to which are combined the advantages that it may deliver mechanical energy at the wagon or electrical energy at a distance to be used for power or electric lighting.

With reference to the economy of different types of motor, the writer regards the motors of the automobile type much less economical and durable than other types of motor due to their high velocity of rotation and greater cylinder

wear due to short length of connecting rod. They are, however, cheaper in first cost than other types. The author states that gasoline motors furnish power at 0.141 franc per 100,000 kilogrammeters (2.7 cts. per 723,240 ft. lbs.).

Accidents by farm machinery, G. N. KNAPP (*Wisconsin Sta. Rpt. 1905*, pp. 367-373).—Statistics relating to the number of persons injured or maimed in the operation of farm machinery are presented.

From the figures given it is found that accidents resulting from the use of corn shredders "are in the majority of cases serious. Twenty-eight per cent are fatal, 50 per cent result in cripples by the loss of arms or hands, and 23 per cent of the accidents result in partial cripples by the loss of fingers. In 1904 16 persons lost arms in corn shredders to 10 persons who lost arms in all other machinery combined."

Attention is directed to the great care necessary in the operation of corn shredders, and the law relating to the equipment of such machinery with safety devices is given.

Alcohol in gasoline engines, E. W. LONGANECKER (*Farm Implements*, 20 (1906), No. 6, p. 40).—In an article originally appearing in *Gas Power* the writer gives the results of some preliminary experiments on the use of alcohol in gasoline engines. He thinks that the average compression pressure for alcohol should be somewhere between 90 and 120 lbs. per square inch, and advises increasing the length of the connecting rod or making such changes in the compression space as will bring about this pressure. It was found that while the engine could be started by the use of alcohol alone by spraying the latter into the inlet pipe, it was much more satisfactory to use gasoline for the first 12 or more impulses.

Denaturized alcohol in France (*Sci. Amer. Sup.*, 62 (1906), No. 1599, pp. 25613-25615, figs. 4).—In this article the writer considers chiefly the denaturizing agents employed in France, comparing the kinds and proportions with those used in other countries.

The official denaturant in use in France at the present time consists of 1.0 part of methyl spirit (wood alcohol) and 0.5 part standard benzine to be added to every 100 parts of alcohol. The denaturants may vary under official license, with the particular use to which the product is to be put. For use in internal combustion engines, about 50 per cent of benzine is added, which increases the calorific power of the alcohol to about 7,850 calories—nearly the same value as for gasoline. The denaturants have been found unsatisfactory, especially when used in engines, and the French Government offers a prize of \$4,000 for a denaturant which renders the alcohol unfit for drinking yet without objectionable odor, which will not separate by fractional distillation or erode the metal parts of lamps or motors, which will not be poisonous, but which may easily be detected. A second prize of \$10,000 is offered for an apparatus which will allow alcohol to be used for lighting in the same manner as is petroleum.

The apparatus used in the denaturizing process is illustrated and described. It is said that the process is a most simple one, requiring no heating or like apparatus.

RURAL ECONOMICS.

Causes affecting farm values, G. K. HOLMES (*U. S. Dept. Agr. Yearbook 1905*, pp. 511-532).—Based on inquiries addressed to 45,000 correspondents throughout the United States, the causes which have influenced the increase in value of farm lands and improvements since the census of 1900 are summarized and discussed.

This increase since 1900 is estimated at 33.5 per cent on the value of all farm property, or \$6,131,000,000 for the 10 classes of farms as grouped by the Census.

"The rate of increase for cotton farms is highest, 48.2 per cent . . . and the lowest of all [are] the dairy farms, with an increase of 25.8 per cent." The most important causes assigned in explanation of this increase of farm values are the increase in prices received for farm products during the past 5 years and the pressure of new demand for land upon a fixed area. Incidentally, however, very large effects in increasing values "have been derived from better cultural methods, from the substitution of profitable for unprofitable crops, by the adoption of more intensive culture and crop, by better applied labor, by larger and cheaper facilities for reaching markets, and by some improvements in the business features of marketing products. Each one of these causes is of large account and all together combine to make the net return per acre larger than it was 5 years ago by an amount sufficient to raise the capitalization of farm lands in a considerable degree."

The influences affecting both the increase and decrease of farm real-estate values are itemized and grouped according to the economic phenomena and conditions most noticeable throughout the North Atlantic, South Atlantic, North Central, South Central, and Western groups of States. These conditions are giving rise to movements in population which tend to raise values where they are most needed, namely, in the South, in the semiarid regions of the West, and in "the depressed East." The author points out the importance of the adjustment of urban and rural populations in promoting national welfare, and concludes that "high prices of lands necessarily require that there shall not be too large a percentage of total population engaged in agriculture, and the nonagricultural population must be prosperous so as to pay profitable prices for agricultural products."

Agriculture in the United States, J. J. MACFARLANE (*Com. Amer.*, 3 (1906), No. 1, pp. 6-8, *dgnms.* 3).—Statistics relating to the increased yields and values of staple agricultural products are reported and discussed, the data being compiled in great measure from the census of 1900 and from the publications of this Department for the years 1900 to 1905, inclusive. The economic factors contributing to the great development of the agricultural wealth of the United States are also enumerated.

The world's agriculture, J. J. MACFARLANE (*Com. Amer.*, 3 (1906), No. 3, pp. 10-12, *dgnms.* 3).—By means of diagrams the author discusses the relative proportions of land of the world's leading nations that are devoted to cereal production, to pasture, and to forests, as well as the extent of cultivated, cultivable, and waste land in each country.

Statistics are presented of the present population of the various countries and of the world's cereal production in 1905. The average yields of leading cereals for the five years 1901-1905, expressed in millions of bushels, are as follows: Oats, 3,371; wheat, 3,160; corn, 2,896; rye, 1,581; barley, 1,330. From a study of all the data presented the author believes that no nation at present is equal to the United States in agricultural area or wealth, and that there is very little prospect of any being so in the near future.

The value relations of buildings, live stock, and implements to fixed capital, CLAUSEN (*Jour. Landw.*, 54 (1906), No. 3, pp. 217-234).—The author defines fixed or basic capital (*Grundkapital*) as the combined value of land and buildings, and discusses the value relation to each other of the different elements of capital invested in agriculture.

The Province of Schleswig-Holstein is divided into 5 groups according to certain definite characteristics of the land, and statistics are presented of each group which show the relation of cultivated area to total area; the estimated value of estates not including improvements; the percentage of investments in buildings, live stock, and implements; the value per hectare of total area in-

cluding buildings; and the value of buildings, live stock, and implements per hectare of total area and per hectare of cultivated area.

Rural credit institutions: Mutual funds, P. GILLIÉRON-DUBOIX (*Institutions rurales de crédit: les caisses mutuelles. Lausanne: P. Fatio, 1906, pp. 103*).—In this work the author treats in detail of the origin, development, and aims of agricultural credit institutions in Belgium, Germany, Italy, France, and Switzerland, with brief notes on the present status of such organizations in a few other European countries.

The history of the different forms of mutual societies for raising and advancing loans to agriculturists is considered. The aim of the author is to give to agriculturists of Switzerland, and particularly to those of the Canton de Vaud, precise information concerning the best method of organizing and dispensing agricultural credit. The methods practiced in France are regarded as giving the most favorable results.

In a series of appendixes the author gives specimen by-laws of a Raiffeisen society, of local and district mutual agricultural credit societies of France, and of a mutual rural society of the Canton de Vaud.

Crop Reporter (*U. S. Dept. Agr., Bur. Statist. Crop Reporter, 8 (1906), Nos. 5, pp. 17-24; 4, pp. 25-32; 5, pp. 33-40*).—These numbers for July, August, and September, 1906, contain in addition to the usual statistics on the condition of crops in the United States and foreign countries the following special articles: Tobacco acreage and condition July 1, 1906, by types; exports of durum wheat, 1905-6; exports of farm and forest products in 1906; adulteration of alfalfa seed; alcohol production in the German Empire; imports of farm and forest products in 1906; and other topics relating to agricultural statistics.

Agricultural statistics, 1905 (*Bd. Agr. and Fisheries [London], Agr. Statist., 1905, pp. LXI+306*).—This publication contains complete returns of acreage under crops and grass and number of live stock in each county of Great Britain for the year ended June 5, 1905.

Statistics are also given on the value of land; returns of produce and yield per acre; prices of wheat, barley, oats, bread, live stock, and other agricultural produce; trade in live stock with Ireland; supply of cattle, sheep, and pigs at certain markets; agricultural imports and exports of the United Kingdom; and on the weather of Great Britain. Indian, colonial, and foreign agricultural returns are included and compared.

Agricultural returns of Great Britain, 1906 (*Bd. Trade Jour. [London], 54 (1906), No. 510, pp. 454, 455*).—A summary is given of the acreage under crops and the number of live stock in Great Britain on June 4, 1906, in comparison with similar data for the year 1905.

AGRICULTURAL EDUCATION.

Agricultural education, J. S. STEWART (*Athens, Ga.: Author, 1906, pp. 7*).—Condensed report of an address before the Georgia Educational Association, June 22, 1906. The three tests—usefulness, furnishing mental discipline, and having cultural value—are applied to the subject of agriculture to determine whether it is worthy a permanent place in the curricula of schools and colleges. The writer believes that it meets all of these tests and outlines a scheme for agricultural schools in Georgia.

The educational element in agriculture, J. M. COLSON (*South. Workman, 35 (1906), No. 9, pp. 504-507*).—An address before the Virginia State Teachers' Association, in which a discussion is given of the educational value of agriculture and a plea made for its introduction into public schools.

Agriculture (*Manual and Guide and Course of Study for the Common Schools*

of South Dakota. Mitchell, S. Dak., 1906, pp. 147-163).—This is a course of study prepared by J. W. Wilson, N. E. Hanson, and W. A. Wheeler, and consists mainly of general exercises and observations.

Elements of agriculture (*Manual of the Elementary Course of Study for the Common Schools of Wisconsin*. Madison, Wis.: State Supt. Pub. Schools, 1906, pp. 222-236).—This course in elementary agriculture for the public schools of Wisconsin is divided into agriculture (agronomy), farm animals, and farm poultry. Under agronomy the following topics are discussed: Aims, the soil, water and the soil, tilling the soil, soil enrichment, the plant, the leguminous plants, plant enemies, rotation of crops, selection of seed, the farm garden, weeds, and home and school gardens. Under farm animals, care and feeding, type forms, and farm economics are considered.

Elementary agriculture with practical arithmetic, K. L. HATCH and J. A. HASELWOOD (*Chicago: R. K. Row & Co., 1906, pp. 207, pt. 1, figs. 47*).—This is a text-book of agriculture suitable for use in elementary rural schools. It treats in a brief but logical way of plant and animal production and devotes some space to farm mechanics and economics.

The plan of treatment is indicated by the following subjects of chapters: Why plants grow, the plant and the water, plant foods, soils, the soil and the crops, wearing out the soil, legumes, tilling the soil, draining the soil, the crop, insects and diseases that injure the crops, the fight against weeds, the stock on the farm, feeding the stock, the three c's—cows, corn, and clover, the dairy, poultry, some special crops, farm buildings, farm accounts, forestry, home and school grounds, school gardening, and home gardening. There is also an addendum containing plans for the construction and ventilation of barns and score cards for judging corn, beef cattle, dairy cattle, draft horses, swine, and mutton sheep.

The feature which distinguishes this text-book from any other that has appeared in this country is the nature of the practicums, which consist of problems in agricultural arithmetic. There is a total of 274 of these problems, of which there are from 6 to 24 following each chapter and related to the subjects discussed in that chapter. There are also scattered through the text numerous tables taken from the publications of this Department and adapted to the needs of the text-book, as well as numerous references to the bulletins and other publications of this Department.

Teaching horticulture in public schools, E. V. HALLOCK (*Amer. Florist*, 27 (1906), No. 951, pp. 216, 217).—This is a report of a special committee of the Society of American Florists, presented at the meeting of the society in Dayton, Ohio, August 21, 1906. In it are discussed such matters as text-books, standardizing courses of study, instructions to teachers, lectures, and children's garden conferences. A plan for garden work and instruction in horticulture is given in outline form.

The use of illustrative material in teaching agriculture in rural schools, D. J. CROSBY (*U. S. Dept. Agr. Yearbook 1905, pp. 257-274, pls. 3, figs. 10*).—In this article the writer discusses the value of agriculture in rural schools, describes methods employed in teaching this subject in a consolidated school in Tennessee, in a village high school in Pennsylvania, and in a country high school in Kansas, describes 8 exercises which can be performed with simple and inexpensive apparatus, and discusses agriculture as an aid to other school work.

Nature study and elementary agriculture for the elementary public schools, A. C. TRUE and D. J. CROSBY (*West. Jour. Ed.*, 11 (1906), Nos. 4-7, pp. 8-24).—This article was prepared at the request of a committee appointed at a meeting of the State Teachers' Association and the State Farmers' Institute at Berkeley, Cal., December 26-29, 1905, and is intended to show in some detail

the topics which should be included in nature study and elementary agricultural instruction and the methods which should be followed in this work. It was prepared to meet the conditions existing in California schools, and is divided into 5 parts to correspond to the grouping of grades already recognized in that State, viz, nature study for Group I (grades 1-3), nature study for Group II (grades 4-6), and elementary agriculture for Group III (grades 7 and 8). The topics to be discussed in nature study and elementary agriculture are given in the order of treatment recommended, and the use to be made of school gardens and other practicums is discussed. A number of practicums are outlined, and lists of books and other publications on nature study, school gardens, and elementary agriculture are given. The references to works on elementary agriculture are arranged according to the divisions of this subject, viz, plant production, animal production, dairying, rural engineering, and rural economies.

The foundations of chemistry as seen in nature study, J. BRITAIN (*Ottawa Nat.*, 20 (1906), No. 3, pp. 89-92).—Simple experiments with wood, sugar, starch, and other carbohydrates to illustrate chemical union and show the presence of carbon and water in these substances.

MISCELLANEOUS.

Yearbook of the Department of Agriculture, 1905 (*U. S. Dept. Agr. Yearbook 1905*, pp. 815, pls. 73, figs. 139).—The Yearbook for 1905 contains a report of the Secretary on the work of the Department during the year, 30 special papers abstracted elsewhere in this issue, and an appendix consisting of an agricultural directory, a review of the progress in different lines of agriculture, and agricultural statistics.

Some ways in which the Department of Agriculture and the experiment stations supplement each other, E. W. ALLEN (*U. S. Dept. Agr. Yearbook 1905*, pp. 167-182).—The more important features of the Department and experiment station work are briefly set forth. The survey shows that while some lines of work are being carried on primarily by the Department, some by the stations, and some by the two agencies working in cooperation, there is, in the words of the author, a mutual interdependence which has affected the work of both to a very great degree and has contributed materially to its scope, efficiency, and application in practice.

Report on agricultural investigations in Alaska, 1905, C. C. GEORGESEN (*U. S. Dept. Agr., Office Expt. Stas. Bul. 169*, pp. 100, pls. 8, fig. 1).—This is a report on the several lines of work which have been carried on during the year at the Sitka, Copper Center, Rampart, and Kenai stations. Extensive tests have been made with field and horticultural crops, and some work with live stock has been undertaken. In addition to the results of experimental work noted elsewhere in this issue, notes are given on weather conditions in Alaska, the reservation at Fairbanks, the number of homesteads in Alaska, imports of farm products into Alaska, the forests in the interior of the Territory, and on other topics.

Report on agricultural investigations in Hawaii, 1905, J. G. SMITH (*U. S. Dept. Agr., Office Expt. Stas. Bul. 170*, pp. 66, pls. 4).—This consists of a general review of the work of the station during the year, results of experiments with tobacco and other crops, and reports of the chemist, entomologist, and horticulturist. The experimental work is for the most part noted elsewhere in this issue.

Report on agricultural investigations in Porto Rico, 1905, D. W. MAY (*U. S. Dept. Agr., Office Expt. Stas. Bul. 171*, pp. 47, pls. 7).—This contains a brief summary of the results of experiments with various crops, notes on live

stock in Porto Rico, and reports of the entomologist and botanist, the horticulturist, and the coffee specialist. The experimental work is noted elsewhere in this issue.

Nineteenth Annual Report of Arkansas Station, 1906 (*Arkansas Sta. Rpt. 1906, pp. VIII+77-210*).—This includes the organization list of the station, a brief report of the director, giving the subjects of the bulletins issued during the year, a financial statement for the fiscal year ended June 30, 1906, and reprints of Bulletins 88-91 issued during the year.

Eighteenth Annual Report of Massachusetts Station, 1905 (*Massachusetts Sta. Rpt. 1905, pp. 254*).—This includes the organization list of the station, a report of the director, a financial statement for the fiscal year ended June 30, 1905, and departmental reports abstracted elsewhere.

Nineteenth Annual Report of Nebraska Station, 1905 (*Nebraska Sta. Rpt. 1905, pp. 117*).—This contains the organization list of the station, a review of the work of the station by the director, a financial statement for the fiscal year ended June 30, 1905, and miscellaneous articles abstracted elsewhere.

Fifteenth Annual Report of Oklahoma Station, 1906 (*Oklahoma Sta. Rpt. 1906, pp. 13-63*).—This contains a report of the director, a summary of the press bulletins issued during the year, meteorological observations noted elsewhere, and a financial statement for the fiscal year ended June 30, 1906.

The press bulletins are to a large extent a repetition of matter published in the regular bulletins of the station. The subjects treated include: Hardy Bermuda grass, Bermuda hay, wheat experiments, pasturing wheat 1904-5, harvesting cowpeas, destroying weevils in cowpeas, soy beans as a catch crop, storing sweet potatoes, small fruits, planting trees, pear blight, spray for profit, fungicides, insecticides, remedies for chinch bugs, poisoned bran for cutworms and grasshoppers, the cotton square borer, soil inoculation, blackleg vaccine, and horse breeding.

Annual Report of Pennsylvania Station, 1905 (*Pennsylvania Sta. Rpt. 1905, pp. 236*).—This contains the organization list of the station, a financial statement for the fiscal year ended June 30, 1905, a report of the director on the work of the station during the year, and departmental reports, parts of which are abstracted elsewhere. The report also contains reprints of Bulletins 71-75 of the station, already noted, and of an article on the energy value of red clover hay and corn meal (*E. S. R., 17, p. 579*).

Twenty-second Annual Report of Wisconsin Station, 1905 (*Wisconsin Sta. Rpt. 1905, pp. 397*).—This contains the organization list of the station, a report of the director, including a subject list of station publications, numerous articles abstracted elsewhere, lists of exchanges and acknowledgments, and a financial statement for the fiscal year ended June 30, 1905. Two articles are reprinted from Bulletin 129 of the station (*E. S. R., 17, p. 498*).

Accessions to the Department Library, April-June, 1906 (*U. S. Dept. Agr., Library Bul. 60, pp. 64*).

NOTES.

Georgia Station.—Martin V. Calvin, of Richmond, Ga., has been elected to succeed R. J. Redding as director.

Kansas College and Station.—According to the *Industrialist*, J. E. Payne has been selected to take charge of the station at Garden City, to be conducted in cooperation with this Department. The college has a total enrollment of 1,356, a gain of about 200. The State legislature will be asked to appropriate \$670,500 for the next biennium. Of this amount \$295,000 is for current expenses.

Louisiana Stations.—Fritz Zerban, Ph. D. (Munich), has succeeded to the place of Dr. C. A. Browne, jr., as chemist at the sugar station. R. C. Holtzelaw, formerly assistant chemist at the State station, has been recently appointed assistant to the State chemist of Georgia.

Maine University and Station.—Percy Campbell has been appointed assistant in animal husbandry.

Massachusetts College and Station.—M. A. Blake, assistant in horticulture, has resigned to become horticulturist at the New Jersey State Station. The vacancy previously noted, caused by the resignation of F. G. Helyar, has been filled by the appointment of W. K. Hepburn.

Michigan College.—The campus has been extended by moving all of the older barns back 200 or 300 yards to an elevated position on the river bank. It is proposed eventually to erect a new agricultural building on the site thus vacated. A new engineering building is in process of erection. It is to consist of a stone and brick basement, above which will be four stories of vitrified brick, trimmed with white sandstone. This is to contain class rooms and laboratories for the departments of mathematics, physics, drawing, and civil and mechanical engineering. The old mechanical building will be devoted to shopwork.

Plans are being perfected for a jubilee week next spring to celebrate the fiftieth anniversary of the opening of the first agricultural college in the United States. It is now proposed to hold the jubilee May 28-31. A programme is being arranged so that the delegates to the Association of American Agricultural Colleges and Experiment Stations, which it is hoped will meet in Lansing at that time, may attend all of the more important sessions of the jubilee. President Roosevelt will speak May 31, and the college is planning to entertain from 10,000 to 15,000 people on that day.

Minnesota Station.—A. D. Wilhoit has been appointed assistant in soil investigations, and George Craig assistant in animal breeding experiments.

Mississippi College and Station.—D. C. Mooring has been appointed assistant in horticulture. E. R. Lloyd is to have charge of the farmers' institute and extension work. J. W. Fox has been put in charge of the Delta substation and C. T. Ames of the Holly Spring station.

Nebraska University and Station.—Martin Nelson has been appointed instructor in field crops and soils in the university and assistant in crops in the station.

New Hampshire College and Station.—Harry F. Hall, formerly assistant in horticulture, has been appointed horticulturist to succeed F. W. Rane, whose resignation has been previously noted.

Cornell University and Station.—Charles H. Tuck, a graduate of the university in 1906, has, according to the *Cornell Countryman*, been appointed supervisor of the farmers' reading courses, vice G. W. Horsford, who has entered the employ of this Department. Henry Jennings, a former student, is reported as having accepted a position as poultryman at the Maryland Station. Dr. C. H. Roberts, a practicing dentist of Ulster County, N. Y., has recently endowed five scholarships in the College of Agriculture, donating \$30,000 for the purpose.

Oregon College and Station.—C. E. Bradley, formerly head of the chemical department of Pacific University, has been appointed assistant chemist in the station, and W. H. Wicks, a graduate of the Oregon College, has been appointed assistant horticulturist. A contract has recently been let for the erection of a women's building, to cost \$71,300.

Virginia College and Station.—Dr. J. M. McBryde has been tendered a pension under the retirement fund of the Carnegie Foundation for the Advancement of Teaching. It is reported that he will retire at the close of the present college year.

The director and several members of the station staff were charged with the management of the live stock department of the State fair, recently held at Richmond. The station made an exhibit of potatoes, tobaccos, and cereals in the grain and straw, which attracted a great deal of attention. A working dairy was also operated during the fair.

Armour Agricultural Scholarships.—J. Ogden Armour has offered to the president of the International Live Stock Exposition the sum of \$5,000 to be distributed annually at the exposition in 20 agricultural scholarships to be competed for by the State agricultural colleges at the exposition. In a letter to the president of the exposition he states that these scholarships are given in recognition of the work done by the agricultural colleges "in advancing the cause of agricultural education in this country through the character and extent of their exhibits of live stock and field products at the international show."

The competition is to be based upon the animal and grain exhibits from the several colleges and such other forms of agricultural student competition as may be recognized or established by the exposition. The details are to be determined by the management, and the scholarships are to be known as the J. Ogden Armour scholarships. The gift has been accepted by President Spoor.

Meeting of the International Congress of Applied Botany.—A meeting of the committee on applied botany, appointed by the Botanical Congress of Vienna in 1905, was held in Paris August 25 and 26, 1906, for the purpose of organization and formulating plans for investigation. The committee adopted as a preliminary programme a resolution providing for the appointment of a competent investigator to visit all parts of the world and study what has been done in applied botany along the lines of agriculture and horticulture, and the methods and facilities of such investigations. This inspection is to be made and a report submitted at the next meeting of the association in 1908. To meet the expense of this trip the committee undertakes to raise a fund of \$4,000 by subscriptions from societies and individuals interested in the various lines where botany touches upon agriculture and horticulture. The choice of the traveling inspector was left to a committee consisting of Messrs. Fruwirth, de Jacewski, Marchal, Ph. de Vilmorin, and Trabut.

A second committee, consisting of de Jacewski, Proost, Schillersky, Trabut, and Briel, was appointed to make a study and report upon the legal means adopted by all countries to prevent the introduction and spread of plant para-

sites. A zoologist is to be added to this committee, and insect pests will be included in the report.

Professor Flahault accepted a commission to prepare a catalogue showing regions of similar climatic conditions as indicative of their possibilities in applied botany.

Southeastern Iowa Short Course.—Special arrangements have been made for short courses in corn and live-stock judging and domestic science, to be held under the management of the Young Men's Christian Association in its new building at Mount Pleasant, Iowa, December 17–22. The Iowa Agricultural College will cooperate with those having the course at Mount Pleasant in charge. The classes in live-stock judging will be conducted by Professors Curtiss and Bliss, of Ames, in the new pavilion at the fair grounds, and the corn judging will be in charge of Professor Holden and assistants. During the week lectures will be given by President Storms and Doctor McNeil, of Ames, G. M. Rommel, of this Department, and others.

Agricultural Education in Hungary.—New regulations for the Royal Hungarian Horticultural School at Budapest provide that only applicants 20 years old or more, who have finished the sixth grade in public schools and have had one year of practical experience in gardening, can be admitted. Among the technical subjects taught in the course are garden architecture, machines and implements, landscape gardening, garden management, agriculture, farm economics, and farm law.

The agricultural academy at Magyar-Ovar is so crowded that it is recommending students to go to other agricultural academies in Hungary where the qualifications for admission to the Magyar-Ovar Academy will admit them to the second year.

School for Meadow Culture in Austria.—A meadow culture school was opened at Eger November 1, which is temporarily in charge of Franz Lindner, director of the agricultural school at Eger.

Forestry at Oxford.—A three-year forestry course is now provided at Oxford. Two years of the course are spent at the university and the third year on the Continent. Candidates for the Indian forest service are selected partly by examination held by the civil service commissioners and partly by nomination. Candidates who have taken the full course and secure appointments receive about \$1,500 the first year, and the grading is such that the final salary may reach \$10,000 a year. At the end of twenty-two years Indian forest officers can retire on a full pension, the maximum being about \$2,500 per year.

Butter Competitions.—According to the *Journal of the Board of Agriculture*, the department of agriculture for Ireland has been holding a novel form of dairy competition during the past few years. The butter exhibited at such competitions is arranged for by telegrams dispatched by the department on the morning of the day on which the exhibits are to be held. The competitors are unaware of the dates, and the constant daily attention which must accordingly be given the work is one of the principal advantages which accrue from this system.

Allotments to Agricultural Laborers in Denmark.—The Danish Government has recently undertaken an inquiry into the results obtained from the act of 1899 as amended in 1904. Under this act laborers who are able to provide suitable buildings, stock, implements, etc., may borrow from the state sums equal to nine-tenths of the mortgage value of the property to be obtained. The interest on the loan is 3 per cent, and no principal can be paid during the first five years. After that 4 per cent is to be paid on two-fifths of the loan for interest and principal, and the remainder of the loan is to be repaid later at the same rate.

During the five years in which the act has been in operation 1,859 allotments were acquired in this way, with loans amounting to \$1,815,000. The great majority of the owners were agricultural day laborers, and the total area of their holdings amounted to 14,552 acres, or nearly 8 acres each. The majority of the holders were members of cooperative societies, nine-tenths being members of cooperative dairies, one-third members of bacon-curing societies, and one-fourth members of societies for the cooperative sale of eggs.

Miscellaneous.—The annual meeting of the New York State Association of School Commissioners and Superintendents was held at Cornell University October 3 to 5. Considerable attention was given to a discussion of the best means of adapting rural schools to their environment. The consensus of opinion was that such schools should not teach agriculture separately, but as a part of the general scheme of pedagogy, of which it should be the basic factor.

Mark Lane Express states that negotiations are now proceeding whereby the Midland Agricultural College of Leicestershire is to be converted into a college of agriculture of the proposed Nottingham University. Authority will then be granted to confer degrees, which is not now permitted.

It is learned from the same source that the agricultural department of Leeds University is endeavoring to revive interest in the canning industry. Lectures are being given by a member of its staff on the canning and preserving of fruit in various centers in the vicinity.

At the celebration of the 400th anniversary of the foundation of the University of Aberdeen a new block of buildings, costing over \$1,000,000, was formally opened by the King. The buildings include extensive class rooms and laboratories for agriculture.

The October number of *Forestry and Irrigation* states that R. C. Bryant, for some time in charge of the cooperative work of the office of Forest Extension, of the Bureau of Forestry, has recently resigned to assist in organizing the work in connection with the chair of practical forestry and lumbering at the Yale Forest School. This chair was established by subscriptions from leading lumbermen throughout the country.

J. B. Mowry has been appointed commissioner of forestry in Rhode Island.

J. J. Dearborn, of the Harvard Forestry School, has become assistant to F. W. Rane, State forester of Massachusetts.

The death of B. Chauzit, director of the Departmental Agricultural Laboratory, at Nimes, and since 1882 departmental professor of agriculture in Gard, is noted in a recent number of *Progrès Agricole et Viticole*.

EXPERIMENT STATION RECORD.

Editor: E. W. ALLEN, Ph. D., *Assistant Director.*

SUBJECT LIST OF ABSTRACTS.

AGRICULTURAL CHEMISTRY.

Methods of determining phosphoric acid in artificial fertilizers, Christensen	307
Rapid analysis of superphosphates, Jacquet, Quintanilla, and Arredondo.....	307
Causes of error in citro-mechanical method in phosphates and slag, Pellet....	307
Determination of phosphoric acid as magnesium pyrophosphate, Schmitz	308
Should one titrate calcareous marl with sulphuric acid? Schulze.....	308
Determination of organic matter in waters by potassium permanganate, Garcia..	308
Detection of humus substances in water, Klut.....	308
New method for quantitative estimation of pentosans, Jolles.....	308
Uniform methods of analysis of cane-factory products, Pellet.....	308
Accurate commercial method for analysis of sugar beets, Davoll.....	308
Estimation of glucose by volumetric method, Watt.....	308
Analysis of milk under sale of food and drugs acts, Richmond and Miller.....	309
Refractometric determination of milk fat, Löwe.....	309
A modification of the salt method, Rusche.....	309
Determination of acidity in cream, Hesse-Güstrow.....	309
Determination of fat in cheese, Weibull.....	309
Determination of soluble and insoluble volatile fatty acids, Delaite and Legrand..	309
Use of chromed hide powder in determination of tannin, Nihoul.....	310
Examination of some Western Australian barks, Mann and Cowles.....	310
[Chemical work for agricultural department of Western Australia], Mann....	310
Practical methods for identifying and estimating boric acid, Prescher.....	310
Pure food, drug, and paint law, Ladd.....	310
Pure food, pure drug, formaldehyde, Paris green, and paint laws, Ladd.....	310

METEOROLOGY—WATER

	Page.
Monthly Weather Review, Vol. XXXIV, Nos. 5, 6.....	310

NOTE.—The publications of the United States Department of Agriculture, except those of the Weather Bureau, may be purchased from the Superintendent of other technical publications are given in the list above. The publications of the requests and remittances should be directed to the Chief of the Bureau. The price of the Record is \$1 per volume, or 10 cents per number. The prices of other technical publications are given in the list above. The publications of the State experiment stations are distributed from the stations and not from the Department.

EXPERIMENT STATION RECORD.

VOL. XVIII.

DECEMBER, 1906.

No. 4.

The convention of the Association of American Agricultural Colleges and Experiment Stations at Baton Rouge was one of unusual interest, especially to experiment station officers. The chief center of interest was the Adams fund, its aims and limitations, and the general policy regarding its use.

There was a broad discussion of the subject of research work, its relation to the other activities of the experiment stations and to the general public. At no previous meeting has there been so full and intelligent consideration of this subject and of the distinctive features of research and investigation. It did much to clarify views and elevate ideals, if it did not always relieve the feeling of pressure on the part of some that the needs and demands of their constituents should be met in a direct way. Such, however, could hardly fail to have carried away a clearer impression of the desirability of agricultural research and of its practicability as well.

The broad field and duty of the experiment station as a scientific institution was emphasized—its relations to agricultural education and to the promotion of agriculture in a broad sense, as well as to the local needs of the farmer. The need of a definite policy for every station and of adherence to its policy and programme of work was made evident, a need which is especially urgent at the present juncture.

The report of the new standing committee on station organization and policy was received with special interest. This committee is made up of a representative body of station men, headed by Dean Davenport as chairman. It has held several meetings during the year and has given careful and intelligent study to questions relating to the policy of the stations toward the Adams fund. Its conclusions are therefore entitled to much respect, and should have great weight in formulating the sentiment of the American stations.

While the committee deemed it impracticable at this time to determine in detail the kinds of work proper under the new fund, it laid down the following broad proposition: "It is evidently the inten-

tion of the Adams Act to provide the means for carrying on investigations of a relatively high order, with a view to the discovery of principles and the solution of the more difficult and fundamental problems of agriculture. To this end it is very desirable that careful attention shall be given to the choice of definite problems to be studied and the methods by which the solution of these problems is to be sought. Investigations in connection with which there is good reason to expect the establishment of principles of broad application should be preferred to those which have only local or temporary importance, or from which only superficial results are to be obtained."

The greatest evident difficulties in planning work under this new act were shown by the data collected by the committee to be (1) a lack of clear discrimination between investigation in a strict sense and the ordinary experimental work, (2) a lack of definiteness in the purpose and plan of the investigations, (3) a tendency to take up too large or broad problems, and (4) the outlining of too large a number of projects. "In the abstract everybody agrees with the purpose of the Adams Act and the desirability of restricting the fund closely to original investigations. When we come to concrete cases, however, there is very great difference of opinion." This was attributed in part to a habit of mind which has led to the designation of relatively simple experiments and tests as "investigations," although evidently not so in any real sense, and to a biased judgment which places undue stress upon demonstration work and the attainment of immediately practical results. Upon the latter point the committee said:

"The mental attitude of many of our station workers is wrong. They see only the immediate duty of the station to the local farmer of to-day. They forget that the station has a duty to all phases of agriculture in a broad sense, and that this may lead to much more permanent and widespread benefit. The development of agricultural education has come very largely as a result of station work. The stations have furnished the stock in trade of the agricultural instructor, and their work has been the means of putting agricultural instruction on a better pedagogic basis. They owe a duty to agricultural education and agricultural science which it is very important should be more generally recognized. The Adams fund will enable them to more largely meet this duty, and at the same time to lay a broader and more substantial basis for the science as well as the art of agriculture. In most States this new fund can safely be used for investigation which will not necessarily give an immediate return to the farmer, for the other funds will usually take care of the demands of the farmer sufficiently to keep him satisfied."

This is a broad conception of the stations' mission. Without disparaging any form of activity in the aid of agriculture, it calls atten-

tion to a too narrow view, which has often obscured our vision and had a noticeable effect upon the station workers themselves. In this it has struck a very vital part, for the aim and work of a station are determined in large measure by the men composing its staff. The commanding position of the man as the most important factor in research was strongly emphasized by the committee, and almost as a corollary to this it was urged that "the man and his line of work must be suitable to each other."

The latter is an important item which in the exigencies of station work has not always been given due consideration. It recognizes that men have special qualifications which should be discovered and encouraged. It is useless to try to exact research from a man whose interest and ability lie in demonstration and extension work, and it is a waste of good material to require extensive institute work of an investigator who has little heart in institute work and finds it uncongenial. While most stations can as yet specialize and differentiate to only a limited degree, they can in large measure relieve their research men of duties which are onerous to them, and utilize them more largely and more advantageously in lines in which their special qualifications and special interests lie.

Regarding the training of station workers, the committee held it to be "more important that a man be thoroughly educated in the fundamentals of science than that he be trained in some of its applications," since the man of thorough scientific training can readily acquire the known facts and point of view in the agricultural application of the science, while the other hopelessly lacks the basal knowledge of the science.

The high ideals set forth by this committee received the approval of the association in the adoption of the report, and the discussion of it was in accord with the view that research is the life of progress in agriculture, and that a point has been reached in our station work where it is imperatively necessary.

One session of the section on experiment station work was devoted to an open discussion upon The Kind and Character of Work under the Adams Act, and the Society for the Promotion of Agricultural Science, which met just prior to the convention, held a symposium on experimental work, which was occupied largely with this general subject.

In the latter, papers were presented by Prof. Thomas F. Hunt on What is Research?; by Dr. H. J. Wheeler on Tendencies in Station Work as Influenced by the Conception of Scientific Investigation, and by Director C. D. Woods on The Experiment Stations and the Adams Act. These papers were followed by a general discussion, and later by the presidential address of Dr. H. P. Armsby.

Doctor Armsby pointed to the popularity of the experiment stations as their greatest danger, since it "threatens to be their permanent undoing as agencies of scientific research." He urged the importance—nay, the necessity—of research as a basis for the development of agricultural education and of improved practice, and pointed out that the public needs to understand better than it does the nature and the importance of research. "Unless science makes progress, practice will mark time." Considering the provision for agricultural research which the Adams Act makes, he cautioned that this act may "prove also to be a day of judgment for the stations, in that it will reveal to all men their conception of original research and demonstrate whether or not they have a broad fundamental grasp of the idea of investigation. Differences of opinion regarding the application of this fund are already apparent. The stations stand at the parting of the ways. Will they simply add demonstration to demonstration, propaganda to propaganda, or will they grasp the opportunity to dedicate this new fund sacredly and irrevocably to original scientific research, broadly conceived and liberally executed?"

The discussion in the section on experiment station work served to reinforce the general opinion that the new fund should be used for investigation in a strict sense, and by illustration it helped to show the distinguishing characters of such work and to bring out the distinction between information, facts, and knowledge. Information may be of a very general nature, entirely empirical in character, and bear no relation to the cause or reason. Much that we publish as a result of our experiments is merely statistical information, with no attempt to trace the why or wherefore. A fact implies something more definitely established, but this may not be true of its relationships to other facts or observations. Isolated facts are often valuable when rightly applied, but it is when they are correlated into knowledge that they have their full value and contribute definitely to our understanding of principles.

As Doctor Armsby said in his excellent paper on Problems of Animal Nutrition, "one principle well founded is worth a thousand facts, because it includes them all;" and he added, referring to the subject under discussion, "I can not avoid suspecting that the principles which have been borrowed from foreign investigators and popularized by station literature and in other ways have done quite as much to help the practical feeder as our own experiments."

The principal doubt expressed in connection with the inauguration of research work was as to the attitude of the constituents of the station, and the ability to suppress their impatience for results. This difficulty is believed to be in a measure overestimated. While it is

true that the public does not like long-time investments and wants to see the results or the prospects of them, it is also true that it has made great strides in the appreciation of scientific investigation of agricultural problems, and has become more patient to wait until safe results can be secured. In some quarters it has already become impatient of inconclusive work. It can be interested in investigations into the why and wherefore as it could not have been a few years ago, and this tendency, it is believed, can be developed and intensified.

Education will do much to remedy this condition. It is not so many years since the only interest of the farmers in some sections was in substations and simple demonstrations. Now it goes much further. We should not yield to this apparent obstacle, although we recognize it and take account of it in the selection of our research problems. Many of these may be made to appeal to the farmer if they have a definite aim, and at least a considerable number of men can be made to see their importance, even though they be quite technical, and to support the station in the undertaking.

Take a specific case: Tomatoes grow luxuriantly in a certain State but tend to set fruit only sparingly. This is not a varietal characteristic, is not local, and does not appear to yield to the usual cultural methods. The cause for it is unknown. It may, it is thought, have some connection with the semiarid condition of the soil or atmosphere, the richness of the soil or its deficiency in some fertilizing element, or it may be due to other causes. It is a live, practical question. The station in that State might conduct a variety of field trials, working in the dark, in the endeavor to hit upon some method which would increase the tendency to set fruit: or it can, as is proposed, conduct a systematic investigation into the cause of this phenomenon, eliminating the effect of various factors one by one, and studying the problem in its physiological considerations as a basis for practical deductions.

The chances for ultimate practical results are greater in the latter case than in the former. Moreover, the work will be thoroughly done as each phase is taken up, and results of scientific interest will be secured which may quite likely have a bearing upon other crops. Is the matter of less interest to the practical man because it is carried out in this thorough scientific way and he can not understand each step? And is he more likely to become impatient at delay than if miscellaneous field trials were made without any reference to the fundamental cause? It hardly seems likely, if he is given to understand that the station is addressing itself to the practical problem to the best of its ability.

But there are other problems whose practical relations seem more remote to the general public, and which have to be taken by them on faith. In a considerable number of States such researches can not

be undertaken with the present public sentiment, and we must look to States where this sentiment is more advanced and where the demands on the station are less insistent. Some of these researches have become indispensable to further progress and are of interest to all the stations, although only a few can enter upon them. In some instances we lack both the men and the equipment to carry them on in more than one or two places at the outset, and where these men and facilities exist the great desirability of encouraging development to the fullest extent seems to need no argument.

This view was expressed by the section on experiment station work in reference to the investigations upon the principles of animal nutrition made with the aid of the respiration calorimeter at the Pennsylvania Station. The section commended this work in highest terms, recognizing its importance in the development of animal feeding; and in view of the special facilities combined at the Pennsylvania Station in investigator and apparatus, expressed "its earnest hope that at this time, when plans are being laid for so wide an extension of research in agriculture in the United States under the Adams Act, that the line of research already established by the Pennsylvania Station will be continued and developed to the fullest extent deemed practicable by the board of control."

The keynote of the discussion at the Baton Rouge meeting was that the provision for genuine research in agriculture had come none too soon, that our ideals should be set high, and that an enlightened public sentiment should be developed in the individual States as a foundation and support for it. In this advanced work public sentiment must be led. It can not be expected to lead the stations, as it often has in the case of the more practical work. The idea should be spread abroad that they can not solve fundamental problems at short order or get results of worth under high pressure. Given the proper aim, the stations must be allowed to work out the problems of agriculture in their own way.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY.

On methods of determining phosphoric acid in artificial fertilizers, P. CHRISTENSEN (*Tidsskr. Landökonom.*, 1906, No. 5, pp. 308-312).—This is a résumé of a monograph by the author on the subject.

The results of determinations of water-soluble phosphoric acid in the same superphosphates were found to differ as much as 0.75 per cent according to the modifications of the molybdate method proposed by Fresenius, Wagner, and Maereker. Similar differences were found in the results for citrate-soluble phosphoric acid in Thomas slag, and in the case of total phosphoric acid in bone meal differences of 1 per cent or more were obtained by the various methods. The differences were shown to depend on the manner of precipitating with magnesia mixture, and a method of procedure was worked out by the author which gave correct results. A rapid "direct molybdate" method is recommended for further trial. The yellow precipitate formed by addition of ammonium molybdate is ignited to constant weight, and the residue weighed for calculation of the per cent of phosphoric acid in the fertilizer. The methods are not described.

The author found that bone meal containing 31 per cent total phosphoric acid gave 30 per cent of phosphoric acid soluble in a 2 per cent citric-acid solution. Its citrate solubility was therefore equal to that of Thomas slag. It follows that phosphoric acid in bone meal must either be equal to that of Thomas slag or, if experience and exact culture trials show it to be less valuable, the present method of valuation of phosphoric acid in Thomas slag can not be considered reliable.—F. W. WOLL.

On the rapid analysis of superphosphates, M. JACQUET, G. QUINTANILLA, and F. ARREDONDO (*Rev. R. Acad. Cien. Madrid*, 4 (1906), No. 5, pp. 592-598).—The method proposed is as follows: Grind 2.5 gm. of the superphosphate in a mortar with about 15 cc. of cold distilled water, filtering the extract and repeating the operation until the filtrate amounts to about 200 cc., finally washing the filter with water at 80° C. After cooling add 1 or 2 cc. of nitric or hydrochloric acid to clear up the solution. Digest the filter and contents in 100 cc. of Joulie's citrate solution (400 gm. citric acid per liter) at 60° C. on a water bath for 3 hours, stirring for 1 or 2 minutes every quarter of an hour. Make the solution to 250 cc. To 50 cc. portions of the water and citrate solutions add 100 cc. of 22° ammonia and 10 to 15 cc. of magnesia mixture (55MgCl₂+105NH₄Cl+350NH₃ of 22°+H₂O to one liter). Shake in a mechanical agitator making 40 to 50 revolutions per minute for 3 hours, collect the precipitate on a filter, and proceed as usual. This method gave results with a variety of materials closely agreeing with those obtained by the ordinary method. Increasing the revolutions of the shaker to 70 to 80 per minute and reducing the time to 1 hour gave higher results than those yielded by the ordinary method.

Investigations on the causes of error in the application of the citro-

mechanical method in the determination of phosphoric acid in natural phosphates and phosphatic slag, H. PELLET (*Ann. Chim. Analyt.*, 11 (1906), No. 9, pp. 331, 332; *abs. in Chem. Centbl.*, 1906, 11, No. 16, p. 1284).—The author briefly discusses the investigations of Guerry and Toussaint (E. S. R., 18, p. 197) on this subject and describes the method which he employs to remove silicic acid from solution, namely, moistening with hydrochloric acid, evaporating to dryness, and taking up in hot hydrochloric acid. It is claimed that the removal of silica is not necessary in the molybdic method, and that a precipitate of phospho-ammonium molybdate of definite composition can always be obtained.

On the determination of phosphoric acid as magnesium pyrophosphate, B. SCHMITZ (*Ztschr. Analyt. Chem.*, 45 (1906), No. 8, pp. 512–522; *abs. in Chem. Centbl.*, 1906, 11, No. 10, p. 911).—The author precipitates the nearly neutralized (with HCl) ammonia solution of the molybdic precipitate with acid (HCl) magnesia mixture, finally making the solution alkaline with ammonia.

Should one titrate calcareous marl with sulphuric acid? SCHULZE (*Chem. Ztg.*, 30 (1906), No. 77, pp. 937, 938).—A series of comparative tests is reported which showed that the use of sulphuric acid gives uniformly lower results than hydrochloric acid, but the reason for this is not made clear.

The determination of organic matter in waters by means of potassium permanganate, A. GARCIA (*Ann. Chim. Analyt.*, 11 (1906), No. 9, p. 340).—The author finds that the ammonia already present or set free from salts or organic matter in water by alkaline permanganate is oxidized to nitrous or nitric acid, which increases the amount of permanganate required, and thus alkaline permanganate gives higher results for organic matter than acid permanganate.

The detection of humus substances in water, KLUT (*Pharm. Ztg.*, 51 (1906), pp. 777, 778; *abs. in Chem. Centbl.*, 1906, 11, No. 13, p. 1081).—It is stated that no typical reaction for this purpose exists. Various indirect tests for color, odor, reaction, etc., are described.

A new method for the quantitative estimation of pentosans, A. JOLLES (*Ztschr. Analyt. Chem.*, 45 (1906), No. 3–4, pp. 196–204).—Detailed directions are given for estimating furfural, and data are reported showing the accuracy of the method, which consists essentially in boiling the substance to be tested with hydrochloric acid, distilling with water vapor the furfural formed, neutralizing with sodium-hydroxid solution, adding bisulphate solution, and titrating with iodine.

On uniform methods of analysis of cane factory products, H. PELLET (*Internat. Sugar Jour.*, 8 (1906), No. 94, pp. 506–511).—Notes are given on the steps which have been taken toward securing unification of the methods for saccharine products in different countries. Analyses of cane molasses made by three methods are given to illustrate the differences arising from the use of different methods. Comments are made on the suggestions which have been offered for the unification of methods and a résumé of methods for the analysis of molasses is given.

An accurate commercial method for the analysis of sugar beets, D. L. DAVOLL (*Internat. Sugar Jour.*, 8 (1906), No. 94, pp. 512–516, fig. 1).—Objections to the method of hot-water digestion are overcome, according to the author, by substituting a beaker for the flask, and finally completing the mass to a certain weight, 209.2 gm., instead of volume. By this method, which is described, it is possible to make from 600 to 700 analyses in one day, instead of 125 by the usual method.

Report on the estimation of glucose by the volumetric method, A. WATT (*Internat. Sugar Jour.*, 8 (1906), No. 94, pp. 502–506).—In determining glucose

in beet sugar it is considered important to standardize the Fehling solution with a solution of pure sucrose and invert sugar in the proportions found in the sample. If a clarified solution is used it is also considered necessary to clarify the standardizing solution before titration. When these precautions are taken the volumetric method is believed to be capable of giving as accurate results as the gravimetric method.

The method of analysis of milk used in the government laboratory for samples referred under the sale of food and drugs acts, H. D. RICHMOND and E. H. MILLER (*Analyst*, 31 (1906), No. 367, pp. 317-335).—In the case of fresh milk the maceration method employed in the government laboratory is believed to give results which are accurate for fat, but slightly too high for solids-not-fat. The higher results for the solids-not-fat are attributed in part to the occurrence of sugar in the hydrated form and to the presence of aldehyde in the ether.

In 18 out of 19 analyses of samples of sour milk the authors report fair agreement of the figures for fat by the maceration method with those obtained by the Gottlieb method on the fresh samples. A considerable variation in the remaining sample was attributed to an unusual decomposition.

The main part of the paper deals with the corrections allowed for decomposition products in calculating the composition of the fresh milk when the sample examined has undergone fermentative changes. The method employed in the government laboratory makes corrections for alcohol, volatile acids, and ammonia, and is believed to give results within 0.2 per cent of the truth except in cases of high butyric fermentation or other abnormal decomposition. The authors believe that certain small additional corrections may be made with advantage and suggest allowance for lactic acid, butyric acid, and the aldehyde taken up from the ether used.

The work, on the whole, indicates that the government laboratory method is substantially accurate for the usual samples, but that special corrections ought to be applied in cases of unusual fermentations, two of which were found by the authors in an examination of the 19 samples.

The refractometric determination of milk fat, F. LÖWE (*Milchz. Zentbl.*, 2 (1906), No. 9, pp. 414-416).—Scales have been constructed for the Wolny and Abbe refractometers whereby the percentages of fat may be read directly.

A modification of the salt method, RUSCHE (*Molk. Ztg.*, 20 (1906), No. 38, pp. 1075-1077).—In preliminary experiments the author obtained good results by reducing the amount of salt required in the Gerber alkali method from 240 to 120 gm. per liter and increasing the amount of alcohol from 0.6 to 1 cc. This modification is believed to lessen the danger of saponifying the fat.

The determination of acidity in cream, HESSE-GÜSTROW (*Milchz. Zentbl.*, 2 (1906), No. 9, pp. 418, 419).—In determining acidity by the Thörner method, it is considered necessary to weigh 10 gm. of cream rather than to measure 10 cc. with a pipette.

On the determination of fat in cheese, M. WEIBULL (*Ztschr. Untersuch. Nahr. u. Genussmit.*, 11 (1906), No. 12, pp. 736-738).—Comparative tests of the extraction, hydrochloric acid, and Gottlieb methods were considered as showing the superiority of the last-mentioned method for this purpose.

Investigations on the determination of soluble and insoluble volatile fatty acids, J. DELAITE and J. LEGRAND (*Bul. Soc. Chim. Belg.*, 20 (1906), No. 7, pp. 230-235).—The Reichert-Meißl number was found to increase from 30.03 when saponification was completed in $\frac{1}{4}$ hour to 46.53 when the period of saponification was prolonged to from 5 to 6 hours. This increase is considered due to depolymerization. Saponification for $\frac{1}{2}$ hour is recommended.

Saponification with glycerin and soda was compared with the usual method of saponification with alcohol and potash. The figures with glycerin were regularly 3 to 4 lower, and this method is therefore considered unsatisfactory.

On the use of chromed hide powder in the determination of tannin, E. NIHOUL (*Bul. Soc. Chim. Belg.*, 20 (1906), No. 7, pp. 236-240).—Comparative tests of hide powders containing from 0.6 to 5 per cent of chromium oxid are reported. The author gives preference to the use of powders only feebly charged with chromium.

Examination of some Western Australian barks, E. A. MANN and R. E. COWLES (*Jour. Soc. Chem. Indus.*, 25 (1906), No. 17, pp. 831, 832).—Determinations were made of the percentages of tannin in the barks of a number of common trees in Western Australia with the following results: *Acacia decurrens*, 15.1 per cent; *Eucalyptus salmonophloia*, 16.9, 19.8, and 12.25 per cent; *E. loriphleba*, 10.6 per cent; *E. longicornis*, 8.73 per cent; *E. redunca*, 12.5 per cent; *E. occidentalis*, 34.57, 39.3, and 44.5 per cent; and *E. cornula* 10.1 per cent.

[**Chemical work for the agricultural department of Western Australia**], E. A. MANN (*West. Aust. Govt. Lab. Bul.* 3, pp. 25-31, pls. 4).—The separation and study of poisonous principles in various plants, including especially poison bush (*Gastrolobium calycinum* and *Orylobium parviflorum*), *Indigofera bori-perda*, and darnel or drake (*Lolium temulentum*), which have proven injurious to stock, are briefly reported, as well as comparisons of total and available phosphoric acid and potash in certain typical soils of Western Australia, analyses of various lime and guano deposits, analyses of soil from a white ant hill showing an increase of total and available fertilizing constituents over surrounding soil, and miscellaneous analyses.

Practical methods for identifying and estimating boric acid together with rules for detecting forbidden preservatives, J. PRESCHER (*Die praktischen Methoden der Bestimmung und des Nachweises der Borsäure, nebst Anweisung zur Untersuchung auf verbotene Konservierungsmittel*, Lübeck: Charles Coleman, 1906, pp. 56, illus.; *rev. in Österr. Chem. Ztg.*, 9 (1906), No. 17, p. 240).—The directions which are given correspond to the law regarding the examination of meat, passed in 1900.

Pure food, drug, and paint law, E. F. LADD (*North Dakota Sta. Spec. Bul.* 4, pp. 18).—The State pure-food law as amended and reenacted and the pure-drug law and the paint law are given.

Pure food, pure drug, formaldehyde, Paris green, and paint laws, E. F. LADD (*North Dakota Sta. Spec. Bul.* 3, pp. 22).—This gives the essential features of each law with rulings and interpretations for the guidance of interested parties.

METEOROLOGY—WATER.

Monthly Weather Review (*Mo. Weather Rev.*, 34 (1906), Nos. 5, pp. 201-253, figs. 13, charts 15; 6, pp. 255-305, figs. 24, charts 6).—In addition to the usual reports on forecasts, warnings, weather and crop conditions, meteorological tables and charts for the months of May and June, 1906, monthly review of the progress of climatology throughout the world, recent papers bearing on meteorology, recent additions to the Weather Bureau Library, etc., these numbers contain the following articles and notes:

No. 5.—Present Day Climates in Their Time Relation, by F. M. Ball (see p. 312); Relations Between Velocities of Progression of Lows and the Areas of Rising and Falling Pressure Accompanying Them (illus.), by S. Hanzlik; Glaisher's Factors and Ferrel's Psychrometric Formula (illus.), by C. F. Marvin; Improvements in Seismographs with Mechanical Registration (illus.),

by C. F. Marvin; Weather Bureau Men as Educators; Educational Notes; A Destructive Local Storm Near Paris, Ill., by E. O. Laughlin; The Kodaikānal Solar Physics Observatory (illus.), by H. H. Kimball; Hawaiian Mountain Records; The Photoelectric Properties of Selenium Cells (illus.), by K. E. Guthe; West Indian Chart; Phenological Study; Meteorological Work in China, by C. F. Tabman; Abnormal April Temperatures in New South Wales, by H. A. Hunt; Severe Hailstorm in the Gulf of Mexico, by R. G. Bindley; The Seiche and Its Mechanical Explanation; Meteorology in German Universities; Observations of "Shadow Bands" Without an Eclipse; Tornado in Australia; and Meteorological Institute of Saxony.

No. 6.—The Mount Rose Weather Observatory (illus.), by J. E. Church, jr.; Use of the Lantern in Teaching Meteorology, by J. P. Goode; Studies on the Thermodynamics of the Atmosphere—IV. Numerical Computations in the Vertical Ordinate, by F. H. Bigelow; The Waterspout Near Tarrytown, N. Y., July 16, 1904 (illus.), by M. L. Bacon; The Tornado of June 6, 1906, near La Crosse, Wis., by G. A. Oberholzer; Weighting Forecasts; The Tornado of April 12, 1906, at Stafford, Kans. (illus.), by W. E. Seright; The Structure of Hailstones (illus.), by D. S. Landis; Suggestions to Observers of Hailstones; Weather Bureau Men as Educators; Lantern Slides for Lectures; Meteorology in Australia; The Energy of a Storm, by T. D. Smith; and Aero Clubs and Meteorology.

Meteorology, P. BONAME (*Rap. An. Sta. Agron. Mauritius, 1905, pp. 1-10*).—Observations on atmospheric pressure, temperature, precipitation, humidity, and evaporation in Mauritius during 1905 are summarized.

A marked fall of barometer preceding tornadoes which passed over or near the island is recorded. The year was unusually wet, the mean annual humidity being 88.4, the rainfall 2,410.2 mm., 50 per cent higher than for the previous year. The number of rainy days was 326 and the annual evaporation 376.2 mm.

Meteorological observations for the year 1905 at the Ploti Agricultural Experiment Station, M. SVOLINSKY (*Ghodichnuñ Otchet Ploty, Sel'sk. Khoz. Opitn. Stantsii, II (1905), pp. 1-24, 121-124*).—As in previous years, observations are reported on atmospheric precipitation, snow cover, evaporation, humidity of the air, temperature of the air and soil, sunshine, solar radiation, atmospheric pressure, and winds, with some description of the self-registering apparatus used. The characteristic features of the season 1905 were a marked deficiency of rainfall, especially during the summer, high temperatures of the air and soil, and increased sunshine.

Some facts about the weather, W. MARRIOTT (*London: Edward Stanford, 1906, pp. 32; rev. in Nature [London], 74 (1906), No. 1917, p. 295*).—A popular discussion of the subject especially adapted to the British Isles.

Weather forecasting from synoptic charts, A. J. HENRY (*Jour. Franklin Inst., 162 (1906), No. 4, pp. 297-316, figs. 6*).—This method, based upon two well established facts, namely, (1) the general eastward drift of the atmosphere in temperate latitudes of the Northern Hemisphere, and (2) the close relation between the weather and the distribution of atmospheric pressure, is described and the gain in accuracy, length, and usefulness of weather forecasts is discussed.

The recently organized weather service for North Germany, R. BÖRNSTEIN (*Mitt. Deut. Landw. Gesell., 21 (1906), No. 31, pp. 313, 314*).—This service is briefly described.

Cannonading against hail, TABARD (*Ann. Soc. Agr. Sci. et Indus. Lyon, 1905, pp. 43-65, figs. 3*).—This article discusses quite fully the history and present status of hail protection in France by cannonading, describing and discuss-

ing the theory of various forms of ordnance for this purpose, particularly the different forms of acetylene cannon first introduced by Maggiore Graziani, of Italy. The advantages of this system are quite fully explained.

Studies of the annual precipitation of the Continent of Africa, G. FRAUNBERGER (*Mitt. Justus Perthes' Geogr. Anst.*, 52 (1905), No. 4, pp. 73-82, map 1).—The available data on this subject are compiled, and a colored map showing the geographical distribution of rainfall is given, with discussions of the general rainfall characteristics of the continent and of different typical districts as follows: Eastern Sahara, Guinea coast region and hinterland, Congo and Orange, east side of longitude 25° and British East Africa, Somaliland, Abyssinia, Egyptian Sudan, and Egypt.

Climatology of South Africa (*Quart. Jour. Roy. Met. Soc.* [London], 32 (1906), No. 139, pp. 239, 240).—This is an abstract of a paper by C. Stewart before the British Association at its Cape Town meeting, summarizing quite fully the climatological conditions of South Africa, based upon the observations of a considerable number of stations scattered over the region.

The chief factors controlling the climate are stated to be ocean currents and elevation. A remarkable feature is the great uniformity in mean annual temperature, this being about 62° throughout the region. "This is due to decrease of temperature with increase of elevation above sea-level, almost neutralizing the increase of temperature which would otherwise occur with increased intensity of solar radiation due to a nearer approach to the equator."

The temperature of the coastal regions varies with relation to the ocean currents. South Africa is divided into three rainfall areas " (1) winter rainfall area in the west, (2) constant rains (small area) in south, and (3) summer rains in the east." There was little evidence in support of the "south-east rain" theory, especially for the coastal areas. In the cape peninsula the largest amount of sunshine occurs in summer; in the plateau regions in winter.

Present day climates in their time relation, F. M. BALL (*Mo. Weather Rev.*, 34 (1906), No. 5, pp. 201-205).—A brief review of some of the more important facts regarding climatic changes with special reference to geological changes.

It is stated that while we must conclude from all the scientific data available that all climates remain invariable, "the most elementary knowledge of geology and related earth sciences is sufficient to prove that climates have changed many times in the geologic ages through which the earth has passed. All theories accounting for such changes lead irresistibly to the conclusion that climates to-day must be changing, although not in any measurable amount."

Cold waves and frost in the United States, E. B. GARRIOTT (*U. S. Dept. Agr., Weather Bur. Bul. P.*, pp. 22, charts 328).—"The paper notes briefly the general distribution of the colder areas of the Northern Hemisphere, refers to general conditions that are associated with cold waves, and presents a chronological account of historical cold periods in the United States. It then summarizes and classifies the more important cold waves and frosts that occurred from 1888 to 1902, inclusive, and presents 328 charts that exhibit the meteorological conditions that attended the principal cold waves of that period."

The thermal anomalies on the earth's surface, F. HOPFNER (*Mitt. Justus Perthes' Geogr. Anst.*, 52 (1906), No. 2, pp. 32-36, chart 1).—New normal monthly and annual isothermal lines for the different hemispheres similar to those of Dove^a are calculated and charted to show thermal anomalies and

^a Die Verteilung der Wärme auf der Oberfläche der Erde (Berlin, 1852).

their probable causes. The possible sources of error in such work are discussed.

Annual variations in the temperature of the earth's surface (*Mitt. Justus Perthes' Geogr. Anst.*, 52 (1906), No. 2, p. 37, fig. 1).—Isothermal lines based upon data given in Hopfner's article above referred to are charted. These show directly the dependence of temperature upon the distance from the poles and indirectly its dependence upon the distribution of land and water.

An apparent periodicity in the yield of wheat for Eastern England, 1885 to 1905, W. N. SHAW (*Proc. Roy. Soc. [London]*, Ser. A, 78 (1906), No. A521, pp. 69-76, fig. 1).—An account of a continuation of studies which have been briefly reported elsewhere (E. S. R., 16, p. 955).

As a general conclusion from these further studies confined to Eastern England it is stated that "a relation between the autumn rainfall and the wheat crop is sufficiently manifest, but evidently the fall of rain is subject to disturbances of an irregular character which have little counterpart in the curve of wheat values."

The law of sequence in the yield of wheat for Eastern England, 1885-1904, W. N. SHAW (*Met. Ztschr.*, 1906, [Hann-Band], pp. 208-216, figs. 2).—A discussion is here given of comparative observations already noted from another source (see above).

The results of 20 years' observations for Eastern England indicate a somewhat different relation of crop and rainfall from that indicated by the observations for the whole of England, being as follows: Wheat yield = 46 bu. - 2.2 times the preceding autumn rainfall, and this relation held quite closely for 13 of the 20 years. The other 7 years, however, were somewhat anomalous and the rainfall-yield relationship did not hold. A closer examination of data for these years indicated an 11 year periodic fluctuation of yield made up of component harmonic periodic fluctuations having a common nodal point in the interval 1895-96, in which there was a reversal of the yield curve. In a later publication (see note below) the author compares the actual yields of wheat during 21 years, 1885-1905, with that computed from component curves having the following amplitudes:

Period (years)	11	11	11	11	11	11
		2	3	4	5	6
Amplitude (bushels)	+2.9	-0.5	-1.8	+2.8	+1	+1

The calculated and actual results show a remarkably close agreement throughout the period. The relationships here indicated apparently furnish a means of predicting the yield of future years. The yield thus predicted for 1905 was 31.9 bu., while the actual returns showed 32 bu.

Report of the meteorological committee, Great Britain (*Rpt. Met. Com.* [Gt. Brit.], 1906, pp. 154, pls. 5, fig. 1; abs. in *Nature* [London], 74 (1906), No. 1923, p. 477).—This consists as usual of administrative reports regarding organization and operations (during the year ended March 31, 1906) in marine meteorology, forecasts and storm warnings, climatology, publication, and miscellaneous subjects, with appendixes relating to the supply of information to the public, lists of logs and other documents received during the year, distribution of instruments, reports on inspections of meteorological stations, list of persons and institutions from whom publications are received, list of persons and institutions to whom publications are sent, and financial statement.

Among the more important researches begun or completed during the year are "(1) the study of the trajectories of air in traveling storms, embodied in an official publication entitled 'The Life-history of Surface Air Currents;' (2) redetermination of the velocity equivalents of the Beaufort scale of wind

force: (3) connection between the yield of wheat in eastern England and the rainfall of the previous autumn (see p. 313), and (4) possible relationship between exceptional strength of the southeast trade wind at St. Helena and exceptional rainfall in England."

The percentage of complete or partial success of special harvest forecasts was 89; of the regular forecasts for the whole of the British Isles, 88. The number of storm-warning telegrams justified by subsequent gales or strong winds was 88.4 per cent.

The work of the chemical laboratory of the **Ploti Agricultural Experiment Station in 1905**, B. M. WELBEL (*Ghodičnuü Otchet Ploty, Selsk. Khoz. Opitn. Stantzii, 11 (1905), pp. 73-119, 128-135*).—Analyses of atmospheric precipitation and drainage waters from lysimeters and of crops and soils used in pot experiments, with reference especially to content of nitrogen in different forms, are reported as in previous years, with discussion of the distribution of the nitrogen compounds and the nitrogen balance in the soil. The results obtained were very similar to those of previous years. The pot experiments showed that forage plants exert an individual influence on the rate of nitrification, esparcet being superior in this respect to alfalfa.

The experiments with barnyard manure, which were continued during the year as in previous years, show that the effect of the manure does not extend beyond 3 years and is shown mainly in an increase in nitric nitrogen and assimilable phosphoric acid in the soil.

The value of pure water, G. C. WHIPPLE (*Engin. Rec., 54 (1906), Nos. 10, pp. 269-272, fig. 1; 11, pp. 303-305*).—The contents of this paper are briefly summarized in part as follows:

"(1) Pure water as compared with impure water has a real financial value to a community. (2) This value may be measured by determining what impure water costs the community. (3) There are three principal characteristics which affect the value of water to the general consumer—its sanitary quality, its attractiveness, and its hardness. (4) A formula is suggested for computing the effect of the sanitary quality of water on its financial value to a community; it is based on the typhoid fever death rate. (5) A formula is suggested for computing the effect of the general attractiveness of water on its value to consumers; it is based on the physical characteristics of turbidity, color, and odor. (6) A formula is suggested for computing the effect of the hardness of water on its value to the consumers; it is based on the use of soap in the household. (7) Considered from the financial aspect alone, and disregarding all humanitarian considerations, the filtration of a polluted water supply adds very greatly to the vital assets of a community; hence, as a mere business proposition, no city can afford to allow an impure water supply to be publicly distributed. (8) The advantages to a community of having a water supply not only safe, but also attractive in appearance, taste, and odor, are material from a financial aspect; the increased value of many waters because of the improvement in their esthetic qualities alone justifies the cost of filtration. (9) Water-softening at present does not receive the attention it deserves at the hands of municipal authorities; the economic advantages to be gained by removing the hardness of water are so great that, in many cases, the saving to the ordinary water consumers justifies the cost of softening water."

Quality of water in the Upper Ohio River basin and at Erie, Penn., S. J. LEWIS (*U. S. Geol. Survey, Water-Supply and Irrig. Paper No. 161, pp. 114, pls. 6, figs. 3*).—"This paper discusses the quality of water on the most important tributaries of the Ohio River in Pennsylvania, New York, West Virginia, and Maryland, and the nature of the water supply at Erie, Penn. The amount and

character of the pollution is described and the results of drinking contaminated water as shown by typhoid statistics are indicated."

Summary of the underground-water resources of Mississippi, A. F. CRIDER and L. C. JOHNSON (*U. S. Geol. Survey, Water-Supply and Irrig. Paper No. 159, pp. VI+86, pls. 6, figs. 11*).—This bulletin gives a detailed account of observations on the topography, general geology, and underground-water resources of the State, including under the latter head notes on wells in different counties of the State, deep well records, and sanitary aspect of wells. (See also E. S. R., 17, p. 640.)

"In the Gulf Coastal Plain, of which Mississippi is a part, conditions are favorable for reducing to a minimum the death rate caused by drinking impure and unwholesome water. A study of the geologic conditions of the State shows that there is a great thickness of unconsolidated sands interbedded with water-tight clays which dip slightly to the south and west and form large underground reservoirs for the accumulation of water. The State has a heavy annual rainfall, which enters the upturned edges of the open-textured sands, collects in these wide reservoirs, and thus becomes available as well water when the overlying strata are drilled through. Good deep-well water can be obtained over almost the entire State, and there are large areas in which under favorable conditions flowing wells are obtained. The dip of the strata is so regular and the water horizons are so numerous that the areas are small in which potable water can not be found at comparatively shallow depths.

"In most of the localities having flowing wells the supply seems adequate for all demands so far made upon it. The low cost of drilling wells in the Gulf embayment has made it possible for even the poorest to have plenty of good water. Railroads, cotton mills, sawmills, canning factories, and various public works have found the deep-well water cheaper and better than surficial water. Along the southern coast in the rice area water for irrigation is in many places obtained from artesian wells."

The advantages of driven, bored, or drilled wells over open wells are quite fully explained.

Underground water papers, M. L. FULLER (*U. S. Geol. Survey, Water-Supply and Irrig. Paper No. 160, pp. 104, pl. 1, figs. 4*).—A number of short papers by different authors dealing with questions relating to the occurrence, distribution, amount, contamination, peculiarities, and methods of study of underground waters.

Bibliographic review and index of underground-water literature published in the United States in 1905, M. L. FULLER, F. G. CLAPP, and B. L. JOHNSON (*U. S. Geol. Survey, Water-Supply and Irrig. Paper No. 163, pp. 139*).—A bibliography of 721 titles, with an alphabetical index of subjects, is given.

Destructive floods in the United States in 1905, E. C. MURPHY ET AL. (*U. S. Geol. Survey, Water-Supply and Irrig. Paper No. 162, pp. V+105, pls. 4, figs. 11*).—Data are given for 19 floods occurring in the United States during the year, with notes on damage caused in some cases and possible means of prevention or control. The bulletin also contains a discussion of flood discharge and frequency and an index to flood literature in the United States.

SOILS—FERTILIZERS.

Soils, E. W. HILGARD (*New York and London: The Macmillan Co., 1906, pp. XXVII+593, figs. 90*).—This volume embodies the matured fruits of a long and varied experience, generally under pioneer conditions, in both humid and arid regions. Its conclusions are of especial value because they are based to

so large an extent upon studies of soils in their natural condition and in which cultural adaptations have not been obscured by long years of artificial treatment. In the author's opinion the advance of knowledge of soils has been retarded by the fact that investigations in this field have dealt mainly with more or less artificial soils—that is, soils which have long been under cultivation and whose natural relations to vegetation have thus been obscured.

The book "includes the discussion both of the methods and results of direct physical, chemical, and botanical soil investigation, as well as the subject-matter relating to the origin, formation, classification, and physical as well as chemical nature of soil, usually included in works on scientific agriculture.

"In the presentation of these subjects, it has been the writer's aim to reach both the students in his own classes and in the agricultural colleges generally, as well as the fast increasing class of farmers of both regions who are willing and even anxious to avail themselves of the results and principles of scientific investigation, without 'shying off' from the new or unfamiliar words necessary to embody new ideas. . . . But in order to segregate to some extent the generally intelligible matter from that which requires more scientific preparation than can now be generally expected, it has been thought best to use in the text two kinds of type; the larger one embodying the matter presumed to be interesting and intelligible to the general reader, while the smaller type carries the illustrative detail and discussion which will be sought chiefly by the student.

"As regards the chemical nomenclature used in this volume, the writer has not thought it advisable to follow the example set by some late authors in substituting for the well-known names of the bases and acids, those of the elements, and still less, those of the intangible ions. . . .

"Inasmuch as all the elements are presented to and contained in the plant in compounds only, and these compounds are themselves, in the dilute solutions used by plants, known to be largely dissociated into their basic and acid groups, it seems to be most natural to present them under the corresponding, even if not absolutely theoretically correct names of acids and bases, to which the farmer and the trade have been accustomed for half a century. Upon these considerations the long-used designations of potash, soda, lime, phosphoric, sulphuric, nitric, and other acids and bases have been retained in this volume, adding the chemical formula where, as in analytical statements, a doubt as to their meaning might arise."

The make-up of the book is indicated by the following summary of its contents: An introduction and 5 chapters devoted to origin and formation of soils, 12 chapters to physics of soils, 6 chapters to chemistry of soils, and 3 chapters to soils and native vegetation.

The soil and its cultivation, P. DIEFLOTH (*Le sol et les labours*, Paris: J. B. Baillière & Son, 1906, pp. 490, figs. 144; rev. in *Mois Sci.*, 8 (1906), No. 4, p. 15; *Nature* [London], 74 (1906), No. 1905, p. 4).—This is one of the series of volumes constituting the *Encyclopédie agricole*, edited by G. Wéry.

The volume treats of the origin, properties, composition, analysis, and cultivation of soils, and is divided into two main parts, agronomy and preparation of the soil. Under the general head of agronomy are discussed the relation of land to agriculture and the general rules and principles which govern the relations between the nature of the soil and the products which it yields. The second part treats of the various operations of clearing, cultivating, and improving land. The soil is considered in its threefold relation of mechanical support, reserve material, and medium, and recent discoveries regarding the relation of the soil to the nutrition of plants are embodied in the work.

Methods of physical, mechanical, geological, and chemical analysis of soils are briefly described.

Soil survey field book (*U. S. Dept. Agr., Bur. Soils, Soil Survey Field Book, 1906, pp. 319, fig. 1*).—This is a revision of instructions to Field Parties and Description of Soil Types, published in 1904, in which an attempt has been made to correlate the soils of the United States in the light of the additional information which has been obtained from soil surveys since that time, only such changes being made as were considered necessary to bring each soil into its proper place in the classification.

The book contains directions for surveying soils; classification of soils according to type, class, and series; instructions for estimating and mapping alkali; methods of determining total salts in water; instructions for the qualitative determination of alkali salts; instructions regarding the collection of laboratory samples and the preparation of reports; descriptions of established soil types; indexes of soil types arranged alphabetically by crops and series and by States; and an alphabetical list giving number and page of soil survey reports in which the different descriptions of soils are found.

Alkali soils of the United States, C. W. DORSEY (*U. S. Dept. Agr., Bur. Soils Bul. 35, pp. 196, figs. 13*).—This is a review of literature and summary of present information, dealing with the alkali content of arid soils, comparison of soils of arid and humid regions, origin of alkali, kinds of alkali, accumulation of alkali in the soil, and resistance of plants to alkali, with a résumé of the work of agricultural experiment stations on alkali soils, and the soil and alkali surveys in the irrigated districts, laboratory investigations, and reclamation experiments by the Bureau of Soils.

Analyses of soils, C. F. JURITZ (*Rpt. Senior Anal. Cape Good Hope, 1905, pp. 31, 32*).—Percentage of fine earth passing $\frac{1}{2}$ -mm. mesh sieve and partial chemical analyses of soil passing 1-mm. and $\frac{1}{2}$ -mm. mesh sieves are reported (water, organic matter, chlorine, and nitrogen in the first case and lime, potash, and phosphoric acid in the second) for 47 samples of soil from different parts of the Cape of Good Hope.

On certain physical properties of sands and the method of their determination, E. J. KÖHLER (*Über einige physikalische Eigenschaften des Sandes und die Methoden zu deren Bestimmung. Nuremberg: V. E. Sebold, 1906, pp. 85, pl. 1, figs. 5*).—This thesis discusses and gives the results of studies of those properties of sand—size and shape of particles, porosity, relation to movement of water, etc.—which are of special importance to the engineer. The results, however, are also of importance from the standpoint of the physics of soil moisture.

A list of references to the literature of the subject is given.

Contributions to our knowledge of the composition of humus, E. J. MICHELET (*Arch. Math. og Naturvidensk., 27, No. 7, pp. 18*).—Ten samples of decayed wood, lake mud, or cultivated soils were examined for their contents of water, ash, organic substances, nitrogen, carbon, hydrogen, pentosans, methyl pentosans, methoxyl number, the object in view being to ascertain the variations in the pentosan contents of natural humus substances and the relation between the methyl pentosans and the pentosans, as well as to examine whether the presence of methyl groups combined with oxygen ($O-CH_3$) in the humus could be proved by the so-called methoxyl number.—F. W. WOLL.

The influence of long-continued rains on the impoverishment of soils, L. GRANDEAU (*Jour. Agr. Prat., n. ser., 11 (1906), No. 17, pp. 521, 522*).—This deals especially with the influence of long-continued rains in checking nitrifi-

cation and washing nitrates from the soil. The loss of potash and phosphoric acid from this cause is inconsiderable.

The erosion of soil, or washing away of our farms, S. W. WARFIELD (*Bien. Rpt. Tenn. Dept. Agr., 1903-4, pp. 115-120*).—A brief discussion of this subject, showing its great importance to the farmers in middle and east Tennessee.

Preservation and improvement of soils, R. GALLAGHER (*Bien. Rpt. Tenn. Dept. Agr., 1903-4, pp. 120-124*).—A brief general discussion of this subject, including a description of a system of cultivation and rotation which the author has found effective in restoring the humus content of the soil and bringing back "unproductive and unsightly fields from barrenness to the production of paying crops." The rotation proposed is peas (for hay), rye, peas, wheat, fallow with manure, corn, wheat, clover.

Soil moisture, G. BURNS (*Yearbook Khediv. Agr. Soc., Cairo, 1905, pp. 265-272*).—A general discussion of this subject with special reference to Egyptian conditions is given and experiments to test the effect of surface cultivation to conserve soil moisture are reported. Surface cultivation in general reduced the loss of water, but shallow cultivation (hoeing) proved better than deep cultivation during the hot summer months.

The moisture conditions of a loam soil under various crops, C. VON SEELHORST (*Jour. Landw., 54 (1906), No. 2, pp. 187-206, pls. 3; abs. in Chem. Ztg., 30 (1906), No. 62, Repert. No. 25, p. 255*).—Data for yields and moisture content of soils in case of field experiments during 3 years with potatoes, wheat, rye, oats, beets, peas, and clover are reported and discussed. It was observed that rye exhausted the soil moisture less than wheat. The exhaustion was especially marked in case of clover and oats and was very small in case of potatoes and peas. The application of the results in deciding upon the best rotation to conserve soil moisture is indicated.

Investigations of the hygroscopicity of some typical Swedish soils, G. NANNES (*K. Landtbr. Akad. Handl. och Tidskr., 44 (1905), No. 6, pp. 382-386*).—Determinations of the hygroscopicity of soils were made by drying 5 gm. of the air-dry sample for 5 to 6 days over 10 per cent sulphuric acid in a desiccator in partial vacuum at ordinary room temperature. The weight being constant after this period the residual water was determined in the humus soils according to Arntz's method by drying in a dry current of air at 105° C., and in the other kinds of soil, in a drying oven at the temperatures for the respective soil types given by Rodewald and Mitscherlich. The results of the investigations of soils in Skaraborg County, Sweden, made by the author indicate that the hygroscopicity per cent of sandy, sandy loam, and peat soils ought not to be less than half the amount of organic substance which they contain, while that of clay soils ought not to go appreciably below the content of organic substance, and should be higher, the more fertile the soil is.—F. W. WOLL.

Measurements of soil temperatures at Norwegian stations, 1903-4, G. HOLTSMARK and A. K. ANDERSEN (*Norges Landbr. Høiskoles Skr., 1905, No. 8, pp. 22*).—This is a continuation of previous observations, with average data for Aas station for 1896-1904, and for the stations at Jönsberg, Rotvold, Bodö, and Stend for the period 1900-1904. The following average annual figures will prove of interest. The latitude, longitude east of Greenwich, and altitude of the different stations are as follows: Jönsberg, 60° 45', 11° 12', 200 meters; Rotvold, 63° 26', 10° 29', 24 meters; Bodö, 67° 16', 14° 26', 15 meters; Stend, 60° 16', 5° 20', 48 meters.

Average annual soil temperatures for Norwegian stations.

Name of station.	Period.	Air temperature.	Temperature of soil at—			
			One-fourth meter.	One-half meter.	One meter.	One and one-half meters.
Aas	1896-1904	4.28	5.67	5.74	5.97	6.13
Jönsberg	1900-1904	1.54	3.38	4.06	4.37
Rotvold	1900-1904	4.33	4.59	4.97
Bodö	1900-1904	3.20	3.43	3.72	4.02
Stend	1900-1904	5.16	6.01	6.42	6.54

—F. W. WOLL.

The solvent action of roots upon the soil particles, A. D. HALL (*Sci. Prog. Twentieth Cent., 1 (1906), No. 1, pp. 51-57*).—The author reviews the literature of this subject, reaching the conclusion "that it is not necessary to assume the existence of an excretion from the roots of the plant of a permanent acid, organic or inorganic, to attack the solid mineral particles of the soil and to bring them into solution for the nutrition of the plant. The growing portions of a plant root are always giving off carbon dioxide, and carbon dioxide, especially in the concentrated solution which must be momentarily formed in the cell wall of the root hairs, has an appreciable solvent effect upon the majority of the minerals composing the soil. This carbon dioxide alone is capable of giving rise to such solutions as are required for the nutrition of the plant. As the direct evidence is also adverse to the idea of an excretion of acid, the principle of not seeking remote causes would lead us to attribute to carbon dioxide, and to carbon dioxide only, the long-recognized solvent power of the plant upon the soil."

The fallow in modern agriculture, S. RHODIN (*K. Landtbr. Akad. Handl. och Tidskr., 45 (1906), No. 1, pp. 57-72, fig. 1*).—The evidence and views in regard to the value of bare fallow, especially in Swedish agriculture, are briefly discussed. While bare fallow of loose sandy soils is not to be recommended, because the losses of nitrogenous substances occurring, generally speaking, exceed the gains through nitrification, this is not the case with other types of soils. Here an accumulation of nitrates takes place through the fallow, which greatly benefits the following grain crop.

Field experiments with cabbages in 1903 and with potatoes in 1904 and 1905 were conducted for the purpose of determining whether inoculation of sandy soils with fallow soil would prove beneficial on account of the large bacterial content of the latter. The systems of fertilization followed are shown below, the different plats receiving as a basal fertilizer 37 per cent potash salt and Thomas phosphate, at the rate of 225 and 400 lbs. per acre, respectively. The nitrate of soda was applied at the rate of 300 lbs. per hectare (267 lbs. per acre) and the inoculated soil at the rate of 6 cubic meters per hectare.

Yields per acre and percentage increase of crops on inoculated and uninoculated gravelly soil.

	Cabbages, 1903.		Potatoes, 1904.		Potatoes, 1905.	
	Pounds.	Per cent.	Pounds.	Per cent.	Pounds.	Per cent.
No fertilizer	8,906.88	36	6,791.49	39	9,908.90	62
Potassium phosphate	24,582.99	100	17,368.42	100	15,809.72	100
Potassium phosphate + soil from bean field	24,939.27	101	20,819.84	120	20,485.83	130
Potassium phosphate + soil from fallow field	33,222.67	135	23,046.56	132	18,370.44	116
Potassium phosphate + nitrate of soda	60,834.00	250	30,172.06	173	23,046.56	145

The author calls attention to the fact that a marked after-effect of the nitrate of soda is noticeable, even as late as two years from its application; there is an increase in the subsequent crops grown on the nitrate plats, as previously called attention to by Maereker, Wagner, and Weitz: the explanation given by Wagner is that the nitrate is changed by the calcium carbonate in the soil into sodium carbonate, which occludes the soil particles and increases the water-retaining power of the soil, and thereby also the subsequent crops grown on the land.—F. W. WOLL.

Recent contributions to our knowledge of moor land culture, H. VON FEILITZEN (*K. Landtbr. Akad. Handl. och Tidskr.*, 44 (1905), No. 6, pp. 369–381).—A general résumé of recent research work on moor soils.

Culture trials of the Swedish Moor Culture Society at Jönköping and Flahult, H. VON FEILITZEN (*Svenska Mosskulturför. Tidskr.*, 20 (1906), No. 3, pp. 193–219, figs. 2).—Among the trials described in this report the following may be mentioned: Trials with liming and applications of sand, white moss or peat soil (*dyjord*) on moor soils; fertilizer trials with 37 per cent potash salt and mineral fertilizer (ground feldspar); with different potash salts, phosphates, and nitrogenous fertilizers, with lime niter, nitrate of soda for pasture land and for winter rye on sanded white-moss soils.—F. W. WOLL.

Plant culture and fertilizer trials in Northern Norway (Tromsø Stift), B. R. LARSEN (*Tidsskr. Norske Landbr.*, 12 (1905), No. 9, pp. 389–398).—The article gives a brief account of trials with potatoes, turnips, and other root crops, and of a few fertilizer trials conducted in this northern region. In several subsequent issues of the *Tidsskrift* various phases of agriculture in this region are further discussed by different writers.—F. W. WOLL.

Results of vegetation experiments in the years 1901–1903, D. N. PRANISHNIKOV (*Izv. Moscov. Sel'sk. Khoz. Inst. (Ann. Inst. Agron. Moscou)*, 11 (1905), No. 2–3, pp. 155–219).—The present article is a report for the sixth, seventh, and eighth years of the culture experiments. The following are the general conclusions of the author:

(1) By the introduction of ammonium salts in sand cultures the conditions of the assimilation of phosphoric acid are essentially changed, even the difficultly soluble phosphates becoming available for all the plants. This influence may ordinarily be caused by nitrification, but it may also result from the physiological acidity of such salts as ammonium sulphate. It is obvious that in the nitrification of the latter two acids—nitric acid formed from the base and sulphuric acid—must be neutralized. Ammonium nitrate of all the sources of nitrogen appears to be most favorable for the maintaining of the nutrient solutions in the neutral state; but even this salt can not be used when the availability of the various phosphates is tested, since it may undergo nitrification and may also become physiologically active.

(2) Ash washed with water (to remove potassium carbonate) contains the phosphoric acid in a highly assimilable form; the development of plants provided only with this source of phosphoric acid is not only equal to that of "normal cultures," but frequently surpasses it; this once more proves that the so-called normal cultures elaborated by Knop, Hellriegel, and others do not have the ideal composition.

(3) As in previous experiments, phosphoric acid in the form of bone meal proved in sand cultures to be fairly available, the yields with bone meal being in most cases not lower than 60 per cent of those obtained with soluble phosphates. If, however, calcium carbonate or ferric hydrate were added the yields with bone meal were considerably lower.

(4) The sand cultures with phosphorites of different origin seem to warrant the conclusion that the variations in the solvent power of different plants

may be more important than the varying properties of the phosphates. Lupines, for example, can show, with an apatite like phosphorite, a considerable development not inferior to that with amorphous phosphorites, while the Gramineæ give with any phosphorite an extremely poor yield. In field cultures, however, the influence of the soil seems to predominate over everything else.

(5) Iron and aluminum phosphates are not to be considered as unavailable to the plants.

(6) As Votchal has also shown, potash mica proved in these experiments to be a considerably better source of potash than orthoclase.

(7) The data of the sand and water culture experiments regarding the importance of chlorin for plants do not corroborate the generally accepted opinion of the usefulness of chlorin as such for plant life. Of more importance, probably, is its influence on the physiological reaction of the culture media.

(8) The liming experiments lead to the following conclusion: While it is true that the optimum amount of lime introduced depends not only on the properties of the soil, but also on those of the plant, it seems to be beyond a doubt that the influence of the soil is much stronger than that of the plant: thus the lupine, which is considered a calcifugous plant, tolerated on a chernozem soil larger quantities of lime (1 per cent of the total weight of the soil) than oats on a marshy clay.—P. FIREMAN.

On the value of soil analyses for ascertaining the fertilizer requirements of soils, M. WEIBULL (*Malmö. Läns K. Hushall. Sällsk. Körtsskr.*, 1905, No. 3, pp. 592-597).—The article gives a brief summary of the author's views with regard to the practical value of soil analysis, based largely on the experience gained during several years' field experimentation on Swedish farms, in connection with chemical and mechanical analyses of the soils on which crops were grown. He concludes that determinations of the nitrogen and phosphoric-acid contents of a soil are of no practical value, since all normal soils respond to nitrogenous fertilization, irrespective of their nitrogen content, and no definite relation has been found between the phosphoric-acid content of the soil and the manner in which they respond to applications of this ingredient. As regards potash, three points should be kept in view, the potash content of the soil, its stiffness (content of clay), and the crop to be grown thereon. If a soil contains less than the following average percentages of potash soluble in warm hydrochloric acid (sp. gr. 1.1), it is nearly always benefited by potash fertilizers: Heavy, medium, and light clay soils, 0.25, 0.20, and 0.15 per cent, respectively; clayey sandy and sandy soils, 0.12 per cent. Potatoes, barley, and other crops which need considerable soluble potash call for potash fertilizers when grown on a soil containing as much as or less potash than given; on the other hand, oats under similar conditions will not require potash.

As regards lime, the reaction of the soil is important. Acid soils always require applications of lime, at least sufficient to change their reaction to neutral. Neutral soils as a rule only need lime when their content of assimilable lime is less than 0.25 per cent, or in the case of heavy clay soils, where an addition of quicklime or slaked lime will decrease their stiffness. Alkaline soils do not, generally speaking, need lime, but if very heavy may be improved physically by applications of burnt or slaked lime.—F. W. WOLL.

A contribution to practical soil analysis, M. WEIBULL (*Chem. Ztg.*, 30 (1906), No. 59, p. 722; *abs. in Chem. Centbl.*, 1906, II, No. 8, p. 703).—See abstract above.

The relation of sodium to potassium in soil and solution cultures, J. F. BREAZEALE (*Jour. Amer. Chem. Soc.*, 28 (1906), No. 8, pp. 1013-1025, pl. 1).—This subject was studied in a series of experiments with wheat and one ex-

periment with radishes by the pot and water-culture methods of the Bureau of Soils of this Department, the plants being grown for 15 to 19 days in solutions or 24 to 32 days in soils containing varying proportions of potash, soda, and other constituents, but of equal concentration, and then being transferred for 2 or 3 days' growth in a full nutrient solution. It was observed that the general development of the plants was in the same relative order as their transpiration. The presence of sodium increased the transpiration and size of plants even when there was an abundance of potash and other mineral constituents in the solution. As a rule, however, the effect of soda in increasing the size of the plant was not marked where no potash was present.

In case of both soil and solution cultures "there was a greater demand for potassium in the plants which had been growing in a [medium] which had received no potassium than in the plants which had always had a sufficient quantity of that element. . . . The absorption of potassium from the solution of the second period was strikingly decreased when sodium was present in the solution of the first period. . . . Plants which for the first period grew in a solution containing sodium but no potassium drew less heavily upon the potassium of the full nutrient solution than the plants which for the first period grew in a solution containing neither sodium nor potassium. There was a greater absorption of potassium where sodium had been absent than where it had been present."

The deficiency of potash resulting from systems of fertilization in Belgium, VERSTRAETE (*Bul. Soc. Chim. Belg.*, 19 (1905), No. 8-9, p. 267).—Figures are presented to show that the systems of fertilization practiced during many years past in Belgium have resulted in a decline in total and available potash.

The loss of nitrogen from soils in fertilizing with nitrate of soda, J. STOKLASA, J. JELÍNEK, and A. ERNEST (*Ztschr. Zuckerindus. Böhmen*, 30 (1906), No. 5, pp. 223-233; *abs. in Chem. Centbl.*, 1906, I, No. 14, pp. 1181, 1182; *Jour. Chem. Soc. [London]*, 96 (1906), No. 523, II, p. 303).—Culture tests in Gil-tay-Aberson solutions with various samples of soils rich in humus and of Bohemian sugar-beet soils are reported, which show that when glucose and salts of citric acid were present there was a considerable loss of nitrogen by denitrification. Other experiments with extracts of the soils inoculated with *Bacterium hartlebi* indicated that the soils were deficient in organic substances which could serve as a source of carbon for denitrifying organisms. The authors therefore conclude that with proper tillage these soils would not lose nitrogen in the free state.

The natural losses of nitrogen from soil and the use of nitrate of soda, L. GRANDEAU (*Jour. Agr. Prat., n. ser.*, 11 (1906), No. 18, pp. 553, 554).—A brief discussion of this subject based upon investigations made at Rothamsted (*E. S. R.*, 17, p. 533).

Nitrification as studied by means of drainage water, J. HUDIG (*Cultura*, 18 (1906), No. 211, pp. 149-163, fig. 1).—Studies by Sjollemma of the drainage water of 6 plats of land, each 300 square meters in area, during 4 years are reported.

The results show that the loss of nitrogen in the drainage water was very small and practically negligible. Even when nitrogen was applied in the spring in form of ammonium sulphate the losses were not large unless heavy rains occurred at the time. The nitrogen is apparently rapidly taken up by the young growing plants at this season of the year and only a small portion is free to pass into the drainage. The greatest losses occur in the fall, when the soil is bare and heavy rains occur, the nitrates having accumulated in large quantities during the warmer period of the year. Large losses at this season

are, however, prevented by the growing of cover crops. Observations on the same subject by Hall at Rothamsted are also reviewed.

The study of nitrification in soils by means of drainage water investigations (*Mitt. Deut. Landw. Gesell.*, 21 (1906), No. 18, pp. 195-203, figs. 2).—This article is based upon reviews of the Rothamsted work by Miller and Hall and Bieler (E. S. R., 8, p. 636; 17, p. 542), and of Sjollem's investigations in Holland by Hudig (see p. 322).

The rôle of organic matter in nitrification, A. MÜNTZ and E. LAINÉ (*Compt. Rend. Acad. Sci. [Paris]*, 142 (1906), No. 8, pp. 430-435; *abs. in Jour. Chem. Soc. [London]*, 90 (1906), No. 523, 11, p. 298).—In view of the fact that Winogradsky has shown that organic matter is not necessary to the growth of nitrifying micro-organisms and that there is a general opinion that the presence of organic matter is a disadvantage rather than advantage in the growth of such organisms, the authors undertook to determine the true relation of organic matter to nitrification. With this purpose in view they studied the rate of nitrification in neutral ammonium humate prepared from garden soil and in a solution of sulphate of ammonia containing an equal amount of nitrogen. They also studied the rate of nitrification in natural soils of different kinds, including garden soil, compost, silico-calcareous soil, clay soil, and calcareous clay soil in unsterilized condition, and in two of the soils, one rich and the other poor in humus, after sterilization and subsequent inoculation both with a soil poor in humus and with one rich in humus.

The general conclusions reached in these investigations were that humus even in large quantity does not interfere with nitrification, but, on the other hand, is favorable to it. An abundance of humus is not a necessary condition to nitrification, since soils poor in this constituent gradually develop intensive nitrification. The humus, however, appears to favor the multiplication of the nitrifying organisms, and a soil which contains a large amount of humus is more abundantly supplied with these organisms and more apt to enter into rapid nitrification. The idea that organic matter in the soil interferes with nitrification must therefore be abandoned.

Investigations on intensive nitrification, A. MÜNTZ and E. LAINÉ (*Compt. Rend. Acad. Sci. [Paris]*, 141 (1905), No. 22, pp. 861-867; *abs. in Jour. Chem. Soc. [London]*, 90 (1906), No. 520, 11, p. 114).—The possibility of so intensifying nitrification that it may be made a means of supplying nitrates in time of war when outside supplies might be cut off was studied and experiments are reported which indicate that by using solutions containing 7.5 gm. per liter of ammonium sulphate and coarse-grained animal black in layers 2 m. thick, it would be possible at a temperature of 30° C. to produce nitrate at the rate of 5,000,000 to 6,000,000 kg. per hectare per year. With a compost of well-rotted leaves, manure, and soil in a layer 50 cm. deep moistened with a solution of 1 part of ammonium sulphate per 1,000 of water nitrates were produced at a rate of 1,200,000 kg. per hectare annually. A practical difficulty in connection with the method is the very dilute solution of nitrate obtained, requiring a large amount of evaporation, and the dilute solution of ammonium sulphate which must be used. By following methods similar to those employed in the old niter beds the nitrates were concentrated to 27 to 33 gm. per kilogram of soil (2.7 to 3.3 per cent) or over 150 gm. per liter of soil solution. The possibility of further concentration of solutions obtained from oxidation by means of animal black by replacing the ammonium sulphate nitrified and passing the mixture of nitrates and ammonium salts through the beds again is being studied.

Niter and the national defense, A. MÜNTZ (*Ann. Inst. Nat. Agron.*, 2, ser.,

4 (1905), No. 2, pp. 219-226).—A discussion of the importance of developing methods of artificial preparation of nitrate of soda, especially by means of intensive nitrification, to replace supplies derived from natural nitrate deposits which are becoming exhausted or might be entirely cut off in time of war.

On a nitrogen assimilating Clostridium, H. PRINGSHEIM (*Centbl. Bakt. [etc.]*, 2. Abt., 16 (1906), No. 25, pp. 795-800; *abs. in Chem. Ztg.*, 30 (1906), No. 81, *Repert. No.* 35, p. 330).—The nitrogen assimilating capacity of a new species of Clostridium isolated by the author and named *Clostridium americanum* is compared with that of *C. pasteurianum* of Winogradski. It is shown among other things that the new Clostridium is much slower in its action than *C. pasteurianum*.

The bacteria of the root tubercles of leguminous plants, K. F. KELLERMANN and T. D. BECKWITH (*Centbl. Bakt. [etc.]*, 2. Abt., 16 (1906), No. 17-19, p. 540).—The behavior of the micro-organisms of the root tubercles of velvet beans, soy beans, garden peas, and alfalfa on various culture media is briefly described.

The securing of a supply of nitrogen for agriculture in the twentieth century, A. STUTZER (*Deut. Landw. Presse*, 33 (1906), No. 55, pp. 452, 453, figs. 4).—This is a brief discussion of means of utilizing the nitrogen of the air by means of leguminous plants and electrical processes. The utilization at Notodden, Norway, of cheap water power for production of the electrical energy used in oxidation of the nitrogen of the air is especially referred to.

The apparatus devised for utilizing the nitrogen of the air, A. NEUBURGER (*Ztschr. Angew. Chem.*, 19 (1906), No. 22, pp. 977-985, figs. 17).—The principles of construction and operation of the various forms of apparatus proposed for this purpose are briefly discussed.

The new Norwegian saltpeter industry (*Ugeskr. Landm.*, 1905, No. 52; *Hedcselsk. Tidsskr.*, 1906, No. 2, pp. 20-24).—The manufacture of nitrates by electrical processes at Notodden, Norway, is referred to.

The occurrence of sodium salts in Egypt with special reference to nitrate of soda, F. HUGHES (*Yearbook Khediv. Agr. Soc., Cairo*, 1905, pp. 145-170, fig. 1).—Lake and desert deposits are briefly referred to and the occurrence of sodium salts, especially nitrates, in the soils and drainage waters and in the natural manures known as koufri, marog, and tafila, is more fully discussed.

The salts most frequently found in soils are chlorid, sulphate, carbonate, and bicarbonate of sodium, the last two being much less abundant than the first two.

The occurrence of a large alluvial plain at Kom Ombo in Upper Egypt, which is impregnated with sodium chlorid, sulphate, and nitrate, is described, the nitrate occurring in sufficient amount to make the soil, which is known under the local name of marog, of value for fertilizing purposes. Analyses are reported which show as high as 5.9 per cent of nitrate in this soil. The salts are derived from clay hills immediately surrounding the plain.

Koufri, the most important natural manure of Lower Egypt, consists of the remains of old villages, which analysis shows to contain in some cases as high as 4.4 per cent of nitrate of soda besides various other salts.

The Esna shales (known as tafila) of Upper Egypt, containing from 6 to 8 per cent of nitrate of soda, are said to be the most important salt deposits in the country. A series of experiments in the extraction of this material, which gave a product containing 54 per cent of nitrate, is reported, and the economy of the process with limited water and fuel supply is discussed. The origin of the tafila salts is considered and the conclusion is reached that the nitrate which they contain has been produced by the decomposition of organic matter.

A bibliography of 25 references is given.

The manufacture of ammonium sulphate in Belgium (*Rev. Gén. Agron., n. ser., 1 (1906), No. 3, pp. 128, 129*).—This is a review of a report published by the minister of public works of Belgium, discussing especially the method of preparing ammonium sulphate by saturation of gas liquors with sulphuric acid. The annual production of Belgium is stated to be about 14,700 tons, 4,000 tons coming from gas works and 10,700 tons from furnaces.

Crude ammonia, L. BERGERON (*Jour. Agr. Prat., n. ser., 12 (1906), No. 32, pp. 177-179, fig. 1*).—The composition and use as fertilizer, weed destroyer, and insecticide of this by-product of gas making are briefly discussed. The composition of the material varies within the following wide limits: Water 10 to 25 per cent, ferrocyanid 5 to 15, free ammonia 0 to 2, ammonium sulphate 0.5 to 5, sulphocyanogen 0.5 to 7, ammonium cyanid 0.5 to 1, free sulphur 20 to 45. It is estimated that towns using gas produce about 1 ton of this material annually per 1,000 inhabitants. It is claimed that the material may be used with advantage as a fertilizer if applied from $1\frac{1}{2}$ to 2 months before seeding. Applied at the rate of 30 gm. per square foot the material has been found to be a very effective weed destroyer. It has also been found to be quite useful in combating nematodes, phylloxera, and other parasites. (See also E. S. R., 17, pp. 951, 1142.)

Six years' field experiments with nitrogenous fertilizers at Parc des Princes, L. GRANDEAU (*Jour. Agr. Prat., n. ser., 11 (1906), No. 23-24, pp. 702, 703*).—Field experiments on potatoes and corn fodder with different forms of nitrogenous fertilizers combined with various other fertilizing materials are briefly summarized, the results indicating that in general on a dry sandy soil poor in lime the action of nitric nitrogen is decidedly superior to that of ammoniacal or organic nitrogen.

Investigations on the changes which occur in the fermentation of manure, B. SJOLLEMA and J. C. DE RIJSTER DE WILDT (*Cultura, 18 (1906), Nos. 210, pp. 66-89, figs. 2; 211, pp. 130-141, fig. 1*).—The apparatus and methods used and the results obtained in studies of aerobic and anaerobic fermentation of manure at different temperatures are discussed and pot tests of fresh manure and that fermented under different conditions, in comparison with other fertilizers, are reported.

The investigations show that under certain conditions there may be a large loss of free nitrogen from fermenting manure, the extent of the loss depending largely upon the air supply. If the supply of air is cut off the loss of nitrogen in this form ceases. If air is freely admitted and the temperature maintained at about 50° C. ammonia is rapidly formed, but no free nitrogen is evolved. Excluding air, however, does not entirely prevent the formation of ammonia. Temperature appears to be a very important factor in determining the character of changes which occur. By fermentation at a low temperature with a deficient air supply, nitrogen compounds are formed which are not readily available to plants. The readily available albuminoid nitrogen of manure is assimilated by plants during the first year, and in case of some kinds of manure more than one-third of the nitrogen is taken up by plant roots within a few months. The ammonia content is not an exact measure of the effectiveness of the nitrogen in stable manure.

Experiments with lime as a preservative of manure, M. WEIBULL (*K. Landtbr. Akad. Handl. och Tidskr., 45 (1906), No. 1, pp. 3-15; abs. in Chem. Ztg., 30 (1906), No. 62, Repert. No. 25, p. 254*).—Experiments were made by the author during the years 1903-4 to study the preserving effect of lime on barnyard manure, and during the seasons 1903-1905 to study the fertilizer value of common and limed manure for wheat, potatoes, mustard, and fodder beets.

The average losses of the manure in weight, organic matter, total nitrogen, and ammonia during 3 to 3½ months were as follows: For common manure, loss in weight 25.9 per cent, organic matter 26.3, total nitrogen 16.5, and ammonia 40.7. For the limed manure (the lime being applied at the rate of 1.2 kg. per head daily): Loss in weight 22.3 per cent, organic matter 22.2, total nitrogen 16.9, and ammonia 41.6. The results of the field trials showed that, in the case of all the crops experimented with, the limed and the common manure possessed a similar fertilizer effect, thus indicating that these crops are able to appropriate similar amounts of nitrogen from both kinds of manure when this is well cared for and handled in a similar way.—F. W. WOLL.

Does didymium chlorid, a new disinfectant and preservative material, injuriously affect plant growth? O. BÜTTCHER (*Deut. Landw. Presse*, 32 (1905), No. 90, pp. 752, 753; *abs. in Centbl. Agr. Chem.*, 35 (1906), No. 7, pp. 451, 452).—Experiments are reported which indicate that this material, which is now being put on the market in Germany at prices which permit of its use as a disinfectant and preservative, is an effective preservative of manure and, in amounts necessary for this purpose, has no injurious effect upon plants.

The relation between the care of liquid manure and its content of valuable fertilizing constituents, A. STUTZER and P. VAGELER (*Fühling's Landw. Ztg.*, 55 (1906), No. 10, pp. 338-348).—Analyses of a large number of samples of liquid manure produced under a variety of conditions of care and management are reported, showing wide variations in composition with different methods of preparation and handling.

Phosphates in New Zealand, B. C. ASTON (*New Zeal. Dept. Agr., Chem. Div. Bul.* 1, pp. 10, pls. 4, figs. 4).—The deposits of phosphate which have already been discovered and exploited in New Zealand are briefly described and the terms of a bonus offered to encourage further discovery of phosphates in the island are explained. One of the most important recent discoveries of phosphates is that occurring in limestone pockets near Clarendon, Otago.

"New Zealand mineral phosphate, which has hitherto been found in workable quantities only at Milburn and Clarendon, Otago, has a dirty yellowish-white or light-gray color. Some specimens exhibit a decided pink tinge in patches. It is usually amorphous (non-crystalline), but thin veins of crystalline apatite have been found at Clarendon. . . . Since the discovery of phosphate at Clarendon some 15,000 tons of the fertilizer have been quarried, ground, and put on the market."

Phosphates in Nantes, L. GOLDSCHMIDT (*Daily Consular and Trade Rpts.* [U. S.], 1906, No. 2636, pp. 5, 6).—In connection with statistics of importation of phosphates into Nantes attention is called to the fact that formerly phosphates of high grade were imported into this city from Mona Island on the east coast of Porto Rico, and while the exploitation of these deposits ceased after a relatively short period it is believed that they may be worked with advantage.

The action of difficultly soluble phosphates on rye by means of lupines, A. MAYER (*Deut. Landw. Presse*, 33 (1906), No. 52, pp. 433, 434).—Field experiments are reported which show that insoluble phosphates applied to a previous crop of lupines gave better results at less cost in case of the following crop of rye than superphosphate.

The selection and use of fertilizers, W. P. BROOKS (*Farming*, 2 (1906), No. 2, pp. 50, 51).—This article is based on the "better farming" talks delivered on the special trains recently run through New England, and outlines briefly the principles which should guide in the purchase and use of fertilizers. It advocates the purchase of high-grade fertilizers especially adapted to the soil

and crop conditions in each case. The growth of beets on limed and unlimed plats is recommended as a good practical means of determining whether the soil is acid. The more generally useful results of fertilizer experiments on various crops at the Massachusetts Station are briefly summarized.

Food for plants (*New York: William S. Myers, 1905, rev. ed., pp. 241, figs. 42*).—This is a new edition, with supplementary notes, of this compilation prepared mainly from the writings of Joseph Harris and from the work of the various agricultural experiment stations. Notes and tables giving miscellaneous information are included.

Commercial fertilizers, G. ROBERTS (*California Sta. Bul. 179, pp. 57-83*).—This bulletin gives the results of fertilizer inspection for the second half of the fiscal year 1905-6, the results of the first half year having been published in Bulletin 173 of the station (E. S. R., 17, p. 1051). It reports examination of 239 samples of fertilizing materials, of which "22 were sent by farmers under the two-dollar fee provision, 56 were taken by inspectors from purchasers' goods upon the request of the purchasers, and 161 were taken by inspectors from goods in the hands of agents and manufacturers." The valuation of fertilizers is briefly discussed and suggestions are made regarding the purchase of fertilizers.

Analysis of commercial fertilizers sold in Maryland, H. B. McDONNELL ET AL. (*Md. Agr. Col. Quart., 1906, No. 33, pp. 56*).—Tables are given which show the guaranteed and actual composition and comparative value per ton of fertilizers inspected by the State chemist from February to July, 1906, inclusive.

Analyses of commercial fertilizers, W. FREAR (*Penn. Dept. Agr. Bul. 142, pp. 61*).—This bulletin gives the results of fertilizer inspection in Pennsylvania during the 5 months ended December 31, 1905.

A review of progress in the fertilizer industry for the year 1905 (*Ztschr. Angew. Chem., 19 (1906), No. 32, pp. 1390-1392*).—This is a brief review of progress made, especially in Germany, during the year in enlargement of plants and in development and improvement of milling and mixing machinery, methods and processes, and products. Considerable progress was made during the year in the enlargement of factories with their own sulphuric-acid plants, but the business was handicapped by a scarcity of labor and the profits were not large.

The fertilizer season records, W. L. SUMMERS (*Jour. Dept. Agr. So. Aust., 10 (1906), No. 1, p. 18*).—Statistics are given of the fertilizer trade in South Australia for the period 1897-1906. It is shown that the use of fertilizers has increased from 3,000 tons on 60,000 acres in 1897 to 59,000 tons on 1,321,600 acres in 1906. Of the fertilizers now used it is estimated that 95 per cent consist of superphosphates in some form or other.

Consumption of fertilizers, season of 1905-6 (*Amer. Fert., 25 (1906), No. 2, pp. 12, 13*).—Statistics are given for Mississippi, North Carolina, West Virginia, Kentucky, Florida, Missouri, Alabama, Tennessee, Texas, and California.

Sludge treatment in relation to sewage disposal, J. D. WATSON (*Engin. Rec., 54 (1906), No. 9, pp. 225, 246-249*).—The author reports experiments at Birmingham, England, in which exceedingly satisfactory results were obtained with the septic tank treatment for separating suspended matter from sewage, the sludge being disposed of on land. It is claimed that with the plant used the sewage of 900,000 people is disposed of without any objectionable odors at a cost of about 5 cts. per cubic yard of wet sludge.

The sewage is allowed to flow through a series of septic tanks at an average lineal velocity of about 1.2 ft. per minute; "the street wash and other coarse detritus are deposited in the first compartment of the septic tanks and removed about once a week; a large portion of what might be termed 'grit chamber

deposit' is pumped forward into the septic tanks; the deposit in the septic tanks is reduced to an inodorous humus mass by bacterial activity; and at intervals of about seven weeks or so the inodorous septic sludge is pumped upon adjoining lands, covering the same to a depth of some 8 to 10 in. . . . By absorption and evaporation the loss of water causes this sludge to be reduced to somewhat less than half its original bulk, and there results a fairly dry mass which thus far has been of little service for purpose of cultivation."

Rye gave unsatisfactory results on soil treated with sludge in the manner described. Italian rye grass gave better results. In black soil mixed with an equal amount of the sludge about one-third of various garden seeds germinated, but did not mature. "It was therefore quite clear that it was a mistake to run so much sludge on the surface of the land at one time, and in subsequent working not more than half the amount of sludge has been put on the surface of the ground, with far more satisfactory results."

AGRICULTURAL BOTANY.

Flora of the State of Washington, C. V. PIPER (*U. S. Nat. Mus., Contrib. Nat. Herbarium, 11, pp. 637, pls. 22, map 1*).—An account is given of the flora of the State of Washington, based upon the author's study of the plants of that State during a period of 20 years.

The principal aim in the work is to present a summary of our present knowledge of the vascular plants of Washington and to call attention to some of the more important taxonomic and ecological problems which are disclosed. The author describes the early botanical explorations of Washington, and gives an account of the physiography, geology, and climate of the State, after which he discusses the distribution of plants and gives an account of regions of peculiar botanical interest. Following this an annotated catalogue of the species of vascular plants of Washington is given, and an extended bibliography and index completes the publication.

Absorption of atmospheric moisture by desert shrubs, V. M. SPALDING (*Bul. Torrey Bot. Club, 33 (1906), No. 7, pp. 367-375*).—The author has been led to investigate the subject of the absorption of water directly from the atmosphere by leaves and other aerial parts of plants, and in the present paper gives a summary of his investigations.

It is found that of 12 species of desert perennials subjected to experiment all exhibited some slight capacity for direct absorption of water from the atmosphere, but in general the amount absorbed is very insignificant in comparison with that given off in corresponding periods in dry air. So far as the observations go, there appears to be no evidence that the quantities of water so absorbed are utilized in the body of the plant. The rapidity with which the water thus absorbed is returned to the atmosphere suggests that the process is a physical one and of no physiological significance.

This investigation seems to show that the roots of desert plants constitute their only reliable active agent in providing a normal water supply.

The relation of desert plants to soil moisture and to evaporation, B. E. LIVINGSTON (*Carnegie Inst. Washington Pub. 50, pp. 78, figs. 16*).—Studies were carried on at the desert laboratory of the Carnegie Institution, which is located near Tucson, Ariz., with reference to the relation between certain desert plants and their physical environment. The studies recorded are the results of an attempt to determine some facts in regard to the minimum water supply with which desert plants can thrive.

After discussing the relation of the soil and atmosphere the author takes

up the study of the plant. The main physical factor which was found to determine the nature of the vegetation on Tumamoc Hill near the laboratory was the water relation. Except during the rainy seasons, the soil on this hill is far too dry for most plants, and only those forms can live there that are adapted to dry soils and a high rate of evaporation.

Studies of the minimum water supply for germination of seeds were also made. With desert plants such as *Fouquieria splendens* and the giant cactus germination took place in soils containing from 15 to 20 per cent of moisture. For purposes of comparison a number of seeds of cultivated plants were investigated in the same way, and it was found that Mexican beans and wheat germinated in 15 per cent, but more vigorously in 20 per cent moisture in the soil; the cultivated balsam germinated slightly in 20 per cent, but much better in 25 per cent; radishes failed to germinate in soil containing less than 20 per cent moisture, and red clover did not germinate until a moisture content of at least 25 per cent had been reached.

In summarizing his conclusions, the author states that the deeper soil layers of Tumamoc Hill contain at the end of the dry season a water content adequate to the needs of those desert plants which are active during the months of drought. The soil moisture is conserved very largely by the high rate of evaporation and the consequent formation of a dust mulch.

Desert plants show an adaptation to existence in dry soil, being able to exist in soils somewhat drier than those needed by plants of humid regions, but this adaptation is comparatively slight and is not considered of primary importance. The downward penetration of precipitation water is slow in the soil itself, but comparatively rapid on the whole on account of the presence of numerous oblique rock surfaces along which the flow is not markedly impeded. By the middle of the summer rainy season all of the soil except the first few centimeters is sufficiently moist to allow the germination and growth of most plants. The seeds of *Fouquieria splendens* and *Cereus giganteus* failed to show any special adaptation to germination in soils drier than those needed by such seeds as beans and wheat.

Immediately following germination the seedlings of desert plants exhibit a slow aerial growth, but an exceedingly rapid elongation of the primary roots, so that these should soon attain to depths where moisture is always present in an amount adequate for growth. The high moisture-retaining power of the soil where these investigations were carried on holds near the surface much of the water received from single showers and offers excellent opportunity for the rapid absorption of this by shallow-growing plants, such as the cacti.

In the conduct of these experiments the author found that the effect of air currents in increasing evaporation and transpiration is so great that measurements of natural transpiration can not be made in closed chambers, and by means of a specially devised apparatus a physiological regulation of the rate of transpiration was shown to exist in the forms studied. The regulation of transpiration seems to be controlled by air temperature, the checking of water loss beginning to be effective between 79° and 90° F., and disappearing between 75° and 80° F.

A study of the variations in the nitrogen and phosphoric acid in the juices of succulent plants, G. ANDRÉ (*Compt. Rend. Acad. Sci. [Paris], 142 (1906), No. 15, pp. 902-904*).—A study of the variation in these constituents in *Mesembrianthemum crystallinum* at different stages of growth showed that the soluble phosphoric acid and nitrogen reached their maxima at the same periods of growth. The content of nitric acid in the juice was always comparatively large.

Cyanogenesis in plants, IV-V, W. R. DUNSTAN, T. A. HENRY, and S. J. M. AULD (*Proc. Roy. Soc. [London], Ser. B*, 78 (1906), No. B523, pp. 145-158).—The authors are making a systematic investigation of various plants with a view to ascertaining definitely whether they contain phaseolunatin. They have already reported upon the presence of this glucoside in *Phaseolus lunatus* (E. S. R., 15, p. 556), and in the present papers they deal with investigations with flax and cassava plants.

Previous investigators have reported the presence of a glucoside, linamarin, in flax, and the authors' studies have been carried on to determine its possible identity with phaseolunatin. In the isolation of the glucoside it is found that the flax plant differs from *Lotus arabicus* and *Sorghum vulgare*, which show a steadily increasing amount of glucoside until the plant approaches maturity, after which it decreases until there is none present in the seed. In the flax the seed contains a small amount of glucoside, which increases on germination, and reaches a maximum when the plants have attained a height of 2 or 3 in., after which it gradually diminishes and finally disappears. The authors isolated the glucoside from flax plants about 4 or 5 in. in height in which stems, leaves, and roots were used. The material obtained was compared with phaseolunatin, and the two substances proved to be identical. A study of the enzym of the flax showed that it would hydrolyze phaseolunatin from the seeds of *Phaseolus lunatus* and vice versa, so it seems probable that the enzym in both plants is identical.

In the second paper a report is given on the occurrence of phaseolunatin in cassava plants, the studies being made largely of the rind of the bitter root, which was specially prepared for the investigation. From this material a glucoside was separated which does not differ in any way from that obtained from the other plants mentioned above, and the enzym is closely related to, if not identical with, the emulsin-like ferment obtained from the seeds of *P. lunatus* and from young flax plants. It appears from the investigations that these plants, representing three widely separated orders, contain the same glucoside.

Additional species of rosaceous plants containing hydrocyanic acid, L. GUIGNARD (*Compt. Rend. Acad. Sci. [Paris]*, 143 (1906), No. 14, pp. 451-458).—Hitherto most of the species of rosaceous plants that have been reported to contain hydrocyanic acid in their foliage have belonged to the tribe *Prunae*. The author made extended investigations and found that a considerable number of species belonging to other tribes also contain hydrocyanic acid in their leaves. The amounts present vary from a mere trace to as great a content as that reported for the cherry laurel. The number of species known to contain hydrocyanic acid is about double that previously reported.

The latent vitality of seeds, P. BECQUEREL (*Compt. Rend. Acad. Sci. [Paris]*, 142 (1906), No. 26, pp. 1549-1551).—The author reports investigations on 550 species of seed, representing 30 of the more important families of plants, the seeds having been kept in storage from 25 to 135 years.

In the experiments at least 10 seeds were selected, carefully washed in sterilized water, and partially decorticated so as to make the integuments permeable. They were then placed on aseptic cotton under glass covers and kept at a uniform temperature of 28°. The results of the investigations are given in detail. Eighteen out of 90 leguminous species germinated, as well as 3 species of Nelumbium seed, 1 species of Malvaceæ, and 1 of Labiate. These seeds ranged in age from the season of 1819 to 1878, and in the case of one species of Nelumbium to 1888. No seed germinated belonging to any of the Gramineæ, Liliaceæ, Urticeæ, Polygonaceæ, Chenopodiaceæ, Ranunculaceæ, Eu-

phorbiaceae, Cruciferae, Papaveraceae, Rosaceae, Solanaceae, Boraginaceae, Convolvulaceae, Verbenaceae, Plantaginaceae, or Cucurbitaceae.

Among species of seed ranging from 30 to 60 years old, the author failed to get any germination of a number that have been frequently reported by other observers as having germinated after long periods of time. The oldest seed, which had retained its vitality for 80 years, included 3 species of leguminous seed protected by very thick integuments. In such seeds the seed coats seemed, through their impermeability, to have brought about a thorough drying of the seed such as is artificially produced by drying over chemicals or in vacuum, and in this way the reserve material was protected from oxidation.

FIELD CROPS.

Crop rotation, J. S. COLE (*South Dakota Sta. Bul. 98, pp. 75-103*).—The experiment here reported has been in progress since 1897. Earlier results have been previously noted (E. S. R., 15, p. 237), and a revised outline is here given. The purpose of the present bulletin is to show which crops reduce soil fertility and which maintain its productivity. The best order of succession of crops is also shown as indicated by these results.

The best average yields of wheat were secured after either corn or potatoes. Results following these two in order of merit were obtained from summer fallow, millet, vetch, peas, wheat, and oats. The introduction of a cultivated crop into the rotation was found to become more important as the conditions for the production of a maximum total crop were more unfavorable, especially if due to a dry season. It was found that wheat is a more particular crop than oats and requires a better place in the rotation.

The culture of Canada field peas and vetch increased the growth of straw in the following crops, but gave no material increase in the yield of grain. This was most marked where the peas were plowed under as green manure or fed off with hogs. Green manuring with peas has so far shown no benefits over a summer fallow.

At the end of 8 years land growing wheat and corn alternately is producing better total crops of wheat than land growing wheat alternately with vetch and with summer fallow. Manuring land growing wheat alone has so far not been profitable, but a decided profit was secured in manuring land for corn. Where the corn crop was manured a residual effect was observed for at least 4 years.

It is believed that in the best rotations for South Dakota the land should be sown to some perennial grass for a short term of years and that brome grass is well adapted to this use.

Flax was not more exhaustive of the fertility of the soil than the other grain crops.

Results of culture experiments in 1905 (*Ghodiechnuï Otchet Ploty. Selsk. Khoz. Opuutu. Stantzii, 11 (1905), pp. 25-72, 125-127*).—In a dry season the influence of the bare fallow and of the depth of working the soil was very feeble, but the use of barnyard manure in growing leguminous forage plants gave good results. Of different commercial fertilizers used the phosphates were most effective, giving an apparent increase of 16.5 per cent in the cereal crops and of 25 per cent in the crop of sugar beets. The leading varieties of winter wheat were Banat and Champagne, both early sorts, yielding 1,770 kg. of grain per hectare, followed by Don, a medium early variety, with about the same yield.

Owing to the dry season the spring wheat varieties gave but small yields,

with indications that Oulka among the soft wheats and Garnovka and Epi noir among the hard wheats, are best adapted to the region.

Some varieties of barley, including Stockmannsoder, Minnesota, and English D, matured in 101 days, while several others, including Montana Chevalier, required 114 days. The heaviest grain-yielding varieties were Escourgeon du Midi, Bavarian, Hungary, and Chevalier, and the lightest grain-yielding varieties were Svalöf, Pedigree, Wisconsin, and Pomelle. The results further showed that Escourgeon du Midi ranked first in stooling capacity and produced the largest number of grains per head, and that Auvergne occupied first place in the weight per thousand grains.

The blossoming of barley, C. FRUWIRTH (*Fühling's Landw. Ztg.*, 55 (1906), No. 16, pp. 544-553).—The author reports the results of his own observations on the process of blossoming in the different kinds of barley and reviews the observations made by other investigators in this same line of work.

The respiration of barley, O. QVAM (*Tidsskr. Norske Landbr.*, 13 (1906), No. 6, pp. 263-284).—Investigations were conducted to establish the relation between the germination of seeds and the amount of carbon dioxid given off in the process of germination, and to devise ultimately a method by which the more rapid determination of the respiration of seeds might be substituted for germination tests. Similar work by other investigators is described, together with a report on the methods and the apparatus used by the author. In the tests made it was observed that the quantity of carbon dioxid respired by the seeds increased with the increase in temperature and the moisture content of the grain.—F. W. WOLL.

The study of corn, V. M. SHOESMITH (*Kansas Sta. Bul.* 139, pp. 223-249, figs. 12).—This bulletin is a guide in elementary corn judging. Notes on the history, types, and varieties of corn, rules for judging, discussion of points of the score-card, and a description of corn breeding and improvement are given.

Cotton culture in Korea (*Diplo. and Cons. Rpts.* [London], 1906, No. 654, pp. 11).—A report is given on the result of experiments in cotton culture in Korea. It is shown that upland cotton is apparently well adapted to that country, the crop being considerably heavier than that of the native plant.

In a comparison of the 2 types of cotton the only difference in season observed was in the bursting of the pod, which was later in the upland cotton on account of the larger boll produced. Upland cotton gave a larger yield than the native variety even when the buds and superfluous shoots were not pinched out. The upland type not only gave a greater percentage of ginned cotton than the native plant, but the fiber was also longer and finer. It is estimated that about 298,200 acres of cotton are grown in Corea, and that this area represents about 4.5 per cent of the total cultivated land of the country.

Improvement of cotton by seed selection, T. THORNTON (*West Indian Bul.*, 7 (1906), No. 2, pp. 153-170).—A general discussion of the subject is given and the work with seed selection in Barbados during 1905-6 is described. It is stated that out of 264 plants first selected in the field only 14 gave satisfaction in all the characteristics examined. In determining the qualities of the samples the length of staple, the proportion of lint to seed, the proportion of weak fibers, diameter of fibers, silkiness, and fineness was considered, and the data thus secured are given in a table.

A test of commercial cultures for legumes, G. C. BUTZ (*Pennsylvania Sta. Bul.* 78, pp. 13).—Seed of alfalfa, vetch, soy beans, and cowpeas inoculated with a commercial culture was compared with the same kinds of seed not so treated in flowerpots filled with sterilized sand to which was added a

sufficient quantity of mineral plant food. The object of the experiment was mainly to test the activity of the bacteria by the production of root nodules. The germination in all cases seemed to show no effect due to the treatment. As to growth, alfalfa and soy beans showed no decided advantage from the use of the commercial culture. In the case of vetch the bacterial culture had apparently been effective in one pot. With cowpeas slight differences in favor of inoculation were also perceptible.

The same experiment was carried out in the field and the results in general confirm those obtained with pot culture. The soy beans which produced no nodules in the pot-culture tests showed a decidedly heavy production in the field, and this was apparently in favor of the inoculation.

Culture tests with potatoes in 1905, H. J. DANNFELT and S. RHODIN (*K. Landbr. Akad. Handl. och Tidskr.*, 45 (1906), No. 2, pp. 92-131).—A report on experiments conducted by the Royal Swedish Agricultural Academy in 9 different counties of Sweden.

In the fertilizer tests at the experiment station of the Royal Swedish Agricultural Academy the relative value of nitrate of soda, Norwegian lime niter, ammonium sulphate, and calcium cyanamid was studied. In each case 53.4 lbs. of nitrogen was applied per acre, with 134 lbs. of potash in 37 per cent potash salt, and 50 lbs. of citric-acid soluble phosphoric acid in the form of Thomas phosphate. The highest average yield, 27,871 lbs. per acre with a starch content of 12.5 per cent, was secured with lime niter, and the lowest, 21,108 lbs. with 13.4 per cent of starch content, with no nitrogen. Calcium cyanamid ranked first in starch production with 3,495 lbs. per acre, the starch content of the tubers being 12.7 per cent, and was followed by ammonium sulphate, lime niter, and nitrate of soda in the order given, with no nitrogen standing last with a yield of 2,828 lbs. Calcium cyanamid was most profitable and nitrate of soda least so.

Planting from May 5 to 22 gave better results than planting earlier or later. Minimum and optimum temperatures for germination of potatoes were determined as 4 to 5° C. and 10 to 12° C., respectively. Whole medium-size potatoes produced the highest yields, outranking different kinds of cut sets and small whole tubers. Planting 50 by 25 cm. apart gave the best results, but for convenience in cultivation it is recommended that the rows be placed 60 cm. apart with plants from 15 to 20 cm. in the row. Planting 10 cm. deep gave better results than planting 15 cm. or 5 cm. deep.

In the variety tests the largest yields of tubers were obtained from Evergood, Chieftain, and Nero Guardian, and the highest yields of starch from Brocken, Diana, Modrow Industrie, and Sas. In starch content Brocken and Vega ranked first with 19.5 per cent, being followed by Deutscher Reichskanzler with 18.5 per cent, and Saxonia with 17.1 per cent. All the varieties mentioned were quite resistant to disease except Diana and Saxonia.

Observations for a series of years on Swedish farms have shown that the yields of Magnum Bonum during late years have been somewhat higher than before, while the starch content and the palatability of the tubers have decreased. The disease resistance of the variety is essentially unchanged.

The seed of 3 strains of Magnum Bonum potatoes, imported from Scotland, showed a higher productive capacity and a greater resistance to disease than acclimated home-grown seed, but in starch content the tubers from the Scotch seed stood lower than those from the home-grown seed.—F. W. WOLL.

Potato culture experiments, 1905, M. WEBBULL ET AL. (*Malmö. Läns K. Hushåll. Sällsk. Körtidskr.*, 1906, No. 1, pp. 120-169).—Cooperative experiments were conducted at 25 different farms in southern Sweden. Of the varieties

under test Agnelli headed the list with a yield of 26,700 lbs. of tubers and 4,486 lbs. of starch per acre, the average starch content being 16.8 per cent. Fürst Bismarck, the variety ranking first in starch content with 19.5 per cent, yielded 18,307 lbs. of tubers and 3,569 lbs. of starch per acre.

In fertilizer experiments, in which an application of 223 lbs. of nitrate of soda and 178 lbs. each of 20 per cent superphosphate and 37 per cent potash salt was used, the yield of potatoes was apparently increased from 20,897 lbs.—the yield of the unfertilized plats—to 24,956 lbs. per acre. The quantity of starch produced per acre on the unfertilized plats was 4,103 lbs. and on the fertilized plats 4,521 lbs. The use of the fertilizer, on the other hand, seemed to have decreased the starch content from 19.7 to 18.2 per cent.

In another series of experiments with the same varieties of potatoes the effect of the application used in the previously described tests was compared with the results secured from the use of 134 lbs. each of nitrate of soda, 20 per cent superphosphate, and 37 per cent potash salt, given with 17,800 lbs. of barnyard manure per acre. The check plats yielded 17,827 lbs. of tubers per acre, the plats receiving commercial fertilizers alone 21,529 lbs., and the plats treated with commercial fertilizers and barnyard manure 24,048 lbs. The yield of starch for the 3 series of plats was 3,284 lbs., 3,622 lbs., and 4,121 lbs. per acre, and the average starch content 18.3, 16.8, and 17.1 per cent, respectively.—E. W. WOLL.

The influence of the vegetative period and of the fertilizer used on the chemical composition of potato tubers, P. VAGELER (*Fühling's Landw. Ztg.*, 55 (1906), No. 16, pp. 556-563).—It is pointed out from the results of experiments that the specific gravity and the content of dry matter increase with the length of the vegetative period. Mineral matter and nitrogen were not taken up by the tubers after the end of July. As the vegetative period progressed the quantity of stored starch increased, the increase being greatest in August, but somewhat reduced in September.

A general application of lime, barnyard-manure, or the two fertilizers given together, increased the water content, ash, chlorin, potash, total nitrogen, nitrogen-free extract, sugar, and dextrin of the tubers. The use of barnyard manure increased the quantity of crude fiber, while liming reduced it. Without a general application the use of potash increased the water, ash, chlorin, potash, and protein content, and in a lesser degree the nitrogen-free extract and sugar content, while phosphoric acid increased in a lesser degree the moisture and ash content, the quantity of nitrogen compounds, with the exception of the amid and total soluble nitrogen content, and nitrogen-free extract. The nitrogenous fertilizers largely reduced the specific gravity, ash, phosphoric acid, starch, and crude fiber, while the quantity of all other components was increased by this treatment.

In connection with liming, applications of potash gave an increase in the moisture content, ash, nitrogen-free extract, insoluble albuminoids, and starch. The use of phosphoric acid remained neutral with reference to water, total ash, chlorin, potash, proteids, and sugar, but its use increased the specific gravity and the phosphoric acid, total and insoluble nitrogen, and crude-fiber content, while the quantity of soluble ash, soluble amid, and albuminoid substances and starch were greatly reduced. An application of nitrogen favored an increase in specific gravity, water, phosphoric acid, and all nitrogenous substances with the exception of albuminoids. The quantity of total ash, soluble ash, chlorin, potash, starch, and to a very small degree crude fiber, were reduced through nitrogen fertilization.

With barnyard manure as a general application potash increased the water

content, the quantity of all ash components with the exception of phosphoric acid, the insoluble nitrogen, albumin and albuminoid nitrogen, nitrogen-free extract, and the starch. All other constituents, as well as the specific gravity, were reduced. Phosphoric acid increased the quantity of water, the ash constituents with the exception of the soluble ash, which was greatly depressed, the nitrogen compounds, nitrogen-free extract, starch, and crude fiber. An application of nitrogen increased the quantity of water, the total and soluble ash, chlorin, and especially the nitrogen content, while it had no effect on the starch content and reduced the specific gravity.

Where lime and barnyard manure were used as a general dressing, potash applied as a fertilizer favored an increase in specific gravity, total ash, soluble ash, chlorin, potash, phosphoric acid, albuminoid nitrogen, and starch; showed no effect on the moisture and nitrogen-free extract content, and decreased the quantity of all other constituents. Phosphoric acid had a favorable influence on the water, total ash, chlorin, potash, phosphoric acid, total and albuminoid nitrogen, nitrogen-free extract, starch, and crude fiber. This result was analogous to its action where barnyard manure alone was given as a general application. The use of a nitrogenous fertilizer increased the moisture content, the ash constituents, total and soluble nitrogen, albuminoid nitrogen, nitrogen-free extract, and crude fiber, and reduced the quantity of the other substances.

Trial tests with rye, F. HANSEN ET AL. (*Landmandsblade*, 39 (1906), No. 24, pp. 298-300).—Results secured at the state experiment stations for plant culture in Denmark showed that during the period 1895-1904 Bretagne and Petkus rye were the most valuable varieties under test.—F. W. WOLL.

Comparative tests with varieties of sugar cane, C. F. ECKART (*Hawaiian Sugar Planters' Sta., Div. Agr. and Chem. Bul.* 17, pp. 20).—The results of a plant crop of 17 varieties of sugar cane were reported in Bulletin No. 12 of this station (E. S. R., 17, p. 761), and the data given in this bulletin refer to the ratoon crop of this same planting. These results, including sugar yields and the quality of the juices, are compared with the plant cane results previously reported. In addition, the results secured with introduced seedling canes together with a few native and other varieties are also given. The tables presented also include information regarding the check of growth in the cane due to the winter season and the relative rapidity of recovering normal development under favorable conditions. All results are tabulated without comment.

Macaroni or durum wheats, J. H. SHEPARD (*South Dakota Sta. Bul.* 99, pp. 105-115).—This bulletin is a continuation of Bulletin 92 of the station (E. S. R., 17, p. 269). As heretofore, comparisons with Russian, Mediterranean, and miscellaneous macaroni wheats were made, and the data secured are tabulated with brief comments.

Kubanka 5639 for 1904 and 1905 yielded the largest per cent of protein. It was observed that the total protein was less in all varieties in a wet season than in a dry one, but it is considered evident that the durum wheats will not suffer protein diminution in that climate.

The bread and macaroni tests showed that the loaf volume did not vary greatly among the better varieties. Arnautka and Wild Goose, two heavy yielding varieties, were compared with the other sorts, but they showed no particular superiority in any of these tests.

It is pointed out that the durum wheats carry more protein than the bread wheats, but that the gliadin content is usually lower, and that apparently the greater per cent of gluten offsets in a measure the lack of gliadin in bread making.

The results secured during the years 1904 and 1905 are regarded as reaffirm-

ing those reported in 1903. On the strength of these experiments Kubanka 5639 is recommended for more general use.

HORTICULTURE.

Studies in plant breeding in the Tropics, R. H. LOCK (*Ann. Roy. Bot. Gard. Peradeniya*, 2 (1904), No. 2, pp. 299-356; (1905), No. 3, pp. 357-414).—The author gives brief historical notes on the general subject of plant breeding, giving special attention to the results secured by Mendel and the confirmation of these by more recent experimenters.

Details are also given of a large amount of the experimental work by the author in crossing various cultivated peas with native peas. The results obtained in these experiments are in the main confirmatory of those secured by Mendel, although several exceptions occurred. A bibliography of 80 papers on various phases of plant breeding is included.

Truth about ginseng culture, W. M. EVANS (*Rural New Yorker*, 65 (1906), No. 2957, p. 727).—The author discusses the condition of 3 ginseng plantations of considerable size which he recently visited. The ginseng had been planted for 3 or 4 years and involved an initial outlay of considerable money. Blight has seriously injured the growth and productiveness of the plantations in every instance. Two of the plantations have been practically abandoned and the third has not begun to pay expenses.

Seed packing for the Tropics, W. H. PATTERSON (*Gard. Chron.*, 3, ser., 40 (1906), No. 1033, p. 255).—Germination tests were made of seed sent from England to the West Indies in ordinary paper packets. The tests were made (1) on receipt of the seed, (2) at the end of the month, (3) at the end of 2 months. The seeds germinated well at the end of the first and second months and fairly well at the end of the third month in the case of beans and peas. It is not deemed advisable to attempt to grow seeds that have been kept for a longer period than this in the Tropics.

Data are also given for a similar test with a large number of vegetable seeds sent out from Kew. As a result, the writer thinks it is not so much a question of the temperature and moisture as of ravages of small ants and weevils after the arrival of the seed in the Tropics.

Fruit industry (*Daily Consular and Trade Rpts.* [U. S.], 1906, No. 2676, pp. 1-6).—Statistics are given showing the total exports of fruits from the United States to different European countries in 1905. The largest amount of green and canned fruit is shipped to Great Britain, while Germany is our greatest purchaser of dried fruits, many of which are used for the manufacture of jelly, marmalade, etc. The total exports of fruit for the year ended June 30, 1906, were valued at \$14,964,158. In 1904 the value was \$20,347,699, and in 1905 \$15,297,391.

Statistics and fruit-crop report, A. W. PEART (*Proc. Conference Fruit Growers Canada*, 2 (1906), pp. 19-26).—Tables of statistics are given showing the number of bearing and non-bearing fruit trees in Canada and each of the provinces in 1901, the yields of the same in bushels and an estimate of the value. Data on the yields, value, and acreage of grapes and small fruits are also given, and tables showing the apples exported from Canada during each of the 10 years previous to June 30, 1904, and the countries to which they were shipped.

Varieties of fruit for the home orchard, H. L. PRICE (*Virginia Sta. Bul.* 161, pp. 123-144, figs. 13).—Brief descriptions are given of a few of the better varieties of each of the different orchard and small fruits which may be

grown in the home garden. Directions are also given for laying out and planting orchards.

The drying up of orange trees as the result of autumn siroccos, F. BOUF and P. GENET (*Bul. Soc. Hort. Tunisie*, 5 (1906), Nos. 18, pp. 20-27, *dgms.* 4; 19, pp. 52-58, *dgms.* 9).—The authors made a study of why the drying wind of the fall sirocco is so much more injurious to citrus fruits than earlier in the season. Anatomical studies were made of the leaves of a number of citrus fruits such as the orange, citron, mandarin, pomelo, sour orange, etc.

Generally it was found that the resistance to the drying wind was greater in young leaves than in old leaves. Hence, in the spring and summer, when the circulation of sap is most rapid, these winds are less injurious than later when the leaves become older and sap circulation is much slower. In order to avoid the injurious effects of the drying winds so far as possible it is suggested that the trees be pruned in summer time. This will cause new shoots to push out, bearing fresh young leaves, which will be more resistant at the time of the autumn sirocco. This pruning must be done with considerable discretion, of course, as the removal of any large parts of the leaves would seriously injure the maturing of the fruit.

It was also found that when the cultivated oranges are grafted on sour orange stock the sap circulation was not as free as when other stocks were used. Hence stocks other than sour orange are urged.

Oil palm culture, L. STRUNK (*Tropenpflanzer*, 10 (1906), No. 10, pp. 637-642).—Physical analyses are given of the fruit of a number of varieties of oil palm grown in Kamerun and also of the fruit produced on seedling trees from productive mothers. With the better varieties of oil palms the proportion of kernel to shell was usually greater than 1:2, while in the varieties usually grown the relation of kernel to shell varied from 1:3 to 1:4. Seedlings grown from productive oil-bearing mothers did not uniformly inherit the tendency to oil productiveness. Seed from the seedlings, however, which were rich in oil is to be planted to see if a strain rich in oil can not be secured which will come true to seed.

Mulberries, H. H. HUME and F. C. REIMER (*North Carolina Sta. Bul.* 194, pp. 39-59, *figs.* 11).—This bulletin gives popular directions for the propagation, planting, cultivation, and pruning of mulberries, with descriptions of 15 of the more important varieties.

One of the characteristics claimed for the mulberry is that the fruit ripens over a period of several months. The tree is a rapid grower and the abundance of fruit produced makes it specially useful for planting around stables and chicken and stock yards. As the fruit is greatly relished by birds a few mulberry trees planted in the orchard serves as a protection to other more valuable fruits.

Canning pineapples (*West Indian Bul.*, 7 (1906), No. 2, pp. 178-185).—Statistics are given showing the exports of fresh and canned pineapples from the Bahamas, with an account of the methods of canning pineapples followed in Hawaii, the Bahamas, Jamaica, and the Straits and Federated Malay States.

Viticulture in New Zealand, R. BRAGATO (*New Zeal. Dept. Agr., Vit. Div.*, 1906, pp. 60, *figs.* 33).—This is a handbook for the use of viticulturists in New Zealand, giving detailed directions for the culture of grapes.

Green manuring in tea culture in India, H. H. MANN and C. M. HUTCHINSON (*Indian Tea Assoc.* [Pamphlet] 2, 1906, pp. 43, *pls.* 10).—The value of a large number of plants as green manure for tea in India is discussed at length and the results given of experiments made to determine the green manuring value of a few of the more prominent ones.

One of the best of the leguminous trees appears to be the sau (*Albizzia stipulata*). Statistics are given which show that the average yield of tea per bush near sau trees in one instance was 1.7 lbs., while on the same plat farther away from the trees the yield was but 0.8 lb. per bush. In another instance the yield is shown to have been increased 50 per cent when the bushes were grown near sau trees. The good effects of the sau tree are believed to be due in some instances to (1) the light shade that it casts, (2) the retention of the rainfall, (3) the manurial value of the flowers and fallen leaves, (4) the condition of the soil brought about by the extensive and ramifying root system, and (5) the ability of the trees to utilize free nitrogen through the nodules on the roots of the trees.

The root radius of trees 5 years old in one instance was found to be 55 ft., and the depth of the tap root $8\frac{1}{2}$ to 10 ft. Analyses of the soil near sau trees showed a slightly larger percentage of organic matter and a little more nitrogen than in the soil some distance away from the trees. The method of growing this tree on tea plantations, as well as that of the dadap (*Erythrina lithosperma*) and boga-medeloa (*Tephrosia candida*) is given at length.

Another valuable plant for green manuring tea is the bean *Phascolus mungo*. The increase in yield in tea where this plant has been used has varied from 12 to 16 per cent. The value of such other plants as *Crotolaria striata*, peanuts, mustard, and *Sesbania cannabina* is also discussed.

Treatment of deteriorated tea, H. H. MANN (*Indian Tea Assoc. [Pamphlet] 4, 1906, pp. 24*).—It has been noted that as tea plantations increase with age the quantity of tea obtained is greatly lessened. The author considers the various factors which cause this and gives suggestions on methods of cultivation, pruning, draining, green manuring, and the use of such fertilizers as cattle manure, oil cake, etc., for rejuvenating such old plantations.

Report on a sample of cocoanut "water" from Ceylon, W. R. DUNSTAN (*Trop. Agr. and Mag. Ceylon Agr. Soc., 26 (1906), No. 5, pp. 377, 378*).—The water in the cocoanut was analyzed with a view to the manufacture of sugar from it should it be found in sufficient quantities. The results of the analyses were as follows: Water, 96 per cent; ash, 0.5 per cent; mannitol, 1.8 per cent; cane sugar, 0.1 per cent; glucose, 0.9 per cent; acid constituents, 0.48 per cent. A sample of water from ripe cocoanuts contained 2.6 per cent of cane sugar, 0.5 per cent of glucose, but no mannitol. Based on these data it is concluded that the manufacture of sugar from cocoanut water is not likely to be profitable, even though the material were a waste product.

Experimental studies on the mechanical effects of frost on fruit and forest trees, P. SOBAUER (*Landw. Jahrb., 35 (1906), No. 4, pp. 469-525, pls. 5*).—The details are given of an extensive botanical study to determine the physiological effects of early and late frosts on the mature and immature wood of a large number of fruit and forest trees, including the cherry, pear, apple, rose, linden, elm, beech, horse-chestnut, spruce, and oak. The effect of frost on different wood tissues is shown in numerous plates illustrating cross sections of injured wood.

Among the more important conclusions drawn are the following: The same degree of cold has a different effect on trees, depending on whether the twigs are still young and green or whether they are more nearly ripened and filled with reserve material. In the latter case the effects are chiefly mechanical, and are marked by a discoloration of the cell contents and a browning of the cell walls, while in the former, if the young twigs are not killed outright, the effects are primarily mechanical.

The discolorations occur principally in the cambium and pith of the twigs,

especially in the newest layers of permanent tissue, and affect corresponding zones in the leaf stems. In most woods the thin-walled parenchyma, containing crystals of oxalate of lime, is first affected. The first breaks or openings in the vascular bundles occur either in the region of the hard bast fibers or in the boundary region between the collenchymatous tissues and the endodermis. The spiral vessels are especially susceptible to injury. In the fine veins of the leaves these spiral vessels frequently showed a brown discoloration when the surrounding mesophyll was uninjured.

Frost, however, does not act uniformly. Some of the tissue in the leaf may be brown while the remaining parts are still green. The danger from frost is greatest where the bud is attached, because of the large amount of parenchyma in proportion to the solid ring growth at this place. Frost injury is confined to the region affected and does not spread to new tissue as does a fungus disease.

In addition to discoloration, frost causes many mechanical injuries, and the younger the twigs the greater the amount of such injury. Openings in the leaf and bark surfaces caused by frost are most numerous where the soft parenchyma tissue is united with more solid tissue. Injuries on the upper side of the leaf are generally distinguished by the collenchymatous tissue being split apart from the parenchyma lying underneath.

Eruptions of the vascular cylinder are generally manifested either in radial clefts within the medullary rays or in tangential cracks within the cambium region. In addition, many cavities appear in the pith and the bark parenchyma. The separated tissue within the cambium region gradually heals over, often presenting the appearance of a 2-years' ring growth. Such appearances are most frequently found directly under a bud place.

The permanent wilted appearance of frost-injured twigs is due to the uplifting and splitting of the plant tissue. Leaves which when left on the branch show a wilted condition because the water in the tissue is frozen or has been forced out of the cells regain their normal turgescence on placing the stems in water.

English walnuts in New York, A. C. POMEROY (*Amer. Agr.*, 78 (1906), No. 14, pp. 289, 297, figs. 3).—The author states that in 1876 English walnuts were planted in Niagara County, New York, and that at the present time some of the better trees give an average annual yield of about 20 bu. of nuts. Suggestions are made on the culture of English walnuts and illustrations of the trees and nuts are given.

The pecan and its culture, H. H. HUME (*Petersburg, Va.: Amer. Fruit and Nut Jour.*, 1906, pp. 159, pls. 10, figs. 38).—A compact treatise on pecans, treating of the botany, varieties, various cultural operations including harvesting and marketing, and the diseases and insects, the uses of the nuts, and a bibliography of 23 papers on the subject.

Ornamental trees, shrubs, and herbaceous plants in Minnesota, S. B. GREEN (*Minnesota Sta. Bul.* 96, pp. 239-351, figs. 105).—Brief popular descriptions are given of a large number of ornamental trees, shrubs, and herbaceous plants which can be successfully grown in Minnesota, with some general rules for planting, making lawns, planting for special effects, and winter protection of perennial plants. A prominent feature of the bulletin is the unusually large number of illustrations of different ornamental plants showing their uses for adornment.

FORESTRY.

Chestnut in Connecticut and the improvement of the woodlot, A. F. HAWES (*Connecticut State Sta. Bul.* 154, pp. 41, pls. 11, figs. 3).—"The purpose of this bulletin is to serve as a guide for the better management of our woodlots." Suggestions on making improvement thinning, and tables based

on the stem analyses of over 400 chestnut trees grown in Connecticut, showing the volume in cubic feet and cords of trees of different diameters, and the application of volume tables in estimating the yield of stands are given.

The uses of chestnut for fuel, ties, piles, telegraph and telephone poles, and lumber are discussed, and data given on the relative profits in growing and handling each of these. The cost of cutting, logging, and sawing chestnut lumber is placed at between \$5 and \$6.25 a thousand; of cutting, logging, and sawing ties 15 cts. each; and of hewing ties 10 cts. each. For cutting and peeling piles and poles the cost is usually 1 ct. a linear foot, while the cost of hauling 3 miles varies from 30 to 40 cts. in the case of a 25 ft. pole, to \$3 with a 65 ft. pole. Cordwood costs 90 cts. to \$1.25 a cord for cutting, and from \$1.50 to \$2 a cord for hauling 6 miles.

As to the relative profits of the different forms of timber it is stated that straight trees pay best when cut into poles and lumber pays better than ties or cordwood. Tables are given showing the average height and diameter of sprouts and seedlings of various ages from 20 to 108 years old. The increase in volume of trees varying from 3 to 31 in. in diameter is also shown in tabular form, as well as the average and minimum length of time required for a chestnut tree to produce various numbers of ties.

Relative to the time of cutting the chestnut, the author states that if for fuel alone the trees may be cut when they are 20 in. in diameter. If sound and straight enough for poles they may be profitably left until 25 in. in diameter. A chestnut forest should not be left standing much longer as this is the age at which it reaches its main height growth: it is likely to be attacked by rots and deteriorate if left longer. A table is given showing that both sprouts and seedlings have a larger proportion of diseases as they reach 20 in. and above than before this time.

The sprouting ability of chestnuts seems to be equally good all over the state and to be undiminished through a number of generations. Some data are given showing the value to railroad and other companies, requiring a continuous supply of timber, in establishing permanent forests in Connecticut.

The improved chestnut in lower Austria, E. BÖHMERLE (*Centbl. Gesam. Forstw.*, 32 (1906), Nos. 7, pp. 289-306; 8-9, pp. 355-367, figs. 4).—An account is given of the growth in many different locations of the cultivated chestnut. Statistics showing the diameter measure breast high of stands of different ages, the use of the wood for commercial purposes, and its characteristics green and dry are also considered.

Bassia latifolia gum, P. SHANKERNATH (*Indian Forester*, 32 (1906), No. 8, pp. 399-402).—Analyses of the gum of Mohwa trees indicated that it might be of value as a substitute for Balata, as it has very similar composition and properties. Tapping experiments, however, showed that the amount of gum which can be obtained from the trees is too small to make the working of such trees practicable. It required about 20 mature Mohwa trees to yield 1 lb. of this substitute for gutta-percha. The text contains analyses of 3 samples of the gum.

Practical arboriculture, J. P. BROWN (*Connersville, Ind.: Author, 1906*, pp. 460, pls. 58, figs. 82).—This book is made up of a collection of short articles dealing with the various phases of forestry, such as the influence of forests on climates and floods, the planting and care of trees, and the uses of wood for the various purposes of manufacturing, lumber, railroad ties, telegraph poles, wood pulp, etc. The work is of value in calling attention to the importance of forestry, but is in no sense a systematic treatise on the subject.

Forest mensuration, H. S. GRAVES (*New York: John Wiley & Sons; Lon-*

don: Chapman & Hall, Ltd., 1906, pp. XIV + 458, figs. 55).—This is designed as a text-book for the use of students in forestry and as a reference book for practical foresters and lumbermen. It gives detailed directions for scaling and measuring timber with descriptions of log rules and instruments used in determining the height of trees. Other matters, such as volume tables, form factors, contents of stands, age and growth of trees, yield tables, legislation regarding the measurement of logs, etc., are also included.

Report of the forest seed-testing station at Eberswalde, SCHWAPPACH (*Ztschr. Forst u. Jagdw.*, 38 (1906), No. 8, pp. 505-515, fig. 1).—A general report is given on the seed-testing work of the station during 3 years, 1903 to 1906.

In the testing of seed of a large number of species of forest trees the germination was considerably more rapid and complete in light than in darkness.

Experiments were made in testing the germination of seeds from trees varying from 20 to 150 years old. The average percentage germination of seed from trees 20 to 40 years old was 70; with trees 80 to 100 years old, 90; with 2 stands of trees 140 years old, 60, and with 1 stand 150 years old, 90. The heaviest seeds were obtained from the oldest trees.

In the test of light *v.* dark-colored seeds, the dark-colored seeds gave much the better germination. A test was also made of the germination of seed stored for different periods but without conclusive results.

Forest seed analyses and control, A. FROX (*Ann. Sci. Agron.*, 2, ser., 10 (1905), II, No. 3, pp. 332-435, figs. 7; 3, ser., 11 (1906), I, No. 1, pp. 133-153, figs. 22).—The author treats of the work done in foreign countries in the control and analyses of forest seeds.

The various stations having this work in charge are described and the average results secured with a large number of forest seeds relative to maximum, minimum, and average germination, percentage of purity, etc., are brought together. The technique observed in analyzing and testing the seeds is given with considerable detail and suggestions offered regarding standards which should be observed in making the tests for purity, germination, etc.

The hardness of woods, G. JANKA (*Die Härte des Holzes*. Vienna: W. Frick, 1906, pp. 32, figs. 7).—This is a report issued by the forestry experiment station in Mariabrunn, and shows the relative hardness of a large number of different woods when dried and when saturated with water, and in some cases when impregnated with oil. The hardness was determined by pressing into the wood either radially or longitudinally a small iron ball or half-ball. In some instances an iron wedge, a cube, or an ax was inserted. Extensive tables are given showing the results obtained.

Generally speaking the results show that when the tests were made longitudinally the wood was about 30 per cent more difficult of penetration in the case of conifers and 20 per cent more difficult in the case of broad-leaf species than when a radial pressure was applied. Wood which has grown rapidly, as shown by the widths of the annual rings, is less hard than that which is grown more slowly. Likewise, any increase in the specific gravity of wood is followed by an increase in its hardness.

Soaking the wood for 7 months so that it became saturated with water resulted in reducing its hardness in the case of conifers about 50 per cent and in the case of broad-leaf trees 35 per cent. Saturation with oil also decreases the hardness of the wood. It was found that the ax penetrated wood in a slanting manner about 35 per cent easier when the wood was moist than when air-dried.

Forest fires, A. AKERMAN (*Mass. Forest Serr. Bul.* 5, pp. 24).—The injuries resulting to forests from fires are discussed, and estimates given of the annual

losses in Massachusetts, with suggestions for extinguishing and preventing forest fires. The texts of the Connecticut, Massachusetts, and Minnesota forest-fire laws are given in the appendix.

DISEASES OF PLANTS.

Some fungus diseases of cultivated plants in France, G. DELACROIX (*Extract from Bul. Soc. Mycol. France, 21 (1905), No. 3, pp. 1-23, figs. 6*).—Brief descriptions are given of the occurrence of *Septoria cucurbitaccarum* on melon leaves, *Septoria* on tomatoes, a disease of palms due to *Exosporium palmivorum*, a disease of almonds due to *Fusicoccum amygdali* n. sp., and a disease of oleanders caused by *Phoma oleandrina* n. sp.

Some parasitic fungi of tropical cultivated plants, G. DELACROIX (*Extract from Bul. Soc. Mycol. France, 21 (1905), No. 3, pp. 24-37, figs. 10*).—Among a number of diseases of economic plants that are caused by attacks of parasitic fungi, the author describes the following new species: *Collectotrichum theobromicolum* occurring on the fruit of cacao, *C. brachytrichum* on the leaves of cacao, *Glaeosporium mangifera* on mango leaves, a number of species of fungi on rubber trees, *Glomerella artocarp*i on bread fruit, *Diplodia perseana* on the avocado, and *Phyllosticta cinnamomi* on the leaves of cinnamon.

Blight and powdery mildew of peas, J. M. VAN HOOK (*Ohio Sta. Bul. 173, pp. 231-249, figs. 12*).—After an introductory note by the botanist of the station calling attention to the presence and injury due to these diseases on a crop of peas grown for canning purposes, a description is given of the different diseases and their causes, together with suggestions for their prevention.

The blighting of field and garden peas is due to the fungus *Ascochyta pisi*, and from the author's investigation it was found that the infection spreads largely through the use of diseased seed. Having determined this fact a series of experiments was carried on to test the germination of peas affected with the blight fungus and also the effect of seed treatment and the value of spraying and tying up the vines as preventives. Seed treatment proved valueless, as the fungus is less susceptible to fungicides than the germ of the seed. For a similar reason heating the seed failed. Tying up the vines and spraying, while increasing the crop slightly produced peas that were much freer from disease than others and on that account are valuable in growing healthy peas for seed purposes.

Planting healthy peas in soil free from fungus is recommended as the best means of reducing the loss of blight. The author states that the fungus causing pea blight is known also to attack alfalfa, chick-peas, common beans, and hairy vetch. All varieties of the common bean examined were affected, but some much more than others.

In the note on the powdery mildew (*Erysiphe communis*), the author states that by spraying with Bordeaux mixture the disease may be readily prevented.

Anthraxnose of beans and peas, H. BLIX (*Rev. Hort. [Paris], 78 (1906), No. 14, pp. 335-337*).—Descriptions are given of the anthracnose of beans due to *Collectotrichum lindemuthianum* and of peas caused by *Ascochyta pisi*, with suggestions for their prevention. In experiments carried on in 1901 and 1903 in which beans were thoroughly sprayed with Bordeaux mixture, relatively little disease was observed, and the author thinks that a similar treatment would be efficient in preventing the anthracnose of peas.

A disease of ginseng due to *Phytophthora*, J. M. VAN HOOK (*Spec. Crops, n. ser., 5 (1906), No. 45, p. 94*).—The author describes a disease of ginseng which is due to *Phytophthora omnivora*. The fungus is very common on many

plants and has been observed on many specimens of ginseng submitted for examination.

The author recommends the destruction of all dead plants, spraying with Bordeaux mixture, and frequent changing of location as far as possible or sterilization of soil. In spraying, particular attention must be paid to covering the petioles and stem in the region of the fork, as this seems to be the portion of the plant most subject to attack.

Diseases of beets and mangels, G. MASSEE (*Roy. Bot. Gard. Kew, Bul. Misc. Inform., 1906, No. 3, pp. 49-60, figs. 5*).—Notes are given on a number of diseases to which beets and mangels are subject, among them beet canker, beet rust, leaf spot, mildew, root rot, beet-root tumor, white rust, scab, heart rot, etc. Among the diseases described which are relatively little known in this country are the beet canker, due to *Pionnotes beta*, and the heart rot, caused by *Sphaerella tabifica*.

The canker attacks beets and mangels in storage, particularly if the roots have undergone a period of sweating. The fungus causes dingy yellow spots that appear on the surface of the roots. These soon spread, forming irregular nodular gelatinous crusts, involving more or less of the root, until the whole is disorganized and destroyed. The fungus also attacks potatoes, as the author has proved by numerous inoculation experiments, and he believes it is identical with that which has been described as *P. rhizophila*, which is said to attack potatoes and dahlias. The author suggests care in storing, so that the roots should be thoroughly dry, and that every precaution should be taken to prevent sweating in storage.

The heart rot, which has been reported as destructive in some localities, usually manifests itself in August, when the roots have attained a fairly large size. The first indication of its presence is seen in the drooping of the large outside leaves. The appearance is somewhat similar to that of wilting due to lack of moisture, but the leaves do not regain their upright position during the night, and an examination shows a considerable portion of the upper surface of the leaf stalks bleached and studded with minute black points. The fungus grows downward, entering the crown of the root, which is eventually killed. In this destruction the fungus is frequently aided by other fungi, bacteria, nematodes, etc. When symptoms of this disease appear, all affected roots should be pulled and burned or deeply buried.

Perpetuation of potato rot and leaf curl, G. MASSEE (*Roy. Bot. Gard. Kew, Bul. Misc. Inform., 1906, No. 4, pp. 111, 112*).—A description is given of experiments to show the means by which the potato rot (*Phytophthora infestans*) and the leaf curl (*Macrosporium solani*) are perpetuated. Attention is called to the frequent sudden appearance of these diseases and the fact that fields are often destroyed within 24 hours. This widespread destruction has led to an investigation of means of dissemination other than by spores to account for this epidemic form of disease.

The author took a number of diseased tubers, cut them in halves, and planted them in pots, placing the pots under conditions where the temperature, atmosphere, and soil moisture could be controlled. The plants grown in cool, well-lighted, dry houses showed no trace of disease at the end of 2 months, but when one of the plants was removed to a warm house and placed under a bell jar it was blackened and killed by the fungus within 9 days. Similarly marked results were obtained by using potato tubers infested with the *Macrosporium*, showing that this fungus can also be perpetuated by hibernating mycelium present in the tubers.

The experiments seem to indicate that the fungus may be present, but held in

abeyance by atmospheric conditions. When a number of warm, damp days of dull weather intervene the fungus, already present in the tissues, develops with great rapidity. It is believed that the two diseases will not occur in an aggressive form when the climatic conditions are unfavorable to their development.

The root rots of sugar beets, L. PETERS (*Ber. Deut. Bot. Gesell.*, 24 (1906), No. 6, pp. 323-329).—Attention is called to the fact that a number of fungi are concerned in the diseases commonly referred to as beet root rot, and the author describes the characteristic effects produced by *Pythium debaryanum* and *Phoma beta*. In addition to these fungi he states that *Aphanomyces laevis* must be considered as causing a form of rot of sugar-beet roots. Specific differences in the action of these fungi are pointed out.

Top rot of sugar cane (*Queensland Agr. Jour.*, 16 (1906), No. 8, pp. 498-505).—A summary is given of investigations on the top rot of sugar cane, a disease which has been known in Australia for a number of years. In some seasons nearly the whole crop has been a failure, while in other cases the reduction in yield has amounted to over 20 to 50 per cent.

The disease can be first recognized near the center of the heart of the young sprout. The leaves at this very early stage of the disease are paler than the ordinary color, and the heart becomes a yellowish brown, while the expanding leaves are thinner than usual, somewhat dry, and slightly curled. The appearance of the different parts of the cane plant as affected by this disease is described, and the liability of different varieties to disease is considered.

The changes shown in the early symptoms of the disease seem to be the consequence of chemical processes, as neither fungi nor bacteria are to be found in the earliest infected parts of the plant. The chemical changes effect disorganization and death of the plant cells, and the wounds thus made are invaded by various kinds of fungi and bacteria. Various other theories have been advanced as to the cause of the disease, but the author believes that it is due to chemical changes, possibly induced through atmospheric and soil conditions.

Investigations on some diseases of tobacco in France, G. DELACROIX (*Extract from Ann. Inst. Nat. Agron.*, 2, ser., 5 (1906), No. 1, pp. 92, figs. 17).—Extended descriptions are given of a bacterial canker of tobacco due to *Bacillus aruginosus*, several bacterial diseases which follow insect injuries, the mosaic disease of tobacco, leaf spot disease caused by *Bacillus maculicola*, a root rot due to *Fusarium tabacivorum*, a sclerotium disease, several leaf rusts, albinism, chlorosis, etc. The symptoms of the diseases are noted, the organisms, so far as known, are technically described, and the results of inoculation experiments in establishing the causes of the diseases are stated. Brief bibliographies are given of literature relating to each disease and, where known, preventive treatments are recommended.

Tobacco wilt in South Africa, C. P. LOUNSEBURY (*Agr. Jour. Cape Good Hope*, 28 (1906), No. 6, pp. 784-803, figs. 9).—The author describes a disease of tobacco which is attributed to the potato moth or leaf miner (*Gelechia operculella*). This disease is in some respects quite similar to the wilt of tobacco, as described from this country and from Japan. Notes on these two diseases are appended.

A new fungus of economic importance, R. E. SMITH and ELIZABETH H. SMITH (*Bot. Gaz.*, 42 (1906), No. 3, pp. 215-221, figs. 3).—Among the investigations that are being carried on by the California Experiment Station is that on a destructive rotting of lemons which occurs in southern California and within a few years has become a serious trouble to lemon growers and shippers. The rot is usually called brown rot to distinguish it from the blue mold

or *Penicillium* rot. The affected lemons are easily distinguished from those attacked by the blue mold, although the latter fungus rapidly follows the other and soon covers the decaying fruit. The odor of the lemons affected by the brown rot is characteristic, and the peculiar rancid smell can be quickly detected by an experienced person.

When brown rot first made its appearance in packing houses, search was made in the orchard to locate the origin of the trouble, and lemons showing a brownish discolored area on the side or end without any decided softening of the rind were found on the trees. The affected fruit keeps its size, shape, and solidity for a considerable time, when it usually falls to the ground.

Under the conditions of lemon packing this fungus finds its way into the boxes and spots develop on fruit that are apparently sound when put away. The diseased fruits are soon involved together with all those which lie in contact with them. The trouble never spreads in the mass of stored fruit except by actual contact of the healthy lemon with an affected spot. When a large amount of fruit becomes affected, the characteristic odor is very pronounced.

A study was made of the fungus and inoculation experiments showed that it was the cause of the disease. The investigations of the authors showed that it is a hitherto unrecognized fungus which has relationship with a number of genera. Both the genus and species are believed to be new and the organism is described as *Pythiacystis citrophthora*.

A bulletin from the California Station on the nature and control of the disease is promised in the near future.

Revision of the genus *Hemileia*, G. MASSEE (*Roy. Bot. Gard. Kew. Bul. Misc. Inform.*, 1906, No. 2, pp. 35-42, pl. 1).—The author calls attention to the lack of information regarding the aecidial stages of species of *Hemileia*, and suggests that as there are known to be species of *Lecidium* on plants that are also infested by *Hemileia*, probably a form of heteroecism exists in this genus, and that the solution of this problem would be of value in attempts to check the ravages of the parasitic form. He notes also that *Hemileia vastatrix* has been reported as occurring in various regions upon the indigenous species of *Coffea*, and he thinks that it is not necessary to assume that the coffee disease has always been imported with coffee plants from one country to another.

Suggestions are given for the prevention of spread of the disease, and until the aecidial stage is known it is believed that where the nature of the ground and other circumstances permit of spraying, the use of half-normal strengths of Bordeaux mixture is advisable. A note is given from an observer in Tonkin stating that the spread of the disease seems to be checked by the removal of coffee shade.

The author gives amended descriptions of the genera and species, describing 4 species of *Hemileia*, of which *H. vastatrix* and *H. woodii* are known to occur parasitically upon coffee. *H. vastatrix*, which is widely known as exceedingly destructive to coffee, has been reported as occurring in Ceylon, India, China, Java, Sumatra, Singapore, the Philippine Islands, Samoa, Fiji, Mauritius, Madagascar, and numerous places in Africa. *H. woodii* is indigenous in the southern part of Africa on species of *Coffea* and also on species of *Vangueria*, while in Java and Queensland it occurs on gardenias.

A bibliography of the more important contributions relating to the *Hemileia* disease of coffee is appended.

Diseases of coffee with particular reference to *Hemileia vastatrix*, BRIS (*Agr. Prat. Pays Chauds*, 6 (1906), No. 42, pp. 228-247, figs. 2).—Notes are given on the ravages of *Hemileia vastatrix* in Ceylon, Madagascar, Réunion, etc.,

and attention is called to various means that have been tried to combat it. These include the destruction of the affected foliage, spraying and fumigating diseased plants, the influence of location on the disease, resistant varieties, etc.

Spraying was found to be effective under certain conditions, but it is often so expensive as not to be economically advantageous. Liberian coffee and some Java and other hybrids seem to be quite resistant, so far as the author's investigations have been carried. Improved culture seems to be valuable in rendering the plants less liable to injury. Where Arabian varieties are grown, the plantings should not be made in situations where there is too great humidity and heat. The trees should be artificially irrigated where there is a lack of rainfall, selection made of vigorous plants from the nursery, and attention paid to the choice of fertilizers and the keeping down of weeds.

An effective treatment for grape anthracnose, C. P. LOUNSBURY (*Agr. Jour. Cape Good Hope*, 29 (1906), No. 1, pp. 29-35, fig. 1).—After briefly describing grape anthracnose, due to *Glaosporium ampelophagum*, the author calls attention to the varying susceptibility of different varieties to this disease and points out the almost complete resistance of a number of forms. For the prevention of the disease winter treatment with an acid solution of iron sulphate is recommended, and an account is given of experiments in which a vineyard was treated with this solution. Vines that had suffered severely the year before, when given the treatment bore a heavy crop of fruit and but occasional evidences could be found of the presence of any disease in the vineyards.

Investigations on the development of Botrytis cinerea, J. M. GUILLO (*Compt. Rend. Acad. Sci. [Paris]*, 142 (1906), No. 24, pp. 1346-1349).—The author has studied the development of *Botrytis cinerea*, which causes the gray rot of grapes, and has endeavored to ascertain its method of rapid spreading.

Inoculation experiments made upon wounded grapes showed that the spores develop rapidly and in from 36 hours to 3 days are able to cause a pronounced infection. In other experiments it is shown that the *Botrytis* developing normally in contact with uninjured grapes is able to penetrate the epidermis of the fruit and set up an infection within a relatively short time. It is also found that the fungus by its mycelium is able to spread from place to place, so that grapes not immediately in contact are readily infected, even if the spread of the spores by means of the air should be disregarded.

Notes on the grape powdery mildew, P. PACOTTET (*Rev. Vit.*, 26 (1906), No. 655, pp. 9-13).—Attention is called to the perithecial phase of the powdery mildew.

The author believes that the perithecia are formed annually in France in different places and that they play a very important part in the spread of the disease. A number of localities are mentioned in which the perithecial stage is commonly produced, and there seems to be indicated a direct relationship between the autumnal temperature and rainfall and the development of the perithecia. For the prevention of the destructive spread of the disease, attention to these centers is recommended and the perithecia destroyed as far as possible.

Combined treatment against downy and powdery mildew, L. VERNET (*Prog. Agr. et Vit. (Ed. l'Est)*, 27 (1906), No. 19, p. 557).—For combating these 2 diseases of grapes the author recommends spraying with a 2 per cent solution of Bordeaux mixture, 4 applications to be given the vines, and it is suggested that immediately following the first and third applications the vines be dusted with a mixture of equal parts of sublimed sulphur and

gypsum or sulphate of lime. The addition of the sulphate of lime is said to favor the transformation of the copper hydrate, makes the solutions more adherent, and favors the better distribution of the sulphur.

The pathological respiration of grape leaves attacked by downy mildew, L. PAVARINO (*Atti Ist. Bot. Univ. Pavia*, 2. ser., 11 (1906), p. 16; *abs. in Bot. Centbl.*, 102 (1906), No. 28, pp. 38, 39).—The effect of *Peronospora* on the respiration of grape leaves was studied and found to exert a marked influence on the normal respiration, as well as the intramolecular respiration of the leaves. The normal respiration is greatly accelerated by the downy mildew and the intramolecular respiration is much more active in diseased leaves.

On investigating the presence of ferments in both diseased and normal leaves, the author found that the diseased leaves contained much greater quantities of oxidase than normal and that the same is true for injured leaves or nonparasitic diseases. These oxidases he does not believe are directly produced by the parasites, but are the result of a reaction of the protoplasm of the plant when contiguous to the parasite or to some poisonous substances excreted by the parasites. He believes that the oxidizing ferments which are found in various organs of the grape attacked by *Peronospora* are a cause of the disease of wine known as "casse."

The gooseberry mildew in Europe, its spread and prevention, J. ERIKSSON (*Ztschr. Pflanzenkrankh.*, 16 (1906), No. 2, pp. 83-90, pls. 2, map 1).—An account is given of the occurrence and distribution of the gooseberry mildew (*Spherotheca mors-ura*) in which the author mentions its appearance in different countries and indicates later stations of its occurrence. The life history of the fungus is described and brief suggestions given for its control. A brief bibliography is appended.

Notes on *Gleosporium ribis*, H. KLEBAHN (*Ztschr. Pflanzenkrankh.*, 16 (1906), No. 2, pp. 65-83, pls. 2).—In his studies on some of the imperfect fungi, the author has carried on experiments with *Gleosporium ribis*, and from his investigations he is led to recognize its ascospore stage. This stage he describes as *Pseudopeziza ribis* n. sp., and inoculation experiments have shown that this fungus and the conidial form are related.

Studies on *Gleosporium*, P. VIALA and P. PACOTTET (*Ann. Inst. Nat. Agron.*, 2. ser., 5 (1906), No. 1, pp. 31-83, figs. 42).—Studies are reported on *Gleosporium necriscequum*, the cause of the sycamore anthracnose, in which the yeast-like and cyst reproductive bodies are described.

Notes are also given on some similar bodies observed in *Ascochyta pisi*. A description is included of the cultural changes and methods employed in the investigations.

Notes on leaf blight of sycamore, J. BEAUVÉRIE (*Compt. Rend. Acad. Sci. [Paris]*, 142 (1906), No. 26, pp. 1551-1554).—A description is given of the leaf blight of the sycamore due to *Gleosporium necriscequum* or *Gnomonia veneta*, particular attention being called to its occurrence in nurseries. In some parts of France this fungus has been exceedingly destructive, especially on young seedlings, and preventive treatments are suggested.

Cortinarius as a mycorrhiza-producing fungus, C. H. KAUFFMAN (*Bot. Gaz.*, 42 (1906), No. 3, pp. 208-214, fig. 1).—According to the author, while considerable attention has been paid endotrophic mycorrhiza, the fungi which cause ectotrophic mycorrhiza have not been investigated except in a very few cases. Some investigation is needed to determine the fungi causing mycorrhiza in order to determine some of the problems which have to do with its physiological action.

The author had observed that specimens of *Cortinarius* were constantly found

in limited areas in such close proximity to certain trees that there appeared to be some connection between them, and subsequent examinations showed that a species of *Cortinarius* was associated with red oaks, maples, and climbing bitter sweet (*Celastrus scandens*). This species of fungus, it was observed, is characterized by its brick-red mycelial strands and stem, and microscopical examinations showed that it formed truly ectotrophic mycorrhiza. A discussion is given of the fungus and its relation to the host plants. The species, which has been determined as new, is described under the name *Cortinarius rubripes*.

Studies in root parasitism, C. A. BARBER (*Mem. Dept. Agr. India, Bot. Ser., 1 (1906), No. 1, pp. 30, pls. 7*).—Studies are reported on the root parasitism of the sandalwood tree (*Santalum album*).

Attention has been drawn to the sandalwood tree during recent years on account of the occurrence of a serious disease, and it was thought worth while to make a careful study of the root system with reference to its possible bearing on it. In addition doubt has been cast on the extent of the root parasitism. The author has therefore made a study of the haustoria of the sandalwood tree, paying particular attention to the early stages up to the time when they penetrate the woody tissues of the host plant.

In addition to the parasitic sandalwood, for which over 100 host plants have been found, studies were made of a number of other allied species. The various tissues of the host and its parasite are described at considerable length, and a second paper is promised to deal with the structure of the mature haustorium.

The witch broom disease in Surinam, C. J. J. VAN HALL (*Trop. Life, 2 (1906), No. 6, p. 83*).—The witches' broom disease of cacao is said to be widely spread in Surinam, the disease in places proving a very serious one, inasmuch as it attacks not only the trees, but also the pods. The infested pods exhibit black spots, which spread rapidly, the pods remaining small and deformed. In some cases fully 50 per cent are practically destroyed. Upon the twigs the disease does not seem to be so serious, and the author believes that if the pods can be kept in a healthy condition considerable progress will be made in checking the disease.

To get rid of the disease, experiments are now being carried on in pruning the trees thoroughly, following this by good tillage of the soil, and also spraying with Bordeaux mixture. These experiments have not yet been sufficiently pursued to warrant any definite conclusions, but the indications are that the amount of injury may be decidedly reduced by these treatments.

A fungus attacking the roots of Para rubber, H. N. RIDLEY (*Agr. Bul. Straits and Fed. Malay States, 5 (1906), No. 3, pp. 64, 65*).—The author reports having received from a number of localities rubber trees that were attacked by some fungus which appeared different from *Fomes semitostus*. The specimens were all young trees about 2 in. in diameter, and the roots were encrusted with a white mycelium. The trees were dead; if left alone the trees die within about 3 weeks after the first appearance of the disease. The fungus appears to be some member of the Polyporeae, and the attack quite similar to that which has been noted on clove trees, coffee, etc.

The biology of Polyporus squamosus, A. H. R. BULLER (*Jour. Econ. Biol., 1 (1906), No. 3, pp. 101-138, pls. 5, figs. 6*).—After some general remarks on the destruction of wood by fungi and a review of literature, the author describes his investigations on the destruction of the wood of the sycamore maple by *Polyporus squamosus*.

So far as the author's knowledge goes, this fungus has never been observed on any coniferous tree, but it attacks numerous species of maple, oak, elm,

hazel, walnut, linden, ash, willow, birch, etc. The fruiting bodies of the fungus are described, and it is said that when a tree has been killed by *P. squamosus* the fungus may continue its annual production of fruiting bodies for a considerable period. In this case the fungus is considered saprophytic, and in the case of its appearance on posts, flag poles, etc., it is believed that the infection took place when the trees were living, although under favorable conditions the dead wood might become attacked.

Notes are given on the spore characters of the fungus, experiments on their germination, vegetative growth, etc., after which the changes induced in the wood are described, particular attention being paid to the chemical changes which are brought about by the fungus. Analyses of sound and decayed wood show marked differences in the carbon content, the carbonizing of the wood amounting to an increase of at least 2 per cent of the dry material.

In the study made the author found evidence of the action of enzymes produced by the fungus. Altogether there appeared to be 8 or 10 different enzymes occurring in the fruiting bodies. Among those noted were laccase, tyrosinase, amylase, emulsin, protease, lipase, rennetase, "coagulase," etc.

Attempts were made to develop the fruiting bodies from pure cultures, but while a dense mat of mycelium was secured, no signs of fruiting bodies made their appearance.

The common fungus and insect pests of growing vegetable crops, W. LOCHHEAD and T. D. JARVIS (*Ontario Agr. Col. and Expt. Farm Bul. 150, pp. 34, figs. 35*).—Popular descriptions are given of the diseases of plants which are caused by fungi, slime molds, and insects, and where known the remedies are described. A chapter is given on the preparation and application of fungicides and insecticides.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Distribution and migration of North American ducks, geese, and swans, W. W. COOKE (*U. S. Dept. Agr., Biol. Survey Bul. 26, pp. 90*).—Of the 64 recognized species of ducks, geese, and swans in North America north of Mexico, 24 breed in the United States. Of these the most important species are considered as being wood duck, mallard, black duck, teal, canvasback, red-head, and Canada goose.

The effect of inadequate protection for water fowl is seen most strikingly in the case of the wood duck, which has suffered greatly in some localities. The protection of ducks, geese, and swans in order to be effective must be in force particularly at the breeding season, during migration, and in the winter. The striking diminution in numbers of some of the species is largely due to unsportsmanlike slaughter at times when they are least able to escape.

One of the most important winter homes of North American ducks and geese is the State of California. An elaborate account is presented of the distribution and migration of these species and detailed notes are given on the breeding range, winter range, spring migration, and fall migration of each of the species and subspecies recognized in North America.

The North American eagles and their economic relations, H. C. OBERHOLSER (*U. S. Dept. Agr., Biol. Survey Bul. 27, pp. 31, pls. 2, figs. 2*).—The economic relations of eagles are somewhat difficult to determine on account of the fact that they feed upon many rodents and other noxious small mammals, but also destroy game birds, water fowl, lambs, poultry, and other useful animals. In the author's opinion eagles are therefore to be considered about neutral in economic influence.

A detailed account is given of the general habits, food, and economic status of the golden eagle, gray sea eagle, and bald eagle. In the case of each one of these species its distribution and the extent of its destruction by man are mentioned.

The economic relations of seed crows as based on an examination of stomach contents during a period of 11 years, M. HOLLRUNG (*Landw. Jahrb.*, 35 (1906), No. 4, pp. 579-620, fig. 1).—During the years 1895 to 1905, inclusive, the stomachs of seed crows were examined for the purpose of learning their feeding habits. Many inquiries were made personally and through agricultural newspapers with regard to this question in parts of the Province of Saxony.

The material at the disposal of the author was unusually extensive and a careful examination was made of about 4,000 stomachs of these birds. It appears that the seed crows are omnivorous, feeding upon seeds, animals, various kinds of waste material, and mineral matter. Occasionally the birds are charged with killing young hare and injuring cereals. Barley, oats, rye, wheat, corn, buckwheat, and other vegetable material were found in the stomachs of the seed crows. On the other hand, the birds destroyed cockchafers, wireworms, various caterpillars, and snout beetles which are injurious to cultivated crops. Under ordinary conditions, therefore, it is believed that the destruction of seed crows is not justified.

Birds as conservators of the forest, F. E. L. BEAL (*N. Y. State Forest, Fish and Game Com. Ann. Rpt.*, 8-9 (1902-3), pp. 236-274, pls. 14, figs. 2).—In this article particular attention is given to a discussion of the habits of birds which spend a large part of their time in forest trees. The benefits derived from the destruction of forest insects by these birds are mentioned and notes are also given on the injury caused to trees by a destruction of buds. The birds studied in this connection include woodpeckers, titmice, creepers, warblers, cuckoos, etc.

The squirrels and other rodents of the Adirondacks, F. C. PAULMIER (*N. Y. State Forest, Fish and Game Com. Ann. Rpt.*, 8-9 (1902-3), pp. 335-351, pls. 4).—In the State of New York, 28 species of rodents are recognized. In the present article brief notes are given on the habits of the more conspicuous species with particular reference to their food and economic relations.

Destruction of rats and mice in fields, C. MACÍAS (*Com. Par. Agr. [Mexico]*, *Circ.* 41, pp. 25, figs. 28).—Brief notes are given on the injuries caused by various species of mice to cultivated crops. A number of formulas are given for the preparation of poisoned baits to destroy these pests and suggestions are made regarding a great variety of traps also used for this purpose.

Notes on the destruction of injurious vermin, C. M. JOHNSTON (*Orange River Colony Dept. Agr., Biol. Div. Leaflet 1*, pp. 7).—In eradicating jackals strychnin is the drug which is most commonly used in poisonous baits. At present, however, it is more difficult to induce the jackals to eat the bait than was formerly the case.

Notes are given on the methods of preparing poisonous baits and on the use of traps and other methods for destroying rabbits, baboons, and grain-eating birds.

The frog book, MARY C. DICKERSON (*New York: Doubleday, Page & Co.*, 1906, pp. XVII+253, pls. 112, figs. 35).—The biology and feeding habits of North American spadefoot toads, common toads, tree frogs, and frogs are given together with elaborate descriptions of the appearance of the various species. The economic relations of frogs and toads are discussed and notes are given on the nature of their food. The illustrations of the different species are of unusual excellence.

Third annual report of the State entomologist, R. A. COOLEY (*Montana Sta. Bul.* 62, pp. 181-230, pls. 4, figs. 4).—This report is occupied with a general account of the codling moth, plum gonger, bollworm, and white-lined morning sphinx.

The codling moth is now distributed locally in the main fruit-growing regions of Montana, and the author believes that it can not be exterminated. Recommendations are made of methods calculated to control the insect in infested localities.

The plum gonger has a local distribution in the State at present and attacks only native varieties of plums. During 1905 the bollworm did considerable damage to corn in various parts of the State. Some alarm was felt by alfalfa growers over the unusual prevalence of the white-lined morning sphinx. The author believes, however, that this insect was feeding mostly on weeds and only to a slight extent on cultivated plants.

Report of the chief inspector of nurseries and orchards, A. F. BURGESS (*Ohio Dept. Agr., Div. Nursery and Orchard Insp. Rpt.* 1905, pp. 45).—The author discusses the extent of nursery inspection during the year, the number of trees infested with San José scale and other injurious pests, fumigation of nursery stock, orchard inspection, and other routine work of the inspector's office. An account is also presented of cankerworm, plum curculio, codling moth, grape-berry moth, elm-leaf beetle, catalpa sphinx, and other injurious insects. Brief notes are given on methods of spraying for various insect pests and on the use of K-L mixtures, Con-Sol, and other insecticides.

The monthly bulletin of the division of zoology, H. A. SURFACE (*Penn. Dept. Agr., Mo. Bul. Div. Zool., 4* (1906), No. 1, pp. 40, figs. 2).—Notes are given on experiments with asparagus beetles. Spraying with lead arsenate and resin soap gave good results. A list is also presented, with formulas, for the preparation of standard insecticides and fungicides, together with notes on the special treatment of a number of the more common injurious insects.

The monthly bulletin of the division of zoology, H. A. SURFACE (*Penn. Dept. Agr., Mo. Bul. Div. Zool., 4* (1906), No. 2, pp. 43-80, pls. 9).—A brief account is given of the use of whale-oil soap, kerosene emulsion, and lime-and-sulphur wash in combating the oyster-shell scale, scurfy scale, and San José scale. The greater part of the bulletin is occupied by a systematic description of Hemiptera.

The monthly bulletin of the division of zoology, H. A. SURFACE (*Penn. Dept. Agr., Mo. Bul. Div. Zool., 4* (1906), No. 3, pp. 82-112, pls. 4).—In experiments with insecticides for controlling oyster-shell bark-louse good results were obtained with whale-oil soap and kerosene emulsion. Notes are given on summer treatment of scale insects, ants, fall webworms, flies, red spiders, grain weevil, and other insect pests.

Index-catalogue of medical and veterinary zoology, C. W. STILES and A. HASSALL (*U. S. Dept. Agr., Bur. Anim. Indus. Bul.* 39, pts. 14, pp. 951-1044; 15, pp. 1045-1116; 16, pp. 1117-1208).—In continuation of the index of medical and veterinary zoology these parts contain the names of authors from Laache to Lyutkevich.

Report of the secretary of the Louisiana crop pest commission, 1904-5, W. NEWELL (*Crop Pest Com. La. Circ.* 7, pp. 27).—Brief statements are presented regarding boll-weevil quarantine in Louisiana, experiments with cultural methods, Paris green, and other means of controlling the boll weevil, together with notes on the San José scale, nursery and orchard inspection, cattle ticks, horseflies, and orange insects.

Injurious insects and other animals observed in Ireland during the year

1905, G. H. CARPENTER (*Econ. Proc. Roy. Dublin Soc.*, 1 (1906), No. 8, pp. 321-344, pls. 5, figs. 8).—Notes are given on nematode worms, cabbage aphid, diamond-back moth, slugs, gooseberry sawfly, wireworms, rice weevil, and various other insects affecting cultivated crops and trees.

In combating slugs, dressings of salt or lime have usually been found most effective. The cabbage aphid may be controlled in small gardens by spraying with kerosene emulsion. Attention is called to the importance of attacking this insect at its earliest appearance.

Entomological inspection report, A. CRAW (*Hawaii. Forester and Agr.*, 3 (1906), No. 6, pp. 187-189).—A brief account is given of the extent of importation of fruits, vegetables, and various plants and of the inspection made on such material. During this inspection of more than 19,000 packages, many cases of serious infestation were discovered, and infested plants or fruits were fumigated or destroyed.

Notes on insect swarms on mountain tops in New Zealand, G. V. HUDSON (*Trans. and Proc. New Zeal. Inst.*, 38 (1905), pp. 334-336).—Some of the commonest species of insects in New Zealand were observed in large swarms on mountain tops at elevations of 4,000 to 7,200 ft. In some cases ladybirds were noticed in immense quantities at high elevations where there is no vegetation and where plant lice could hardly have been present to serve as food.

Seasonable notes on some orchard pests, G. QUINN (*Jour. Dept. Agr. So. Aust.*, 10 (1906), No. 1, pp. 9-14).—Biological and economic notes are given on the codling moth, oyster-shell bark-louse, black peach aphid, plum curculio, peach leaf curl, and apple scab.

The entomological section, C. B. SIMPSON (*Transvaal Agr. Jour.*, 4 (1906), No. 16, pp. 839-853, pl. 1, fig. 1).—The life history and nest-building habits of white ants are described. In destroying these insects the best results have been obtained from the use of an apparatus by means of which fumes from a heated mixture containing 1 part sulphur and 9 parts arsenic are pumped directly into the nest. A brief statement is also made regarding locust control.

Report of the government entomologist for the half year ended Dec. 31, 1904, C. P. LOUNSBURY (*Cape Good Hope Dept. Agr., Rpt. Govt. Ent. 1904, pt. 2, pp. 12*).—During the period under report particular attention was given to experiments with dips for the destruction of ticks, investigation of grape diseases, and the regulation of the importation of plants. Arsenite of soda was found to possess great value as a tick destroyer. This remedy was tested on a number of farms and was found to be as efficient without the addition of tar as when this material was added. C. W. Mally also presents a brief report on locust destruction, fruit fly, and cornstalk borer.

Report of the government entomologist for the year 1905, C. P. LOUNSBURY (*Cape Good Hope Dept. Agr., Rpt. Govt. Ent. 1905, pp. 95-104*).—The work of the year was concerned largely with a study of the transmission of animal diseases by ticks, the natural enemies of the fruit fly, cornstalk borer, locust destruction, codling moth, and nursery inspection. Little hope is expressed for the successful control of the fruit fly or codling moth by means of insects. Considerable attention is now being given to the establishment of Capri figs in Cape Colony for the purpose of introducing the fig wasp, which will assist in fertilizing Smyrna figs.

Some notable instances of the distribution of injurious insects by artificial means, F. V. THEOBALD (*Sci. Prog. Twentieth Cent.*, 1 (1906), No. 1, pp. 58-72, figs. 3).—A large number of examples are mentioned of injurious insects which have been carried from their original home to other parts of the same country or other countries in food products or as a result of the extensive

development of international commerce. In this connection particular mention is made of the codling moth, fruit flies, scale insects, woolly aphis, pear midge, Colorado potato beetle, Hessian fly, and sheep scab mite.

Cold storage as a factor in the spread of insect pests. C. FULLER (*Natal Agr. Jour. and Min. Rec.*, 9 (1906), No. 7, p. 656).—The author had occasion to observe that the fruit-fly maggots may remain alive in peaches kept in cold storage at a temperature of 39° to 40° F. for a period of at least 121 days.

Report of the economic zoologist on cotton insects, L. ICHES (*Bol. Min. Agr. [Buenos Ayres]*, 5 (1906), No. 3, pp. 273-320).—The author made a study of the insect pests of cotton in Chaco, particular attention being given to *Prodenia ornithogalli* and *Aelia xyliua*. In combating the lepidopterous pests of cotton good success was had from the use of Paris green or arsenic in the proportion of 1 part to 50 parts of flour. Paris green as well as white arsenic was also used in a fluid form.

The boll weevil. Information concerning its life history and habits, W. NEWELL (*Crop Pest Com. La. Circ.* 9, pp. 29, figs. 15).—A summary is presented of the life history and habits of the boll weevil in its different stages and the means by which it is disseminated, its migration, hibernation, and other matters connected with an understanding of its history.

Report of the executive committee upon the Paris green experiments conducted against the boll weevil during 1905, B. W. MARSTON, L. S. FRIERSON, and W. NEWELL, (*Crop Pest Com. La. Circ.* 8, pp. 31, figs. 4).—A test was made of Paris green as a means of controlling the cotton-boll weevil. This remedy was applied to cotton kept under large wire-screen cages and under field conditions.

The season was unfavorable to the work on account of the late development of cotton and other difficulties met with in applying Paris green at the most effective period. When Paris green was applied at the rate of 10 $\frac{3}{4}$ lbs. per acre in 4 applications nearly all of the boll weevils were destroyed, and the insects were greatly reduced in number by the use of 2 $\frac{3}{4}$ lbs. of Paris green per acre. The use of the large quantity of Paris green resulted in considerable injury to the cotton and a diminished yield.

The general conclusion reached from this series of experiments is that Paris green may be applied to cotton that is blooming and squaring in such a way as to reduce the number of boll weevils, but the injury to cotton is quite serious. It is suggested that during average seasons better results may be obtained since Paris green could be applied earlier.

The tobacco splitworm, an enemy of tomato, eggplant, and poha in Hawaii, J. KOTINSKY (*Hawaii. Forester and Agr.*, 3 (1906), No. 7, pp. 200, 201).—*Phthorimaea operculella* is reported as causing considerable injury to tomatoes, eggplants, and the cape gooseberry in Hawaii. A number of parasites are known to prey upon this pest. The artificial remedies suggested by the author include clean cultivation, the removal of all rubbish from cultivated fields, and careful attention to the fertility of the soil.

An outbreak of locusts, A. C. TONNELIER (*Bol. Min. Agr. [Buenos Ayres]*, 5 (1906), No. 3, pp. 328-356, figs. 33).—The injuries caused by large swarms of locusts are described and notes are given on practical remedies for combating them. These include the use of barriers and driving by means of brooms and branches.

The locust mite, T. D. JARVIS (*Canad. Ent.*, 38 (1906), No. 10, pp. 349, 350, figs. 2).—*Trombidium locustarum* was very common during the season, especially on the red-legged locust. A brief account is given of the appearance and habits of this parasite.

Cicadula sexnotata and its control, J. R. JUNGNER (*Arb. Deut. Landw. Gesell.*, 1906, No. 115, pp. 50, pl. 1, figs. 3, dgm. 1).—This insect is well known throughout Germany as the cause of great injury to grasses, cereals, and certain legumes.

The habits and life history of the species are described in considerable detail. According to the author, a number of other insects are associated with it in attacking cultivated crops, and parasitic fungi in some cases become located on the plants as a result of its attacks. A number of insects and birds prey upon *Cicadula sexnotata*, but the insect is not sufficiently controlled by natural means.

In combating the pest, fields of grain may be protected by plowing furrows around them in which running water is maintained or which are covered with a film of oil. Badly infested grass lands may be burned over in the fall, and considerable benefit is derived from suitable systems of rotation.

Hairy caterpillar pests of crops, H. MAXWELL LEFROY (*Agr. Jour. India*, 1 (1906), No. 3, pp. 187-191, pl. 1).—The habits and life history of a number of caterpillars in India are briefly outlined. Attention is called to the desirability of recognizing all such pests in the early stages, since insecticides applied at this time are far more effective.

Hyponomeuta malinella, L. DASSONVILLE (*Bul. Agr. Algérie et Tunisie*, 12 (1906), No. 14, pp. 298-300, fig. 1).—The caterpillar of this insect is one of the most serious pests of apple trees in the region of Ain-Touta, but experiments have shown that it may be readily controlled by the use of arsenate of lead. Directions are given for preparing this insecticide.

Pear and cherry-tree slug, L. J. NEWMAN (*Jour. Dept. Agr. West. Aust.*, 14 (1906), No. 2, pp. 109-111, fig. 1).—The habits and life history of this pest are briefly described. As remedies in controlling the insect the author suggests dry air-slaked lime, white hellebore, Paris green, kerosene emulsion, benzole, and Bordeaux mixture.

Important notes on the gypsy and brown-tail moths, A. E. STENE (*Off. Comr. Suppression Gypsy and Brown-tail Moths [R. I.]*, Circ. 1, pp. 14, pls. 4).—A copy is given of the recent Rhode Island law regarding the extermination of these pests and providing for the appointment of a commissioner to have charge of the work. Brief notes are given on the life history of the pests and on methods for controlling them.

The gypsy and brown-tail moths, E. P. FELT (*N. Y. State Mus. Bul.* 103, pp. 42, pls. 10).—On account of the unusual interest manifested at present in the control of the gypsy and brown-tail moths, the author presents a general account of the appearance, habits, life history, and most effective means of combating these pests.

The fruit fly and its parasites, A. HEMPEL (*Bol. Agr. [São Paulo]*, 7, ser., 1906, No. 5, pp. 206-214).—A brief historical statement is given concerning the investigations conducted by various entomologists in the neighborhood of Bahia in search of parasites of *Ceratitis capitata*. A number of such parasites have been found and have been kept under the observation of the author for the purpose of determining their economic importance.

As a result of this study it is concluded that parasites can not be depended upon to furnish much assistance in controlling the pest, and fruit growers are urged to continue the usual methods of control.

The spread of the fruit fly (*Ceratitis capitata*) in the neighborhood of Paris, A. GIARD (*Compt. Rend. Acad. Sci. [Paris]*, 143 (1906), No. 8, pp. 353, 354).—The author called attention to the presence of the fruit fly about Paris six years ago, but little effort has been put forth to control this pest. In the meantime it has gradually increased and is doing considerable damage.

The orange-tree butterfly, C. W. HOWARD (*Transvaal Agr. Jour.*, 4 (1906), No. 16, pp. 727-732, pl. 1).—The appearance and life history of *Papilio demoleus* are briefly outlined. This pest may be controlled by spraying with Paris green at the rate of 1 lb. to 200 gal. of water.

Internal parasites of *Diaspis pentagona*, A. BERLESE (*Bol. Uffic. Min. Agr., Indus. e Com.* [Rome], 4 (1906), No. 7, pp. 663, 664).—*Diaspis pentagona* is recognized as a serious pest of mulberries, and some attention is being given to the encouragement of parasites of this insect.

On the parasites of *Diaspis pentagona*, L. O. HOWARD (*Ent. News*, 17 (1906), No. 8, pp. 291-293, fig. 1).—*D. pentagona* has been known in the District of Columbia since 1892, and an opportunity has, therefore, been had to study rather closely its insect parasites. A number of infested scale have been sent to Italy in the hope that beneficial parasites might be reared from them to assist in combating the pest in that country. A considerable number of parasites have been reared, one of which is described as new under the name *Prospalta berlesci*.

The mango weevil (*Cryptorhynchus mangiferæ*), D. L. VAN DINE (*Hawaii Sta. Press Bul.* 17, pp. 11, pls. 2).—The injury done by the mango weevil to the seeds of mangoes was first noted last year and the pest has already become a serious one. Apparently it has been introduced into Hawaii some time since 1898.

The habits and life history of the pest are briefly described. The weevil undergoes its entire development within the seed and can not, therefore, be treated by ordinary insecticides. It is stated that the destruction of rubbish about the trees during the period from October to March will kill many of the hibernating weevils. It is also recommended that neglected trees along the wayside be destroyed.

The oyster-shell bark-louse, G. QUINN (*Jour. Dept. Agr. So. Aust.*, 8 (1905), No. 11, pp. 639-647, figs. 3).—It is not known when the oyster-shell bark-louse was first introduced into South Australia, but apparently it has been present for many years. A detailed account is given of the life history of this insect and the injuries which it produces.

In spraying for the pest the author recommends the use of lime-sulphur-salt wash, various resin compounds, kerosene emulsion, and red oil emulsion. The last-named insecticide is made of 1 lb. soap, 1 gal. red oil, and 1 gal. soft water, the mixture being diluted before spraying to 14 to 16 gal.

The oyster-shell bark-louse, T. D. JARVIS (*Canad. Ent.*, 38 (1906), No. 9, pp. 289-294, figs. 3).—The appearance, habits, and life history of this insect are briefly discussed by way of comparison with scurfy scale and San José scale. While a number of efficient remedies are known for this pest, the best results have followed the use of lime-sulphur-salt wash.

A new species of fungus parasitic on *Ceroplastes rusci*, A. BERLESE (*Redia*, 6 (1906), No. 41, pp. 166-168).—In western Africa, particularly in Dahomey, a scale insect was observed in large numbers on the coconut palm which proved to be *Aspidiotus destructor*. A mixture containing soda and resin is recommended as a spray for this pest.

A new species of fungus parasitic on *ceroplastes rusci*, A. BERLESE (*Redia*, 3 (1905), No. 1, pp. 8-15, pl. 1, figs. 3).—In the body cavity and various organs of a number of scale insects, including *Ceroplastes rusci*, fungus bodies are found resembling yeast cells. The fungus is described as new under the name *Oospora saccardiana*.

Ladybirds and woolly aphis, D. L. BREEN (*Jour. Dept. Agr. West. Aust.*, 13 (1906), No. 5, p. 447).—*Leis conformis* was introduced from Tasmania and

liberated in apple orchards badly infested with woolly aphid. The ladybird in question has shown itself to be very efficient, having practically annihilated the woolly aphid on the majority of the apple trees. A number of native ladybirds are beneficial.

The mite disease of grapevines, H. MÜLLER-THURGAU (*Centbl. Bakt. [etc.]*, 2. *Abt.*, 15 (1905), No. 19-20, pp. 623-629, figs. 2).—The disease caused by this mite was at first not understood. Since the discovery of the mite, however, successful remedies have been devised. The remedies suggested by the author include spraying with a 4 per cent solution of lysol, a 3 per cent solution of soda, or a 1 per cent solution of carbolic acid. Badly infested parts may be removed and destroyed.

Winter treatment for acariosis of grapes, H. FAES (*Chron. Agr. Vaud*, 19 (1906), No. 3, pp. 43-49, pl. 1).—Lysol in 4 per cent solution gave excellent results in laboratory tests. It moistened the wood instantly and penetrated into all cracks, killing the mites promptly. A mixture containing 3 per cent black soap and 1 per cent carbolic acid gave results about equal to those obtained with lysol. A 30 per cent solution of iron to which 1 per cent sulphuric acid was added was effective in destroying the mites, but did not spread so readily as lysol.

Margorodes vitium, J. M. HUERGO (*Bol. Min. Agr. [Buenos Ayres]*, 5 (1906), No. 3, pp. 321-325).—This insect causes great damage to grapes, but in some cases it appears that the injury attributed to it has been caused by nematode root worms and other diseases.

The insects affecting the black locust and hardy catalpa, E. C. COTTON (*Ohio Dept. Agr., Div. Nursery and Orchard Insp. Bul.* 7, pp. 55, figs. 11).—On account of the increased demand for black locust as railroad ties and for similar purposes, the study of its insect pests assumes considerable importance. This tree is seriously attacked by a number of pests, the most important of which is the locust borer. The insect injury is exceedingly serious, particularly on account of the fact that it is not readily detected in the early stages of attack. Detailed notes are given on the habits, life history, and injuries caused by the locust borer, locust carpenter moth, *Odontota dorsalis*, *Ecdytophaga insiticiaria*, *Crepidodera rufipes*, *Apion nigrum*, locust sawfly, San José scale, Cecropia moth, and numerous other species which injure the locust more or less.

The hardy catalpa is much less seriously attacked by insect pests. The author discusses the more serious of these enemies, including *Ceratonia catalpa*, *Cecidomyia catalpa*, fall webworm, white grubs, and other insects.

Elm-leaf beetle, V. MAYET (*Prog. Agr. et Vit. (Ed. l'Est)*, 27 (1906), No. 25, pp. 725-728, pl. 1).—An account is given of the habits, natural enemies, and means of combating this pest. A large number of insects prey upon it, but these are not sufficient to hold it in check. Spraying with arsenicals is a satisfactory treatment.

Injuries to trees by insects, G. CECCONI (*Staz. Sper. Agr. Ital.*, 38 (1905), No. 10-12, pp. 865-905, pls. 7).—Particular attention is given in this article to an account of the life history, habits, and injurious attacks of white ants and various species of moths, beetles, and other insects which injure forest trees.

Two enemies of *Juniperus communis*, V. TORKA (*Naturw. Ztschr. Land u. Forstw.*, 4 (1906), No. 9, pp. 399-404, figs. 5).—While the common cedar is not considered of much value in Germany, it has nevertheless been found necessary to devote some attention to its insect enemies. The author presents notes on the habits, life history, and injurious attacks of *Phlaosinus thujae* and *Callidium castaneum*.

A note on the life history of *Hoplocerambyx spinicornis*, E. P. STEBBING

(Calcutta: Supl. Govt. Printing, India, 1906, pp. 16, pls. 3).—Sal trees are largely used for railroad ties in India, and this wood has been so badly injured by the attacks of *H. spinicornis* that large quantities of ties have had to be rejected. The full-grown larvæ are found in the wood in February and the beetles appear and are seen on the wing from May until July. The tunnels of the larvæ penetrate into the heart of the tree. The only way of combating the pest successfully appears to be the drastic method of cutting out infested trees and charring the outside so as to kill all larvæ.

Synopsis of Portuguese galls and gall insects, J. S. TAVARES (*Brotéria*, 4 (1905), pp. V-VII + 1-123, pls. 14).—A brief bibliography relating to the galls of Portugal is presented and an elaborate tabulation is given of the gall insects found upon various trees and herbaceous plants in Portugal.

Studies on South American termites, N. HOLMGREN (*Zool. Jahrb., Abt. System., Geogr. u. Biol. Tiere*, 23 (1906), No. 5, pp. 521-676, figs. 81).—A detailed descriptive account is presented of various species of white ants known to occur in South America. Many of these species are described as new.

Notes are given on the biology of white ants with special reference to the forms of the individuals and the construction of their nests. A bibliography of the subject is also presented.

Habits and peculiarities of some South African ticks, C. P. LOUNSBURY (*Cape Town: Govt., 1905, pp. 10*).—A number of ticks are known to cause serious injury to farm animals in Cape Colony, aside from their agency in carrying diseases. The author has given particular attention in his investigations to *Amblyomma hebraeum*, *Argas persicus*, *Ixodes pilosus*, and various species of *Rhipicephalus* and *Boophilus*. Attention is called to the fact that our knowledge of the life history of ticks is very meager. The author reared the different species through as many stages as possible and presents data as to the time occupied by the ticks in different stages, and other details of their life history.

A new enemy of common fowls, A. HEMPEL, (*Bol. Agr. [São Paulo]* 7, ser., 1906, No. 6, pp. 259-261).—*Argas reflexus* is known to be a parasite on pigeons and the author has observed a number of instances in which young chickens and adult fowls were infested by it. The remedies usually adopted against *A. persicus* will doubtless be of avail against this pest.

Studies on Culex and Anopheles, B. GALLI-VALERIO and JEANNE ROCHAZ-DE JONGH (*Atti Soc. Studi Malaria*, 7 (1906), pp. 1-17).—The author presents in a tabular form data relating to the time of appearance of various species of mosquitoes and the temperature and other climatic conditions which prevailed.

In a study of the natural enemies of mosquitoes it was found that *Triton cristatus* and *T. muticellus* are quite influential in the destruction of the mosquito larvæ and nymphs. Further studies were made with reference to the action of the spores of *Aspergillus niger* and *A. glaucus* on mosquitoes. *A. niger* was found to exercise a very prejudicial effect on the development of mosquitoes and in general the presence of the spores of these fungi in water infested with mosquito larvæ is believed to check their multiplication to an appreciable extent.

A new mosquito killer (*Municipal Jour. and Engin.*, 21 (1906), No. 14, pp. 335, 336).—A by-product obtained in the manufacture of turpentine by the fractional distillation of pine wood has been tested in the destruction of mosquitoes and has been found to be very effective, possessing certain advantages over sulphur. The material is a liquid which can be readily volatilized by the application of heat and a current of air over the heated surface. The fumes are, therefore, generated outside of the room to be fumigated and then conducted into

this room. The material costs about the same as sulphur, requires only 1 hour for treatment as compared with 2 hours with sulphur, does not injure metals, fabrics, paint, or color, and is not particularly irritating or harmful to human beings.

Mites affecting farm homesteads, T. D. JARVIS (*Canad. Ent.*, 38 (1906), No. 7, pp. 239-241).—A description is given of a serious infestation of a house with *Tyroglyphus longior*. The mites occurred in large numbers and collected on clothing and other articles. The house was tightly closed and fumigated with hydrocyanic-acid gas, using 24 oz. of cyanid to 1,000 cu. ft. The treatment proved quite effective and apparently destroyed all of the mites.

Cockroaches, W. W. FROGGATT (*Agr. Gaz. N. S. Wales*, 17 (1906), No. 5, pp. 440-447, pl. 1).—The author describes several of the common species of cockroaches in New South Wales and presents a brief account of practical methods for controlling the pest. The methods include the use of phosphorus paste, borax, gunpowder, bisulphid of carbon, and hydrocyanic acid.

The reaction of insects toward formalin fumes, K. LAMPERT (*Ztschr. Wiss. Insektenbiol.*, 2 (1906), No. 1, pp. 12, 13).—On the occasion of fumigating a house after an outbreak of scarlet fever the author placed a number of insects in open glass vessels and other situations to note the influence of formalin fumes upon them. The fumigation was prolonged for 4 hours. The insects used in this experiment were cockroaches, spiders, larvæ of wasps, etc. None of the insects were affected by the formalin fumes. The author believes, therefore, that formalin is not adapted for the destruction of insects in houses.

Destruction of insects in greenhouses by hydrocyanic acid, L. TILLIER (*Jour. Agr. Prat., n. ser.*, 12 (1906), No. 32, pp. 181, 182, fig. 1).—The use of hydrocyanic acid in destroying insects in greenhouses is becoming more generally practiced in France. For this purpose a special apparatus is illustrated and recommended. For ordinary greenhouse work the author suggests the use of 2.5 gm. of potassium cyanid for a cubic meter of space.

Arsenate of lead, C. P. LOUNSBURY (*Agr. Jour. Cape Good Hope*, 29 (1906), No. 2, pp. 223-228).—The author states that arrangements have finally been made by which an excellent quality of arsenate of lead may be obtained in Cape Colony. This insecticide is recommended as superior to Paris green or any other arsenical poison for use against the codling moth and most leaf-eating insects.

Spraying to control or prevent injury from insects and plant diseases, R. I. SMITH (*Ga. Bd. Ent. Bul.* 19, pp. 127-168, figs. 3).—A general statement is given regarding the importance of spraying and the use of insecticides and fungicides.

The main part of the bulletin is occupied with formulas for preparing and directions for applying a standard insecticide and fungicide. A spray calendar is also given recommending applications for the more common injurious insects and fungus diseases.

Apiculture, R. HOMMELL (*Apiculture. Paris: J. B. Baillière & Son*, 1906, pp. XII+542, figs. 178).—This volume is one of a series which will constitute an agricultural encyclopedia published under the direction of G. Wery. The whole subject of bee raising is discussed in detail. The subject-matter of the volume is arranged under the following heads: Anatomy and physiology of bees, biology of bee colonies, wax, nectar, honey, bee plants, structure of beehives, management of bees, extraction of honey, utilization of all bee products, and the various enemies of bees.

Bees and the corolla of flowers, F. FAIDEAU (*Apiculteur*, 50 (1906), Nos. 3, pp. 98-107, figs. 5; 5-6, pp. 195-203, figs. 5).—A study was made of the

influence exerted by the color and odor of flowers upon the visits of bees in the collection of honey and other bee foods. The author comes to the conclusion, as the result of this observation, that the odor of flowers is a much more important factor in attracting bees than is the color or shape of the corolla.

FOODS—HUMAN NUTRITION.

Concerning the behavior in the body of certain organic and inorganic phosphorus compounds, F. W. TUNNICLIFFE. (*Arch. Internat. Pharmacod. et Théor.*, 16 (1906), No. 1-4, pp. 207-220).—Using 2 children as subjects, a comparison was made of an organic phosphorus body (a compound of glycerophosphoric acid and pure casein) and an inorganic body, calcium phosphate, the special object of the experiments being to determine whether by increasing the phosphorus of the diet it is possible to increase the amount of phosphorus retained in the body and to observe the effects of inorganic and organic phosphorus compounds upon proteid metabolism.

The balance of income and outgo of nitrogen was determined in the experimental periods and in the fore and after periods. The conclusions which were drawn are, in effect, as follows:

In the healthy child the addition of an organic phosphorus compound to the diet was followed by an increase in the amount of phosphorus assimilated by and retained in the body. An organic phosphorus compound increases the amount of nitrogen of the food assimilated. The addition of calcium phosphate to the food did not increase the amount of phosphorus assimilated or retained by the child, nor did this compound exert any favorable influence upon the assimilation of the nitrogen of the food. The phosphorus contained in the sodium glycerophosphate of casein is practically entirely assimilated by the body.

The article contains a summary and discussion of data regarding the more or less complicated organic phosphorus compounds which are regarded partly as foods and partly as medicines which "have found extensive therapeutic use and seem to be gradually replacing the older inorganic phosphates."

The value of experiments on the metabolism of protein, E. ABDERHALDEN (*Zentbl. Gesam. Physiol. u. Path. Stoffwechsls. u. ser.*, 1 (1906), No. 18, pp. 561-565).—A critical discussion of recent studies of proteids. The author believes that a knowledge of cell metabolism may be gained by biological and chemical methods.

Progress of proteid cleavage on different diets, H. VOGT (*Beitr. Chem. Physiol. u. Path.*, 8 (1906), No. 11-12, pp. 409-430, figs. 5).—Studies with men and dogs, in most of which the proportion of nitrogen and phosphoric acid in the urine was determined at hourly intervals after the ingestion of food, showed that the rate of digestion varied with different proteids.

The author points out that when the cleavage curves of different foods and combinations are known, together with the factors dependent upon them, some satisfactory theories can be formulated regarding diet in health and especially in disease.

Proteid substances in muscle, M. SOAVE (*Atti R. Acad. Sci. Torino*, 40, No. 13, p. 831; *abs. in Zentbl. Physiol.*, 20 (1906), No. 12, p. 394).—Analyses showed that beef muscle and rabbit muscle contained about the same proportions each of histidin, arginin, and lysin. Quite different proportions were found in myosin and myogen. Ammonia nitrogen was also found in myogen but not in myosin. According to the author, at least one of the hexon bases, namely arginin, must exist in muscle in a free state or at all events in a compound which is not an integral part of the muscle proteid.

The present knowledge regarding fat considered from a physiological-chemical standpoint, A. JOLLES (*Umschau*, 10 (1906), No. 40, pp. 795, 796).—A summary of data regarding the structure of fat, its cleavage in the body, forms in which fat is assimilated, lecithin and its compounds, and similar topics. The author points out that fat is excreted in the human body through the skin, the urine, and the feces, and that the total amount excreted per week varies according to the individual, the temperature of the atmosphere, the work performed, and other factors, for instance, being greater when severe work is performed in a warm temperature than when the temperature is cool and no work is performed.

Mercers' Company lectures on recent advances in the physiology of digestion, E. H. STARLING (*London: Archibald Constable & Co., Ltd.*, 1906, pp. 156; *rev. in Brit. Med. Jour.*, 1906, No. 2387, pp. 781, 782).—The work of other investigators has been included in this general summary, as well as that of the author and his collaborators.

Some of the questions considered are the changes which food stuffs undergo in the process of digestion, the rate of change, the factors which cause cleavage to cease, digestive ferments, and the mechanism of the movements of different parts of the digestive tract.

Influence of chocolate and coffee on uric acid, P. FAUVEL (*Compt. Rend. Acad. Sci. [Paris]*, 142 (1906), No. 25, pp. 1428-1430).—The excretion of purin bases in the urine was increased by the methyl xanthins of chocolate and coffee, while the uric acid excretion was unchanged. The precipitation of uric acid by acids was prevented. In the author's opinion, the influence of the bodies present in chocolate and coffee, especially theobromin, is less pernicious than that exerted by the purin bodies of meat and leguminous vegetables.

Notes on purin-free diets, W. A. POTTS (*Lancet [London]*, 1906, II, No. 14, pp. 933-936, fig. 1).—Basing his argument on the contention that it is desirable for persons in health, as well as those suffering from various diseases, to subsist on a purin-free diet, different foods and food combinations are discussed, and some arguments are presented for a fruitarian diet. The so-called nutritive value of a number of foods is shown graphically, but apparently the data represent simply total dry matter.

Sailors' food, W. SPOONER (*Brit. Med. Jour.*, 1906, No. 2388, pp. 862-864).—Information is summarized regarding the rations provided for British sailors, the disadvantages of the usual ration pointed out, and changes suggested. To secure needed variety the use of various simple foodstuffs from time to time is recommended, and a table is given showing quantities which are considered equivalent.

Vegetarianism (*Dietet. and Hyg. Gaz.*, 22 (1906), No. 9, pp. 535, 536).—Some popular fallacies regarding vegetarian diet are pointed out.

As regards the possible transmission of disease from animal and vegetable foods, the following statement is made: "If meats are well cooked and vegetables carefully cleaned, the dangers from disease-producing bacteria will be reduced to a minimum."

A new variety of bread (*Pure Products*, 2 (1906), No. 7, pp. 383-386).—A form of bread made in Europe is described in which the clean moistened grain is allowed to malt until germination begins, then crushed and ground until it is fine, and made into dough. Both rye and wheat are used for this sort of bread.

The solanin content of potatoes, M. WINTGEN (*Arch. Pharm.*, 244 (1906), No. 5, pp. 360-372).—From the author's investigations the conclusion was reached that the solanin content of potatoes varies markedly with different

varieties, but in general is lower than the average figures ordinarily quoted. No increase in the solanin content of stored potatoes was noted when the sprouts were removed. It was found that diseased potatoes possessed no higher solanin content than sound potatoes, nor did it appear that bacteria increased the solanin content.

A biological method of separating cassava starch, E. DE KRUIFF (*Teyssmannia*, 17 (1906), No. 8, pp. 503-508).—In comparative tests the author found that it was possible to obtain a larger yield of cassava starch by biological than by mechanical methods. The biological method consisted in allowing bacteria to destroy the cell walls and free the starch.

The amount of iron in spinach, H. SERGER (*Pharm. Ztg.*, 51 (1906), No. 33, p. 372).—Four samples of spinach containing from 86.7 to 89.5 per cent water showed on an average 0.104 per cent iron on the dry-matter basis. The proportion of iron in alcohol extract of spinach and related topics was also studied.

Candle-nut oil (*Agr. Gaz. N. S. Wales*, 17 (1906), No. 8, pp. 859, 860).—An analysis of candle-nut, the fruit of *Alcurites triloba*, is reported. The proportion of fat is 59.93 per cent. In the author's opinion 55 per cent of the oil could be readily extracted commercially.

The nutritive value of fish, G. ROSENFELD (*Zentbl. Inn. Med.*, 27 (1906), No. 7, pp. 169-176).—From the standpoint of both nutritive value and palatability fish is an important food and in the author's opinion, based on experiments, equal to beef as a source of energy in the diet. It produces the same sensation of satiety and this lasts for a long time. Fish causes the excretion of a smaller amount of uric acid than meat.

Loss of material when fish is cooked, A. BEYTHIEN (*Pharm. Centralhalle*, 47 (1906), p. 140; *abs. in Zentbl. Gesam. Physiol. u. Path. Stoffwechsels, u. scr.*, 1 (1906), No. 17, p. 560).—The experiments reported showed that the water in which fish was boiled contained 8.8 to 11.3 per cent of the total fish protein. As the water could not be used for food purposes on account of its odor this represents a waste.

A cook book for nurses, SARAH C. HILL (*Boston: Whitcomb & Barrows*, 1906; *rev. in Dietet. and Hyg. Gaz.*, 22 (1906), No. 9, p. 576).—The author has brought together recipes of dishes identical in method of cooking and differing only in one or two ingredients, and discusses such topics as fluid diet, light soft diet, convalescent diet, and diets suited to a number of special diseases.

Foods and food control, W. D. BIGELOW and C. H. GREATHOUSE (*U. S. Dept. Agr., Bur. Chem. Bul.* 69, *rev. ed.*, pt. 9, pp. VI + 705-778).—A digest which serves as an index of the compilations of laws regarding food and food control previously noted (*E. S. R.*, 17, p. 891).

Food adulteration, F. W. TRAPHAGEN (*Montana Sta. Bul.* 61, pp. 135-180).—Information regarding the effects of food preservatives and similar questions is summarized and the results of the examination of a number of samples of catsups, jams, jellies, canned goods, and other foods and food products reported. Of the samples examined 101 were found to be adulterated as compared with 143 in which no adulteration was found.

A warning regarding the use of chemical preservatives in meats, E. F. LADD (*North Dakota Sta. Spec. Bul.* 2, pp. 7).—The requirements of the State pure-food law with respect to meat and meat products are pointed out, and attention is directed to the fact that the laws are to be strictly enforced. Data are also reported regarding the examination of a sample of strained honey and 3 samples of preserves, all of which were adulterated or sophisticated.

Preservatives in food and food examination, J. C. THRESH and A. E.

PORTER (*London: J. & A. Churchill, 1906, pp. 484; rev. in Pub. Health [London], 19 (1906), No. 1, pp. 53, 54*).—This volume contains chapters on preservatives, artificial coloring matters, unsound food, the sophistication of food and its detection, and related questions.

Review of the literature of composition, analysis, and adulteration of foods for the year 1905, A. J. J. VANDEVELDE and M. HENSEVAL (*Separate from Bul. Serv. Surveill. Fabric. et Com. Denrées Aliment., 1906, pp. 120*).—The subjects included are general articles, apparatus, water, milk and cream, fats and oils, cheese, cereals and cereal products, spices, sugar, sirup, etc., vinegar, fruits and vegetables, adulteration, and similar topics. In many cases the bibliographical data are supplemented by short abstracts. For earlier work see E. S. R., 17, p. 787.

ANIMAL PRODUCTION.

Cattle feeding experiments, H. R. SMITH (*Nebraska Sta. Bul. 93, pp. 23, fig. 1*).—Continuing earlier work (E. S. R., 17, p. 688) the relative merits of different sorts of coarse fodder for supplementing corn and the value of different concentrated feeds as compared with alfalfa were studied with 6 lots of 10 steers each.

In the first test the rations consisted of snapped corn with prairie hay and with corn stover, each alone and with equal parts of alfalfa hay, snapped corn, and alfalfa hay, and with corn fodder (entire plant and ears) and alfalfa hay. In the 12 weeks covered by the period the average daily gain per steer ranged from 1.02 lbs. on snapped corn and corn stover to 2.06 lbs. on snapped corn and alfalfa hay. The greatest range in grain consumed per pound of gain was also noticed with these lots, being 4.6 lbs. on the alfalfa hay ration and 9.25 lbs. on the corn stover ration. The greatest amount of coarse fodder per pound of gain, 22.44 lbs., was also noticed with the last-mentioned lot, and the smallest amount, 10.47 lbs., with the lot fed prairie hay and alfalfa hay with snapped corn. Gain was most cheaply made on snapped corn with corn stover and alfalfa hay, costing 5.01 cts., and was dearest on snapped corn and prairie hay, costing 8.76 cts. per pound.

The steers were followed by pigs, and the value of the pork produced, as a by-product for each pound of gain made by the steers ranged from 0.7 cts. with the snapped corn, prairie hay, and alfalfa hay to 1.18 cts. on the snapped corn and prairie hay ration.

As pointed out by the author, in each of the 4 lots where alfalfa, a coarse fodder rich in protein, was used, the gains were larger than in the other cases and were made on less feed and at a lower cost. Feeding alfalfa with prairie hay 1:1 as compared with prairie hay effected a saving of 40 per cent of the corn required per pound of gain and 47 per cent when fed with corn stover as compared with stover without alfalfa. "The larger saving of corn in the case of stover was no doubt due in part to the fact that stover is more deficient in protein than is prairie hay." The amount of feed wasted "was very slight in case of alfalfa and very considerable with the corn stover. From one-third to one-half of the lower part of the cornstalk was thrown out because of its being refused by the cattle."

"Alfalfa hay is pronouncedly superior to prairie hay for beef production, and the more rapid the extension of the area of land devoted to the production of alfalfa, supplanting the less valuable and lower yielding native hay, the more rapid will be the production of wealth from our soil.

"Native prairie hay, if for any reason it is most available for feeding purposes, should not be fed with corn alone, but rather with corn supplemented

with a small quantity of some protein food, such as oil meal, to give more nearly a balance of nutrients in keeping with animal requirements.

"Cornstalks cut and put in the stock immediately after the ears ripen possess a food value which can not consistently be ignored by the farmer, and existing land values warrant the larger utilization of this roughness by the adoption of methods of harvesting that will make such material more valuable for feeding purposes."

After an interval of 3 weeks the cattle used in the preceding test were again subdivided into 6 lots of 10 steers each. Corn alone, corn and bran 3:1, and corn with oil meal and with cotton-seed meal 9:1, with prairie grass hay in every case, were compared, as well as corn and corn-and-cob meal each with alfalfa hay and prairie hay 1:1. The feeding period covered 8 weeks. The average daily gain ranged from 1.27 lbs. per head on corn and prairie hay to 2.52 lbs. on corn and oil meal. The grain eaten per pound of gain ranged from 9.77 lbs. on both the corn and oil meal and the corn-and-cob meal and alfalfa hay rations to 15.10 lbs. on corn, and the hay eaten from 2.7 lbs. on corn and oil meal to 3.94 lbs. on corn. The cost of a pound of gain was largest with the last-mentioned lot, being 10.74 cts., and lowest, 7.4 cts., with the lot fed corn and alfalfa hay.

Pigs followed the steers, and the value of the pork produced as a by-product to each pound of gain made by the steers ranged from 0.68 ct. in the case of the corn and cotton-seed meal ration to 2.05 cts. in the case of the corn ration.

"Conclusions can not be drawn from the results of a single experiment, but the records of this test indicate that oil meal is superior to cotton-seed meal. The greater profits, however, from oil meal were due in part to the fact that the hogs behind the cattle fed cotton-seed meal made much smaller gains.

"The records in this experiment also indicate that oil meal has a value nearly three times as great as bran. . . .

"None of the protein concentrates proved as cheap as alfalfa hay."

Our available stock foods, W. H. DALRYMPLE (*Louisiana Stas. Bul.* 86, pp. 74, figs. 11).—Available data regarding the composition and nutritive value of a number of feeding stuffs, especially those of local origin, are spoken of, and sample rations for different farm animals are suggested in which such feeding stuffs are used.

Requests for information regarding the feeding of low-grade sugar cane molasses or blackstrap were sent to a number of planters. Opinions regarding its use were not entirely uniform, but in general they showed that this material was extensively used and very favorably regarded. The consumption of molasses per head per day on 47 sugar estates averaged about 10 lbs., the range being from 2 or 3 lbs. to a little over 21 lbs. The majority of those supplying information conceded that molasses effected a saving of 10 to 50 per cent in feed bills. The opinion was generally advanced that feeding molasses diminished the number of cases of dietetic ailments, such as colic, etc., and improved the health and therefore the capacity of the animals for work.

"Some feed molasses as an ingredient of a mixed ration; others, by itself, ad libitum, in an open receptacle; while still others adopt both methods. . . . The fewer number of planters feed their animals 3 times per day, the majority twice."

In a number of cases the replies received stated that molasses was fed to all classes of farm animals except poultry as well as to horses and mules.

Value of ground maize cobs, R. H. GENNYS (*Agr. Gaz. N. S. Wales*, 17 (1906), No. 5, pp. 475, 476, fig. 1).—Data are summarized regarding the composition and feeding value of corn-and-cob meal, and a test briefly noted in which

somewhat shriveled and immature corn ears, having no market value, were coarsely ground and the corn-and-cob meal fed to 11 pigs for 21 weeks. The ration consisted entirely of the corn-and-cob meal mixed with water. The calculated profit was about \$56. Farm horses were also fed on corn-and-cob meal with chaff. "They were at work fairly hard during the period and held their own well."

Utilization of fresh pea pods and asparagus waste, A. MÜLLER (*Konserv. Ztg.*, 1906, p. 40; *abs. in Chem. Ztg.*, 30 (1906), No. 72, *Repert. No. 30*, p. 295).—With a view to determining their feeding value the author made analyses of the asparagus waste and the fresh pea pods which accumulate at canneries.

The asparagus waste contained, on a dry matter basis, 5.99 per cent water, 20.97 per cent protein, 2.00 per cent fat, 37.13 per cent nitrogen-free extract, 25.84 per cent crude fiber, and 7.99 per cent ash, and the pea pods 7.88 per cent water, 16.00 per cent protein, 1.25 per cent fat, 50.69 per cent nitrogen-free extract, 18.85 per cent crude fiber, and 5.33 per cent ash.

Potato drying in Germany, PAROW (*Mitt. Deut. Landw. Gesell.*, 21 (1906), No. 25, pp. 264-266).—When potatoes can not be otherwise utilized it is stated that they may be dried and used as a feeding stuff. Information is given regarding the method and cost of drying and the value of the dried product.

Concerning the poisonous properties of peanut cake, F. SCHMIDT (*Chem. Ztg.*, 30 (1906), No. 73, p. 882).—The author attributes the harmful effects sometimes noted after feeding peanut cake principally to the presence of sand. Fermentation, bacterial growth, and adulteration with castor beans are also regarded as causes.

A native plant recommended as a fodder for the dry country, J. H. MAIDEN (*Agr. Gaz. N. S. Wales*, 17 (1906), No. 7, p. 719).—A brief note to the effect that the Noogoora bur (*Sida corrugata*, var. *trichopoda*) is valuable as a fodder plant. It is said that sheep fatten quickly on it and that cattle relish it, but that horses do not care much for it.

Concerning the nutritive value of amid substances, B. VON STRUSIEWICZ (*Inaug. Diss. Univ. Göttingen* [1906]; *abs. in Jour. Landw.*, 54 (1906), No. 1, p. 81).—Feeding experiments with sheep to study the nutritive value of the amid substances in beets and beet molasses led to the conclusions that such material is fully equal to digestible protein, and that in estimates of the nutritive value of feeding stuffs the amid nitrogen should not be subtracted from the digestible protein and reckoned with the nitrogen-free extract.

Sheep and saltbushes, Coolabah farm, R. W. PEACOCK (*Agr. Gaz. N. S. Wales*, 17 (1906), No. 7, pp. 701-707, *figs. 3*).—On saltbush alone, 5 sheep fed in a pen lost 3.2 lbs. per head in a year's feeding period, but were apparently healthy, while sheep fed on saltbush supplemented with hay, grass, green feed, etc., gained 12.5 lbs. each during the same time. Six sheep running in a saltbush paddock for a year gained on an average 11.17 lbs. each. Feeding saltbush diminished the yield of wool somewhat, but the fleece was of good quality. The saltbush mutton was dry and tough, resembling mutton produced during time of drought, but the flavor was sweet. "Very little fat was on inside—the kidneys were just covered with a thin film; also paunch." The value of the different varieties of saltbushes may perhaps be gauged by the partiality of the sheep for them. The following varieties were fed: *Atriplex nummularia*, *A. vesicaria*, *A. angulata*, *A. semibaccata*, and *A. leptocarpa*, the first mentioned being the chief feed throughout the test. "They relished a change from one variety to another at all times, but were more partial to *A. angulata* than the other varieties."

The cross breeding of sheep, J. S. LOOSLEY (*Rhodesian Agr. Jour.*, 3 (1906),

No. 6, pp. 619-624, pls. 3).—A summary of data on the success which has attended the crossing of native Kafir and Africander ewes with imported well-bred rams. Under present conditions, in the author's opinion, farmers can not do better than to breed such crosses.

The swine industry in Ontario (*Ontario Dept. Agr. Bul. 149, pp. 36*).—On the basis of answers received to a circular list of questions, data are summarized regarding the condition of the swine industry in the various counties of the Province of Ontario.

The majority of the counties gave preference to the Yorkshire breeds. Pure-bred sires are used almost entirely. The general tendency throughout the province is slightly to increase the production of pork. The average cost of summer feeding is estimated to be \$4.51 per hundredweight and winter feeding \$5.38. "A number of correspondents, especially in western Ontario, state that with comfortable quarters and roots the cost of feeding is no greater in winter than in summer."

The bulletin also contains a summary of data on the poultry industry by G. E. Day.

Inheritance of color coat in swine, W. J. SPILLMAN (*Science, n. ser., 24 (1906), No. 614, pp. 441-443*).—A brief statement regarding breeding experiments with Tamworth, Yorkshire, Poland China, and Duroc Jersey pigs and the wild boar of Europe, conducted by Q. I. Simpson.

The results are not regarded as conclusive, "but they do render it highly probable that there are good Mendelian characters in this class of animals."

Origin and history of the horse, H. F. OSBORN (*Proc. N. Y. Farmers, 1905-6, pp. 5-20, pls. 19*).—The origin of the horse, distribution and migration of horses, and related questions are discussed very largely on the basis of the author's recent studies and discoveries of fossil remains.

Poultry (*[Quart.] Rpt. W. Va. Bd. Agr., 1906, No. 2, pp. 159, figs. 38*).—Articles by a number of writers on various topics connected with poultry raising are included in this report, as well as a summary of experiment station work on the subject, one of the articles being by K. C. Atkeson on white guinea fowls (pp. 40, 41). It is stated on the basis of personal experience that this variety is more satisfactory than other varieties, since they are tamer and lay in the chicken house instead of seeking out-of-the-way nests, while they are particularly satisfactory for table fowls.

"The young guinea does not require as much care as the turkey, but if hatched early will require more care than chickens. June [in West Virginia] is about the best month to have them hatch, and if they are kept confined for the first few days so that they will not exercise too much, they will get along all right as they are exceptionally free from disease."

Poultry, A. G. GILBERT and V. FORTIER (*Canada Cent. Expt. Farm Bul. 54, pp. 75, pls. 5, figs. 55*).—In this bulletin, which summarizes data on the rearing, feeding, and management of poultry, experience gained at the experimental farms has been summarized, as well as general information.

The breeding, feeding, and general management of poultry, A. G. Gilbert (pp. 5-28).—The author calls attention to the principles which underlie profitable poultry raising, describes breeds, and discusses rations and manner of feeding them, the molting of fowls and methods of shortening this period of nonproduction, and related topics. There are also short chapters on turkeys, ducks, and geese.

On incubation, the rearing and fattening of chickens and fowls, poultry buildings, etc., V. Fortier (pp. 29-75).—The author treats of incubation, natural and artificial poultry raising, the growth of chickens and the fattening of

hens, poultry buildings and runs, and the treatment of poultry diseases, injuries, etc.

Poultry for export. G. BRADSHAW (*Agr. Gaz. N. S. Wales, 17 (1906), No. 8, pp. 826-858, figs. 11*).—A competition in raising poultry for market showed that under local conditions chickens can be raised to three and a half or four months at a cost of twenty-five cents each. Detailed statements are made regarding the quality of the poultry shipped to the London market and the condition of the poultry industry as a whole. The author believes that the local demand for poultry of good quality can be greatly increased.

Meat powders, etc., for poultry food (*Agr. Gaz. N. S. Wales, 17 (1906), No. 8, p. 859*).—An analysis is reported of a poultry food of animal origin.

Color in birds and color feeding, L. DECHMANN (*Rel. Poultry Jour., 13 (1906), Nos. 6, pp. 618, 619, 628; 7, pp. 683, 684, 702, 703, figs. 3; 8, pp. 755-757, 800, 801, figs. 4*).—The general question of color of poultry feathers and factors which affect it are considered and data summarized on the possibility of influencing the color of feathers and shanks by colored light and by feeding pigment.

The castration of ostriches, ELLEY (*Agr. Jour. Cape Good Hope, 29 (1906), No. 3, pp. 349-354, fig. 1*).—The operation of castrating ostriches is described. It is claimed that castrating induces increased weight of feathers, better physical condition of the birds in times of drought or scarcity, and a probable improvement of the flesh, provided the birds should be used as food, while it lessens the dangers from fighting.

DAIRY FARMING—DAIRYING—AGROTECHNY.

On the influence of asparagin on the production of milk and its constituents, T. PFEIFFER, W. SCHNEIDER, and A. HEPNER (*Mitt. Landw. Inst. Breslau, 3 (1906), No. 5, pp. 747-770*).—In experiments with 3 goats in continuation of earlier work (*E. S. R., 17, p. 396*), the addition of 45 gm. of asparagin daily to a basal ration was compared with the addition of 58 gm. of aleurone to the same ration. The results as judged by the increase in the yield of milk, total solids, and fat were almost as favorable for the asparagin as for the aleurone. When the asparagin was fed, however, the live weight of the animals decreased, while a slight increase was observed when the aleurone was fed. It is therefore concluded that the asparagin increased the milk production at the expense of body weight, and that this amid in contrast to aleurone and other proteids is not to be classed as a true nutrient, but as a condimental or stimulating substance.

Report of the Spotted Swiss Cattle Breeders' Association, 1905 (*Ann. Agr. Suisse, 7 (1906), No. 5, pp. 285-324, pl. 1*).—The average annual yield of 88 cows of this breed was 3,608 kg. of milk, showing an average fat content of 3.93 per cent and total solids of 13.04 per cent.

Examination of colostrum of goats, M. SIEGFELD (*Milchw. Zentbl., 2 (1906), No. 8, pp. 360-363*).—The analysis of a sample of colostrum obtained during the first day of lactation showed the following composition: Total solids, 28.16; total proteids, 8.40; casin, 3.68; fat, 14.70; sugar, 2.94; and ash, 0.99 per cent. On the second and third days the total proteids decreased to 4.14 and 4.46 per cent, respectively, and the fat to 5.10 and 5.50 per cent. The fat obtained during the second and third days showed a Reichert-Meissl number of 28.7, a Polenske number of 5.15, a saponification number of 227.2, and an average molecular weight of the nonvolatile fatty acids of 259.7. The percentages of cholesterolin and lecithin were respectively 0.042 and 0.091.

Market milk investigations. II, The milk and cream exhibit at the National Dairy Show, 1906, C. B. LANE (U. S. Dept. Agr., Bur. Anim. Indus. Bul. 87, pp. 21, pls. 4).—This bulletin gives the results of an experiment in judging or scoring milk and cream in a contest conducted at the National Dairy Show held in Chicago February 15–24, 1906. The work was designed to be educational in character by showing some of the possibilities in the handling and keeping of milk and cream.

The exhibits were divided into 3 classes—certified milk, market milk, and cream. The conditions of entry required that the milk or cream be a fair sample of the product as sold by the exhibitor and that it be free from preservatives and not pasteurized or sterilized. All the milk and cream entered in the contest was produced on February 12, packed in ice, shipped to Chicago, and scored on February 15. The number of exhibitors in the 3 classes mentioned were, respectively, 8, 23, and 17.

For certified milk the numerical scores allowed for perfect were as follows: Flavor, 40; chemical qualities, 20; keeping qualities, 30; and general condition and appearance of package and contents, 10. For market milk the corresponding points allowed were 40, 25, 25, and 10; and for cream 40, 20, 25, and 15. The tests used in judging flavor, chemical qualities, and keeping qualities are mentioned, and the appearance of the packages and contents in the different exhibits is described and illustrated.

The certified milk showed a great difference in flavor, but in no instance was this pronounced disagreeable. The fat content of the samples ranged from 3.8 to 5.3, averaging 4.5 per cent. The percentage of total solids ranged from 12.40 to 13.94 and averaged 13.33. The number of bacteria ranged from 0 to 51,000. The percentage of acidity varied from 0.171 to 0.198 and averaged 0.186. The numerical scores varied from 87 to 98 and averaged 94.8. The highest score was obtained by a Maryland exhibitor, whose dairy is briefly described.

The market milk, in some instances, had an undesirable flavor. The fat content ranged from 2.6 to 7.1 and averaged 4.5. The total solids ranged from 11.42 to 16.38 and averaged 13.49. The acidity ranged from 0.171 to 0.258 and averaged 0.200 per cent. The number of bacteria ranged from 400 to 21,000,000 per cubic centimeter. The total score ranged from 71 to 96 and averaged 89.7. The market milk receiving the gold medal was exhibited by a Wisconsin dairyman under conditions which are briefly described.

The fat content of the cream samples ranged from 17 to 44 per cent, the acidity from 0.171 to 0.270 per cent, the number of bacteria per cubic centimeter from 0 to 2,810,000, and the total scores from 86 to 98. Brief mention is made of the conditions under which the cream receiving the highest reward was produced.

The results are considered most gratifying in showing that milk and cream produced under sanitary conditions can be shipped long distances and be held several weeks without other means of preservation than cleanliness and cold. Some of the certified milk samples were found sweet after 5 weeks. Some of the cream was sweet and palatable after a period of 7 weeks. The certified milk was found quite superior to the market milk. As a large percentage of the samples of market milk remained sweet for 1 week in the exhibit case at a temperature of about 50° F., it is considered as demonstrated that market milk will keep for several days if handled with reasonable care and kept at a temperature below 50°. The medals were won by herds largely of mixed breeding, indicating that the sanitary conditions and methods of handling milk are of more importance than the breed of cows.

A discussion on milk supply (Brit. Med. Jour., 1906, No. 2386, pp. 669–

674).—This discussion before the Toronto meeting of the British Medical Association was opened by papers on The Protection and Control of the Milk Supply, by R. Harcourt; The Sanitary Control of the Milk Supply, by J. Glaister; and The Protection and Control of Milk Supplies, by H. C. Pattin.

In these papers and the general discussion which followed various phases of the milk-supply problem were considered and the conditions required of milk in the light of modern research set forth. A resolution was adopted urging the better enforcement of British laws concerning the housing of dairy cattle and the inspection of animals and dairies.

On the sugar in milk, J. SEBELIEN (*Upsala Läkareförs. Förhandl., n. ser., 11 (1906), Sup., pp. 10*).—A considerable difference was observed between the amount of sugar in milk as determined by polarimetric and gravimetric methods. This difference is attributed to the presence of a pentose corresponding in amount to 0.07 per cent of arabinose.

On the composition of tuberculous milk, A. MONVOISIN (*Rev. Gén. Lait., 5 (1906), Nos. 20, pp. 457-463; 21, pp. 492-498*).—Nine examinations during 1 month were made of the milk of a cow affected with mammary tuberculosis. The results showed a diminution in acidity, an increase in total nitrogen, a decided and progressive decrease in the amounts of fat and lactose, a marked increase in sodium chlorid, and a lowering of the index of refraction. Contrary to results reported by other observers, the freezing point was found to remain very constant.

On the so-called reductase in milk, H. SMIDT (*Arch. Hyg., 58 (1906), No. 4, pp. 313-326*).—The author discusses the reduction of methylene blue by milk as affected by the growth of bacteria. He concludes that the reduction of a solution of methylene blue and formaldehyde by fresh milk is not due to bacteria, but to an enzym secreted with the milk which decomposes the aldehyde, and which he, therefore, designates aldehyde catalase. This ferment is not considered a reductase, as the reducing action on methylene blue is due to the formaldehyde. The presence of a true reductase in milk, according to the author, has not yet been proved. A distinction is made between aldehyde catalase and superoxydase, both of which are present in milk.

The author finds that the reducing power of milk runs parallel with the development of bacteria, and, as suggested by Neisser and Wechsberg, believes that this fact may be utilized in milk hygiene. In raw milk methylene blue in the absence of an aldehyde is reduced, according to the author, only by the action of bacteria. Without working out a practical method he concludes as the result of his own experiments that milk of which 0.1 cc. is reduced by 4 cc. of a 0.003 per cent solution of methylene blue at 37° C. within 2 hours is objectionable on the ground of an excessive bacterial content.

A method of obtaining milk free from living tubercle bacilli and other organisms and not materially changed in its properties, H. MUCH and P. H. RÖMER (*Beitr. Klinik Tuberkulose, 5 (1906), No. 3, pp. 349-364*).—The milk is drawn with great care into a pail containing 3.3 cc. of a 30 per cent solution of hydrogen peroxid, or 33 cc. of a 3 per cent solution for each liter of milk to be obtained. The milk is allowed to stand for 12 to 14 hours, when it is heated to 52° C. for 1 hour. Five to 8 hours later a preparation, designated normal catalase, is added to the milk in the proportion of 4 drops per liter, which decomposes all the hydrogen peroxid and completes the process. The authors designate the product perhydrase milk. The method is said to produce no modification in the color, taste, or other properties of the milk, and to render it sterile.

Influence of light on perhydrase milk, H. MUCH and P. H. RÖMER (*Berlin*,

Klin. Wchenschr., 43 (1906), Nos. 30, pp. 1004-1007; 31, pp. 1041-1046).—The authors observed changes in the color, odor, and taste of milk previously sterilized with hydrogen peroxid and exposed to the light. Similar changes were observed in milk powder. The investigations indicated that these changes were produced by the combined action of oxygen and light and that they affected mainly the fat.

Different colored bottles were filled with the milk and exposed to the sunlight. The results showed that the red and green rays were without influence, while the ultra-violet, blue, and yellow rays produced marked changes. The same differences were observed when uncolored bottles filled with milk were wrapped with different colored silk paper. In order to prevent changes in the milk it is therefore necessary to exclude the light or wrap the bottles in red or green paper.

Experiments were made with mice to determine if the modified milk has injurious properties. While the results did not warrant positive conclusions, the authors believe that the use of such milk may not be without bad effects on infants.

The use of sodium citrate as a modifier of cows' milk, J. W. ENGLAND (*Jour. Amer. Med. Assoc.*, 47 (1906), No. 16, pp. 1241-1243, figs. 16).—The author concludes from the experimental data reported in this article that when citrated milk is brought into contact with the gastric juice, the sodium citrate is decomposed by the hydrochloric acid into sodium chlorid and citric acid and that the resulting sodium chlorid exerts important physical, chemical, and physiological influences in the digestion of the milk proteids. The citric acid liberated is not believed to have any greater therapeutic value than the hydrochloric acid. In the cold, sodium citrate has no decomposing action on calcium casein.

Condensed milk, P. DIFFLOTII (*Indus. Lait [Paris]*, 31 (1906), No. 32, pp. 523-525).—Notes are given on the manufacture of condensed milk without the addition of cane sugar. Samples so prepared contained a much higher percentage of water than usual. The composition of condensed milk made from whole milk without the addition of cane sugar was as follows: Water 61.46, proteids 11.17, fat 11.42, lactose 13.96, and ash 1.99 per cent; and that from skim milk as follows: Water 68.62, proteids 12.34, fat 0.26, lactose 15.73, and ash 2.96 per cent.

Variations in the test of separator cream (*Kansas Sta. Bul.* 137, pp. 203-211).—The experiments reported in this bulletin show the extent of variations in the fat content of cream due to several causes. The principal results are stated as follows:

"1. The temperature of milk makes a difference of from one to five per cent in the test of cream at average skimming temperature, greater variation being caused in extreme cases.

"2. The amount of flush water used with average skimming temperatures makes a difference of from one to three per cent, in extreme cases making a difference as great as ten per cent.

"3. The variation in steadiness of the bowl makes a difference of from two to sixteen per cent, depending on the amount of vibration.

"4. The variation of the speed of the bowl causes a difference of from one to thirteen per cent in the test of cream, depending on the variation in speed.

"5. The amount of milk allowed to flow through the separator bowl from one-half to full capacity makes a difference of from one to six per cent, depending upon the divergence from full capacity of the machine.

"6. The amount of acid in the milk causes an irregular variation in the test of cream, depending upon the amount of acid it contains. Where the acid

reaches a high point, 0.3 to 0.4 per cent for instance, and the separator is used continuously for an hour or more, it will eventually clog the same as in the case of cold milk. The cream will then become thicker until the separator is entirely clogged. The extent of the clogging will depend on the amount of acid in the milk and the size of the machine. The higher the acidity and the smaller the machine the sooner the separator will clog."

Improving the quality of cream from inferior milk, W. D. SAUNDERS (*Virginia Sta. Bul.* 162, pp. 145-156, figs. 2).—In the method described in this bulletin sour or bad-flavored milk is closely skimmed and the cream so obtained is diluted to any desired extent with fresh skim milk.

In one of the experiments reported a composite sample taken from 12 lots of milk and cream showed an acidity of 0.24 per cent. The cream, as taken from the separator, showed an acid content of 0.117 per cent. The skim milk used for diluting the cream contained 0.15 per cent acid. The acidity of the mixture before pasteurizing was 0.13 per cent and after pasteurizing 0.121 per cent. A can of this cream which contained 40 per cent of fat was cooled to a low temperature, covered with a felt jacket about 1 in. thick, and shipped to New Orleans, the time in transit being about 36 hours. So far as known this cream reached its destination in prime condition and gave good satisfaction.

Two other experiments of a like nature are reported.

Effect of bacteria in wash water of butter (*Kansas Sta. Bul.* 138, pp. 212-222, figs. 2).—Experiments were conducted at the station at three different times of the year to determine the amount of contamination in various kinds of water used for creamery purposes. Determinations of the number of bacteria in well water, pasteurized, sterilized, filtered, and treated in other ways and in melted ice are reported, and scores are given of the butter washed with the different kinds of water. The conclusions drawn from the work are as follows:

"1. It is both practical and economical to sterilize wash water for butter if it can be cooled and used immediately. Otherwise, the practice is a useless expense.

"2. A filter for creamery water is only a source of contamination and filth unless frequently cleaned and refilled with fresh filtering material.

"3. Water melted from ice, even though kept at 50° F., may become filled with bacterial growth if allowed to stand for a few hours in a wooden tank from day to day without thorough cleaning. Great care should therefore be taken in the utilization of such water for cooling purposes.

"4. There is a direct relation between the bacterial content of the wash water used and the keeping quality of the butter.

"5. Water kept at a low temperature from 40° to 50° F. for a few hours inhibits the development of bacteria, or destroys from one-half to four-fifths of those present."

Investigations in the manufacture and storage of butter. II, Preventing molds in butter tubs, L. A. ROGERS (*U. S. Dept. Agr., Bur. Anim. Indus. Bul.* 89, pp. 13, fig. 1).—Notes are given on molds and experiments on preventing their growth in butter tubs are reported.

In each of 6 trials, 1 tub was soaked in cold water over night in the usual way, 1 was boiled 5 minutes in a saturated brine and left in the brine all night, 1 was soaked over night in a brine containing 9 per cent of commercial formalin, 1 was coated on the inside with paraffin, and 1 was immersed for a few seconds in a bath of paraffin at 250° to 260° F. All the tubs in each lot were filled from the same churnin; and otherwise treated alike.

Of the untreated tubs all became moldy. Of those treated with hot brine, 1

was badly molded, 1 slightly molded, and 1 molded on the outside. Of those treated with formaldehyde, 1 was badly molded, and of those coated with paraffin none showed any mold whatever. The author considers that dipping the tubs has no particular advantage over coating the inside. Directions are given for applying the paraffin and notes are given on the cost. The advantages of paraffining are summarized as follows: (1) Certain prevention of moldy tubs, (2) prevention of mold on butter and liner by avoiding air space, (3) neater appearance of tub, and (4) reduction of loss from shrinkage.

On butter powders, F. REISS (*Milch. Zentbl.*, 2 (1906), No. 8, pp. 368-370).—An unfavorable report is made upon the use of preparations designed to be added to cream for the purpose of increasing the yield or quality of butter. Tests were made of two such preparations.

Butter trade (London: [Bd. Agr. and Fisheries], 1906, pp. XL + 459).—This is a report of the committee of the Board of Agriculture and Fisheries of Great Britain appointed to consider the need of further legislation concerning the trade in butter and butter substitutes.

The report contains the evidence of 49 witnesses, legislation in other countries, and the conclusions of the committee which include among other recommendations that butter factories should be registered, that no substances be added to butter whereby the percentage of moisture is increased, that the addition to butter of any fat not derived from milk be expressly and directly prohibited, that neither butter nor margarin shall contain more than 16 per cent of water, that penalties for the importation of adulterated butter be proportional to the magnitude of the consignment, and that substances other than butter and margarin containing butter fat be sold with a limit of 24 per cent of moisture under a name approved by the Board of Agriculture and Fisheries.

On the influence of salting on the formation of holes in Emmenthal cheese, O. JENSEN (*Landw. Jahrb. Schweiz.*, 20 (1906), No. 8, pp. 437, 438).—Different quantities of sodium chlorid ranging from 0.5 to 10 per cent were added to a peptone bouillon containing calcium lactate and the medium inoculated with propionic-acid organisms. It was found that the presence even of 0.5 per cent of salt checked the development of the organisms and that 10 per cent prevented their growth entirely. This injurious influence upon the growth of bacteria is attributed to the formation of calcium chlorid which causes a precipitation of the proteids.

In earlier investigations the author found that the outer portions of Emmenthal cheese contained more salt than the interior of the cheese. This is therefore offered as an explanation why the outer layers of large Emmenthal cheeses and also small cheeses contain fewer holes than the central part of large cheeses.

On the lactic fermentation in Emmenthal cheese, O. JENSEN (*Ann. Agr. Suisse*, 7 (1906), No. 4, pp. 253-281; *Milch. Zentbl.*, 2 (1906), No. 9, pp. 393-414; *Rev. Gén. Lait.*, 5 (1906), Nos. 20, pp. 464-470; 21, pp. 481-492; 22, pp. 508-579).—Lactic ferments, according to the author, exercise an indirect influence in cheese ripening in restraining gassy fermentation and putrefaction, and a direct influence in the decalcification of the paracasein and the decomposition of the albuminoid substances.

In the investigations reported the author did not find as high a degree of acidity in Emmenthal cheese 4 hours old as was found by Peter (E. S. R., 16, p. 1019). The acidity of the whey in the interior of the cheese at this stage decreased from 28 to 11° (cubic centimeters of tenth normal sodium hydroxid solution required to neutralize 100 cc. of whey) as the temperature of cooking increased from 48 to 60° C. Lactic fermentation was apparently greatly reduced by heating the curd above 58°.

When the evening milk was kept cool over night the acidity of the whey in the cheese varied from 6 to 13°, and when the milk was kept warm from 16 to 26°. The highest degree of acidity found in cheese 4 hours old in these experiments was 29°. The ripening of the evening milk was, therefore, considered of great importance in the acidification of the whey in the cheese during the first 6 hours after manufacture.

The addition of 1 per cent of culture to the evening milk did not seem to increase the acidity. It is believed that acidification takes place mainly within the interior of the cheese, and in the early stages of this process the most important organism concerned is a hitherto unrecognized streptococcus, which is to be the subject of a special report. Later *Bacillus casci* ϵ predominates. This organism, considered the most important in the ripening of this cheese, reaches its maximum development soon after the cheese is made, which fact is believed to confirm the view previously put forth by the author that the ripening of hard cheese is due to the enzymes liberated by the disintegration of bacterial bodies which were formed in the cheese during the first few days.

In regard to the process of decalcification, the author concludes that in fresh Emmenthal curd inorganic calcium and inorganic phosphoric acid exist in the same proportions as in tricalcic phosphate, and that during the acidification of the cheese the greater part of the tricalcic phosphate is transformed into dicalcic phosphate, and hence does not pass into the whey.

In order to lessen the danger of gassy fermentation in Emmenthal cheese, it is recommended that the evening milk be held at a temperature of about 20°, or where much trouble of this kind is experienced that the evening milk be cooled and cultures of *Bacillus casci* ϵ and the streptococcus referred to be added to the milk before making into cheese.

Investigations of O. Johan-Olsen on the manufacture and ripening of cheese, *Iluss (Milchv. Zeitbl., 2 (1906), No. 8, pp. 363-368)*.—This is a review of the investigations of O. Johan-Olsen on the use of pure cultures of yeasts in the manufacture of various kinds of cheese.

A rennet-producing bacterium isolated from *Galium mollugo*, J. HOHL (*Landw. Jahrb. Schweiz, 20 (1906), No. 8, pp. 439-444*).—The organism isolated from this plant is described as a variety of *Bacterium synxanthum*. It was found to be capable of coagulating milk without the formation of acid. The author also notes the isolation from soil of a bacillus having the same properties as regards the coagulation of milk.

Review of the work of the season for 1905-6, J. A. KINSELLA (*New Zeal. Dept. Agr. Dairy. Div. Bul. 8, pp. 91, pls. 14*).—This report contains statistics on the exports of dairy products from New Zealand and discussions on a number of subjects of practical interest in dairying, such as salting butter, mottled butter, moisture in butter, paraffining butter boxes, use of preservatives, testing dairy herds, pasteurization, milking machines, etc. The exports during the year amounted to 314,165.5 cwt. of butter, valued at £1,696,493, and 121,322 cwt. of cheese, valued at £376,098. Some experiments in keeping butter at freezing temperatures from March 4 to May 8 are reported. None of the butter of first quality showed any appreciable deterioration during that time. The coating of butter boxes with paraffin is urged on the grounds of saving a considerable amount of shrinkage. Yearly records of 3 private dairy herds are included.

Nineteenth annual report of the Bern dairy school at Rütli-Zollikofen for the year 1905-6 (*Jahresber. Molk. Schule Rütli-Zollikofen, 19 (1905-6), pp. 56, pls. 2, figs. 2*).—In addition to an account of the educational work of this school, the report contains brief summaries of experimental work concerning the testing of milk, gassy fermentation in cheese, use of pure cultures

in the preparation of rennet, determination of the acidity in whey from cheese, and variations in the chemical composition of milk.

Report of the dairy institute at Proskau, 1905-6 (*Ber. Milchw. Inst. Proskau, 1905-6, pp. 29*).—A report of the work of this institute during the year, including analyses of a large number of samples of milk.

Officials, associations, and educational institutions connected with the dairy interests of the United States for the year 1906 (*U. S. Dept. Agr., Bur. Anim. Indus. Circ. 99, pp. 14*).

Production of lactic and acetic acids from milk sugar, KAYSER (*Indus. Lait. [Paris], 31 (1906), No. 36, pp. 586-589*).—The principles involved in the manufacture of lactic acid and acetic acid from milk sugar are briefly stated and figures given to show the profits in this industry.

Hawaiian waste molasses, S. S. PECK (*Hawaiian Sugar Planters' Sta., Div. Agr. and Chem. Bul. 18, pp. 28*).—It is stated that in the mills of Hawaii the waste molasses to each ton of sugar manufactured amounts to from 15 to 23 gal., averaging 55 per cent of sucrose. With a view to determining if the exhaustion of molasses depends upon the ratio existing between the invert sugar and inorganic salts as found by H. C. P. Geerligs in factories in Java, analyses were made of the products of a number of factories during 2 seasons. The methods of analysis employed and the results obtained are given in full. The author's summary is as follows:

"(1) The ratio of glucose to ash does not serve as an indication of the exhaustion of the Hawaiian molasses.

"(2) The limit of the further recovery of sugar is established principally by the viscosity of the molasses.

"(3) The viscosity of the molasses originates with the gums, and any method reducing the quantity of gums or their stickiness, makes for the possibility of further recovery of sugar.

"(4) The ashes of molasses and the composition of the ashes vary with the conditions of growth of the cane and the amounts of lime used in the clarification of the juices.

"(5) A high salt content in the irrigation water increases the potash and chlorin in the ash, but not to an appreciable extent the soda with which chlorin was originally combined."

The influence of selected yeasts upon fermentation, W. A. P. MONCURE, R. J. DAVIDSON, and W. B. ELLETT (*Virginia Sta. Bul. 160, pp. 97-120, figs. 2, charts 4*).—Brief notes are given on the changes which take place during the transformation of the fruit juice into an alcoholic beverage, the sources of yeasts in nature, and on the natural control of fermentation, and experiments showing the individuality of yeasts are reported.

Tests were made to determine the effect upon unfermented cider of two yeasts designated No. 37 and No. 66. Under identical conditions the yeast No. 37 liberated 18.9 gm. of CO₂, and yeast No. 66, 19.68 gm. The cider fermented with yeast No. 37 contained 4.56 per cent of alcohol and 0.472 per cent of acid. The cider fermented with yeast No. 66 contained 4.84 per cent of alcohol and 0.514 per cent of acid. The aroma produced by yeast No. 37 was pronounced very rich, fruity, and extremely pleasant, while that produced by yeast No. 66 was rather sharp and of an acid and slightly disagreeable nature. These 2 yeasts were further compared in some 34 tests. The results with both yeasts were compared with natural fermentation as regards the amount of carbon dioxide liberated and the composition of the fermented ciders. The percentage of alcohol produced by natural fermentation was 4.44; by yeast No. 37, 4.70; and by yeast No. 66, 4.83. The amount of yeast found necessary to dominate fermentation was 1 to 400 parts of must.

The station has a collection of about 70 pure cultures of yeasts, the more promising of which are briefly noted.

The influence of sulphurous acid on fruit wines, II. MÜLLER-THURGAU (*Centbl. Bakt. [etc.]*, 2. Abt., 17 (1906), No. 1-2, pp. 11-19).—In laboratory experiments during several years fresh pear juice was treated with sulphur dioxide in different amounts. In this way the development of injurious organisms such as lactic-acid bacteria was checked or prevented. The favorable influence of this treatment was the more marked the sooner it was applied after pressing. As compared with samples not treated with sulphur this method increased in general the alcoholic content of the fermented product and also the nonvolatile acids, but decreased the amount of volatile acids. The lactic acid in treated samples was only one-third that in untreated samples. The free sulphur dioxide disappeared rapidly so that only small quantities were present in the perry. The total amount of sulphur dioxide, however, showed no decrease. It is suggested that potassium metasulphid may be used instead of the sulphur dioxide.

The method was applied to perry making under practical conditions with equally satisfactory results. The use of 84 mg. of sulphur dioxide per liter was as favorable as a larger amount. The perry contained a total of 83 mg. of sulphur dioxide per liter with 4 mg. in a free form. The combined form is believed to be free from objections from the standpoint of health.

Filtration of wine, L. MOREAU (*Rev. Vit.*, 26 (1906), No. 663, pp. 229-234).—Analyses are reported of a number of samples of wine before and after filtration. The results showed a considerable modification in the composition of the wine. The method nevertheless is considered at times indispensable in clarification.

The manufacture of Jamaica rum, C. ALLAN (*West Indian Bul.*, 7 (1906), No. 2, pp. 141-152).—This report contains a description of the process of manufacturing rum in Jamaica, with analyses of a large number of samples of rum and of fermentation products of distilleries.

A complete course in canning (*Baltimore: The Trade*, 1906, pp. 176, fig. 1, map 1).—This book gives directions for the building of canning factories, discusses the economics of the business, and gives detailed formulas for the canning and preserving of all the vegetables, fruits, fish, meats, and soups commonly canned. Data for making jams, jellies, mince-meats, pie filler, spice mixtures, etc., are also given.

Flax spinning in France, C. J. KING (*Daily Consular and Trade Rpts.* [U. S.], 1906, No. 2663, pp. 4, 5).—This report on the spinning of flax and flax waste contains a description of a new method for the spinning of these articles which it is believed should be of considerable value in developing the linen industry in the United States. The new process, which is invented by A. Guillemand and protected by patent, consists in an adaptation to flax of the system now employed in spinning cotton.

Industrial by-products utilized in agriculture as foods and as fertilizers, E. COLLIN and É. PÉROT (*Les résidus industriels utilisés par l'agriculture comme aliments et comme engrais*. Paris: J. B. Baillièrè & Son, pp. XI + 299, figs. 93; *rev. in Mois Sci.*, 8 (1906), No. 3, p. 15).—The work deals with the by-products of the manufacture of oils, perfumes, extracts, etc., used in agriculture as foods or fertilizers. The first part gives general information regarding the source, composition, and use of oil cake and like products, but the second consists of original monographs on the morphology of oily seeds and fruits, and on the external appearance, microscopic character, chemical composition, sophistication and adulteration, uses, therapeutic value, poisonous

properties, and advantages and disadvantages of cakes used as foods and as fertilizers.

VETERINARY MEDICINE.

The veterinary service of the United States, R. OSTERTAG (*Das Veterinärwesen der Vereinigten Staaten von Nord-Amerika. Berlin: Richard Schoetz, 1906, pp. VIII + 151, figs. 17*).—The author spent 2 months in the United States for the purpose of studying our institutions designed for instruction in animal industry and veterinary science, the stock yards, abattoirs, cold storage plants, meat inspection, dairy farms, milk inspection, city milk supply, methods of combating various animal diseases, and other veterinary matters. The opinion of the author regarding the status of animal industry and veterinary science in this country is of considerable interest on account of his standing in Germany and his wide experience with these matters.

With regard to veterinary schools, the author speaks in high praise of 2 or 3 of them, but criticises the standard of instruction in some of the private schools without endowment in which the only source of income is from student fees. The systems of instruction in animal industry and dairying are considered as being of a very practical and efficient nature. Special mention is made of the Iowa Agricultural College in the line of animal industry and of the Wisconsin Agricultural College in dairying.

In summarizing his impressions of animal industry and veterinary science in the United States, the author states that veterinary education with us is still in its infancy, but shows many strong features, particularly the practical instruction in animal breeding and stock judging offered to students in veterinary science. The work of the Bureau of Animal Industry is praised for its efficiency, particular mention being made of the control work on Texas fever, sheep scab, tuberculosis, and hog diseases. The conditions which prevail on the better class of dairy farms and the regulations already in force in many cities for the inspection of milk conspire, in the author's opinion, toward furnishing an excellent city milk supply at a reasonable price.

The veterinary section, A. THEILER ET AL. (*Transvaal Agr. Jour., 4 (1906), No. 16, pp. 777-804*).—Although foot-and-mouth disease prevailed greatly in South Africa in 1893 no outbreak has occurred since 1903. The colonial laws regarding this disease are apparently satisfactory. Notes are given on the present status of Texas fever, African coast fever, anthrax, and glanders.

In the case of glanders, attention is called to the danger from horses affected with a mild form of the disease. It is believed that if an indemnity were paid for such cases by the government the owner's consent to the destruction of the animal could readily be obtained, and the spread of the disease would thereby be checked. Notes are also given on sheep scab and horse sickness.

Results of investigations in the field of general pathology and pathological anatomy, O. LUBARSCH and R. OSTERTAG (*Ergeb. Allg. Path. Mensch. u. Tiere, 10 (1904-5), pp. XI+989, pl. 1*).—As usual in this series of reports, a detailed review is given of literature bearing on the pathology of man and animals, together with classified bibliographical references. A review of Russian literature on general pathology for the years 1904-5 is presented by R. Weinberg. Particular attention was given to trypanosomiasis, tuberculosis, and tumors. The review of literature on tuberculosis was prepared by A. Eber.

The army horse in accident and disease, A. PLUMMER ([*U. S. War Dept.*], 1906 [rev. ed.], pp. 116, pls. 22).—The school of application for cavalry and field artillery at Fort Riley, Kansas, offers opportunity for the practical training of students in the management of the common diseases of horses and mules and

in the care of horses in health. The present volume is prepared as a manual for the use of students in the training school for farriers and horseshoers. It contains a brief account of the symptoms and treatment of the common diseases of horses arranged according to the part of the body affected or the nature of the disease. The conformation and points of the horse are also described and notes are given on stable management, anatomy, and the use of medicines.

Modern phthisiogenetic and phthisiotherapeutic problems from an historical standpoint, E. VON BEHRING (*Beitr. Expt. Ther.*, 1906, No. 11, pp. XXXVI+156).—Since 1901 the author and his disciples have issued numerous publications dealing with the progress of their work on various problems of tuberculosis. The present account is in the nature of an historical summary of this work with explanations of its bearing upon the practical control of tuberculosis and with the consideration of certain points of priority which have arisen. The use of the author's bovovaccin has been tested on such a large scale that it is now believed to rest upon the firm basis of practical experience. Many of the controversial matters relating to phases of the tuberculosis problem are discussed, particularly the question regarding the chief source of contagion in tuberculosis. The author adheres to his position that tuberculosis in both man and animals is very largely transmitted through the alimentary tract rather than through the lungs. Infection, in the author's opinion, takes place chiefly during an early age.

In the near future it is stated that the author's new method for the control of tuberculosis by the use of tuberculase will be explained in greater detail and will be offered for experimental use. This material is obtained by first extracting from the tubercle bacilli those substances which are soluble in water, alcohol, and salt solution, after which the remainder of the bacterial bodies is thoroughly pulverized and prepared for use in a liquid form. At first the method appeared not to promise much from a practical standpoint for the reason that the elaborate method necessary for obtaining tuberculase made the material altogether too expensive. Much improvement has been made in cheapening the method of manufacture, and the author therefore hopes to be able to prepare the material at a reasonable cost. Tuberculase is not infectious and does not contain living tubercle bacilli. It is, therefore, recommended by the author in the treatment of human tuberculosis. The use of a vaccine such as is used in preventing bovine tuberculosis is not recommended in the case of man.

The intestinal origin of pulmonary tuberculosis, A. CALMETTE and C. GUÉRIN (*Ann. Inst. Pasteur*, 20 (1906), No. 5, pp. 353-363).—In a previous investigation by the authors it was found that, contrary to von Behring's contention, adult animals, at least in the case of goats, became infected with tuberculosis through the alimentary tract more readily than young animals. In the present article an account is given of further work along this line on cattle. In these experiments virulent bovine tubercle bacilli were used and were introduced into the second and third stomachs by means of a sound passed down the esophagus. The authors believe that the chief reason why experiments in the alimentary infection of cattle have so frequently failed is that tubercle bacilli given in the form of a drench reach the rumen and there become so greatly diluted in a large mass of material in this organ that infection rarely takes place.

In experiments reported by the authors, 4 cows previously determined to be free from tuberculosis were inoculated by the method just described. All of these animals became tuberculous, and the authors conclude that animals may readily contract tuberculosis through the alimentary tract both in young life and at an adult age and without the development of any lesions of the walls of the alimentary tract. According to the authors' observations, tubercle bacilli

are retained in the mesenteric ganglia in young animals and remain in these ganglia sometimes for years, the lesions ultimately healing. In adult animals, on the other hand, the defensive action of the ganglia is less active and the tubercle bacilli are carried more readily into the general circulation, thus reaching the lungs. So-called primary pulmonary tuberculosis of the adult is, therefore, most often of intestinal origin.

Intestinal origin of pulmonary tuberculosis, III. A. CALMETTE and C. GUÉRIN (*Ann. Inst. Pasteur*, 20 (1906), No. 8, pp. 609-624).—An elaborate review is presented of the literature relating to this subject, particular attention being given to an examination of the evidence presented in favor of assuming inhalation as one of the chief sources of tuberculosis. The authors believe, as a result of their studies and direct experiments, that in the immense majority of cases the pulmonary or pleural localization of tuberculous lesions is due to tubercle bacilli carried to the point in question in leucocytes and introduced primarily into the alimentary tract. It is believed, therefore, that animals and man could be practically protected against tuberculosis if the food and water in all instances could be so sterilized as not to contain any tubercle bacilli. In the authors' experience a single intestinal infection with tubercle bacilli produces a mild form of the disease, during which the animal reacts to tuberculin for a period of 1 to 2 months, but frequently recovers, to all appearances, after such a period. In these cases the authors have established beyond question that the animals had recovered and that the animals were insusceptible to the disease.

On the other hand, in all cases where a repeated intestinal infection took place, especially if the different infections followed one another at short intervals, the tuberculous lesions developed rapidly and never healed. In the authors' opinion these facts explained the frequently observed presence of healed tubercles in man and animals.

The experimental production of transmissible varieties of tubercle bacilli, S. ARLOING (*Compt. Rend. Acad. Sci. [Paris]*, 142 (1906), No. 25, pp. 1395-1397).—The possibility of modifying the virulence of the tubercle bacillus has long been known, but some difficulty has been experienced in securing a race of the bacilli which would show a low virulence and retain it when transferred from one culture to another. The author states that he has succeeded by means of the use of heat in obtaining a culture of tubercle bacilli of such low virulence that the bacilli produce no true infection, but are absorbed and exercise merely a vaccinating effect. The author has also succeeded in making frequent transfers of these bacilli from one culture to another without altering their virulence. The race of bacilli with which the author has experimented has, therefore, become for practical purposes a vaccine without the power of producing infection.

Fat-free tubercle bacilli, H. VALLÉE (*Compt. Rend. Soc. Biol. [Paris]*, 60 (1906), No. 22, pp. 1020-1022).—According to the author's experiments tubercle bacilli retained all of their toxic products after being deprived of their fat content. This point was tested by inoculation of calves, horses, and other animals.

Tuberculosis as a cause of condemnation of food animals, REUTER (*Vrtlschr. Bayer. Landw. Rath.*, 11 (1906), No 2, Sup., pp. 542-557).—Condemnation of food animals on account of tuberculosis, according to German law, requires the determination of the facts that the animal was intended for food and is affected with tuberculosis to such an extent that more than half of the animal is totally unfit for food or can only be used for food after being treated. The author discusses the legal and sanitary difficulties which have arisen in this connection and considers that a new definition is required of the stage of tuberculosis which necessitates condemnation of the animal.

Retrogressive infection in the development of tuberculosis, A. KREINBERG (*Ztschr. Fleisch u. Milchhyg.*, 16 (1906), No. 10, pp. 322, 323).—On account of the great importance of tuberculosis in meat inspection, the author made a study of the course which infection takes in different animals during the progress of the disease. It is found that in some cases infection spreads not altogether in the direction of the currents of blood and lymph. Occasionally the lymph stream appears to become checked and to be turned in a backward direction so that infection sometimes appears in parts of the body where it would not naturally be expected.

Immobility caused by cerebral tuberculosis in cattle, C. BESNOIT (*Rev. Vét. [Toulouse]*, 31 (1906), No. 9, pp. 577-585, fig. 1).—Brief mention is made of the peculiar symptoms, including inability to move, which appear in cases of cerebral tuberculosis in horses and cattle. In cattle this form of tuberculosis is considered by the author as being quite frequent and details are given concerning the post-mortem lesions found in one case.

Tuberculosis in the bee moth, S. METALNIKOFF (*Centbl. Bakt. [etc.]*, 1. *Abt., Orig.*, 41 (1906), Nos. 1, pp. 54-60; 2, pp. 188-195, pls. 2).—On account of the fact that the bee moth lives largely on wax in bee colonies, it is obvious that it possesses a ferment capable of dissolving or digesting this wax. The author was, therefore, led to study the action of this ferment upon the wax capsules of tubercle bacilli. It was found that the bee moth is quite immune to tubercle bacilli obtained from man, cattle, or birds. This immunity is due to the very rapid destruction of the tubercle bacilli by means of phagocytes and inside of special capsules formed in the blood or lymph. Even after injection with relatively enormous doses of tubercle bacilli the organism of the bee moth seems to suffer no harm and all of the bacilli are found inside of phagocytes or other cells within 1 hour. The bee moth, however, appears not to be able to destroy tubercle bacilli obtained from fish. After inoculation with these organisms a pronounced phagocytosis takes place, but the phagocytes do not overcome the bacilli and the moth finally dies.

Immunity toward tuberculosis, S. METALNIKOFF (*Centbl. Bakt. [etc.]*, 1. *Abt., Orig.*, 41 (1906), No. 3, pp. 391-396).—Blood and extracts of various kinds from bee moths were used in treating guinea pigs to determine the effect of such treatment upon the course of infection with tuberculosis. It was found that the blood and body extracts of bee moths were capable of greatly prolonging the life of guinea pigs infected with tubercle bacilli. It was also found that the blood of the bee moth had the power of destroying tubercle bacilli *in vitro*.

Combating tuberculosis by means of special offices of information, J. HÖGILD (*Maanedskr. Dyrtaeger*, 18 (1906), No. 2-3, pp. 114-128).—The mere use of tuberculin for determining the presence of tuberculosis in a herd of cattle is not a satisfactory means of controlling the disease unless further regulations are adopted in order to make the information gained by the use of tuberculin more immediately effective.

The author recommends that special offices be created for reporting cases of tuberculosis in cattle and giving information concerning the procedure with this disease. It is also recommended that the importation of animals into reacting herds of cattle shall not take place until after a sufficient time has elapsed to make sure that the nonreacting cattle are healthy. A plan is proposed for the use of tags for marking healthy and tuberculous cattle so that no mistake can be made. It is also urged that the repeated use of tuberculin in attempts to immunize cattle be prohibited.

The tuberculin test of hogs and some methods of their infection with

tuberculosis, E. C. SCHROEDER and J. R. MOHLER (*U. S. Dept. Agr., Bur. Anim. Indus. Bul.* 88, pp. 51).—On account of the prevalence of tuberculosis among hogs in certain localities it is often desirable to use the tuberculin test in separating affected from healthy animals. In the studies which were made by the authors, 12 hogs were infected with tuberculosis by feeding them milk to which tubercle bacilli had been added. Four hogs were allowed to follow cattle affected with tuberculosis, 4 more followed cattle which received tubercle bacilli in their drinking water daily, and 12 hogs were infected with tuberculosis by subcutaneous inoculation.

A study was made of the normal temperature of hogs, and it appears that the temperature of fat hogs is higher than that of poor ones. It was found that the temperature of hogs rises rapidly and to the extent of 3° or 4° as a result of driving or excitement. It became necessary, therefore, to place each hog in a rectangular crate about 12 hours before taking the temperature and to keep them thus confined until the tuberculin test was completed. The temperatures were taken hourly for 16 to 23 hours before injection and for from 30 to 40 hours after injection. The dose of tuberculin was $\frac{1}{2}$ cc. per 100 lbs. of live weight. Of 58 hogs tested with tuberculin, 26 reacted and were found to be tuberculous upon post-mortem examination. In nearly every instance the temperature of tuberculous hogs reached 105° F. after injection.

The reaction to tuberculin begins within 7 hours, reaches a maximum about 14 hours after injection, and continues for 16 hours later. Since it was found that the temperature of hogs might be elevated as much as 4.4° F. by walking 4 minutes at a slow pace, it is obvious that time and labor will be wasted in making a tuberculin test with hogs unless precautions are taken to prevent excitement and worry in the animals. When these precautions are observed, the tuberculin test is practically as reliable with hogs as with cattle.

The temperature and autopsy records are presented in detail in a tabular form. With regard to the method of infection of hogs it was found that the feces of tuberculous cattle or cattle which received tubercle bacilli in their food are highly infectious for hogs which follow them in the feed lot. Hogs readily contract tuberculosis in this way; in fact their susceptibility through exposure to infected food is much greater than that of guinea pigs.

Tuberculin in guinea pigs artificially infected with tuberculosis, P. STAZZI (*Clin. Vet. [Milan]*, 29 (1906), No. 32, pp. 773-782, pl. 1).—During the author's investigations it appeared that guinea pigs rendered tuberculous by artificial inoculation show a reaction to tuberculin which becomes more pronounced as the disease progresses. In guinea pigs which show an unusual susceptibility to tuberculin this reagent may cause parenchymous congestion and hemorrhage. In the author's opinion the striking sensitiveness of guinea pigs to tuberculin in advanced stages of tuberculosis is susceptible to several interpretations, but the simplest one is that with the progress of the disease the amount of tuberculin already in the animal body becomes greater until a point is reached where any additional amount can not be endured.

The resistance of tuberculin toward light, H. JANSEN (*Centbl. Bakt. [etc.]*, 1. Abt., Orig., 41 (1906), No. 7, pp. 775-779, fig. 1).—A test was made of the effect of intensive illumination upon tubercle bacilli killed by light and upon tuberculin.

It was found that the illumination had no influence whatever upon dead tubercle bacilli. The specific toxin of the tubercle bacillus as found in tuberculin is very resistant to light and intense illumination for 2 hours appeared to have no effect upon it.

The simultaneous method of vaccination against anthrax, G. SOBERNHEIM (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 1 (1906), No. 6, pp. 442-450).—The use of serum and virus simultaneously, according to the method devised by the author, has been extensively tested on all kinds of domestic animals susceptible to anthrax, and the results obtained indicate that the method is a reliable and satisfactory one.

Immunization against anthrax by the method of Sobernheim, A. STADIE (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 1 (1906), No. 2-3, pp. 127-143).—The Sobernheim and Pasteur methods of immunizing animals against anthrax were directly compared. In a case of two sheep treated by the Sobernheim method and subsequently tested with virulent cultures 4 weeks after the immunizing process, both animals died of anthrax within 5 days.

On the basis of this experiment and others with calves, the author comes to the conclusion that Sobernheim's method possesses no superiority over the Pasteur method.

The effect of sterile animal decomposition products on anthrax bacilli, C. SCHIFF (*Deut. Tierärztl. Wchenschr.*, 14 (1906), No. 34, pp. 405-410).—In the experiments reported in this paper it was found that the fluid obtained from decomposing animal bodies exercises a bactericidal effect upon anthrax bacilli, even after it has been filtered so as to be free from bacteria. This effect of the decomposition fluid is not destroyed by heating to a temperature of 100° C. Anthrax spores, however, are not affected. The gases produced during decomposition of animal bodies have no effect upon the anthrax bacillus.

Inoculation with blood from animals immunized against rinderpest by the use of bile, E. RASSAU (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 1 (1906), No. 4-5, pp. 383-388).—Attention is called to the danger of using the blood of immunized animals for vaccination against rinderpest in the regions where Texas fever prevails. If such blood is used Texas fever may be transmitted to the vaccinated animals. The author states that the boundary of the region in which Texas fever occurs in South Africa is not so well defined as is the case in the United States, Paraguay, and the Argentine.

An outbreak of redwater (*Rhodesian Agr. Jour.*, 3 (1906), No. 5, pp. 529-531).—In studying an outbreak of this disease it was noted that the African coast fever was not present and that the usual blood parasite was to be demonstrated in all cases.

It appears that stabled calves may be removed to infected areas in winter with impunity, for the reason that infestation with ticks takes place gradually as spring opens.

Some unusual host relations of the Texas fever tick, B. H. RANSOM (*U. S. Dept. Agr., Bur. Anim. Indus. Circ.* 98, pp. 8).—Ordinarily the Texas fever tick passes its whole life from the larval to the adult condition upon one animal, where it undergoes two molts. Other ticks closely related to the Texas fever tick differ considerably in their life history, so that a number of possible schemes of host relations may be formulated for ticks as a whole.

Experiments undertaken by the author indicate that some variations may occur in the ordinary programme as laid down for the Texas fever tick. For example, ticks removed from the host just after the first molt will develop to the adult stage if placed upon another animal within 24 hours after removal. Ticks may also be removed from one animal to another after the second molt without causing any disturbance in their life history. Ticks removed from their host just before the second molt were found to be able to molt and live unattached to any host for 2 weeks. Moreover, Texas fever ticks will attach them-

selves in a larval condition not only to cattle, horses, mules, and jacks, but also to cats and dogs.

By way of comparison notes were given on the known facts in the life history of the ticks which carry African coast fever and European piroplasmiasis. In a continuation of this study an investigation will be made to determine whether the Texas fever tick is able to transmit the disease in other than the larval stage, whether other species of ticks may transmit Texas fever, and whether other animals than cattle and horses may be concerned in the dissemination of the ticks.

Vaccination for septic pneumonia in calves, GOLDBERGER (*Berlin, Tierärztl. Wechschr.*, 1906, No. 27, pp. 507, 508).—Septic pneumonia occurred in an unusually serious outbreak causing death of every calf on the estate in question within a few days after birth. The author began the use of a vaccination method applied within one day after birth and in this way prevented the further development of the disease.

Lorenz's organism of pneumonia, HOBSTETTER (*Ztschr. Veterinärk.*, 18 (1906), No. 27, pp. 303-305).—The author undertook a study of a number of cases of pneumonia in horses for the purpose of determining whether the organism described by Lorenz was present in or on the skin. All tests gave negative results. Not a trace of the organism in question was found in numerous pieces of the skin taken for examination, neither was the author able to find an organism of pneumonia in the dust removed by currying infected horses.

The transmission of pleuro-pneumonia to sheep and goats, E. DUJARDIN-BEAUMETZ (*Ann. Inst. Pasteur*, 20 (1906), No. 6, pp. 417-448).—Pleuro-pneumonia is commonly considered as affecting only cattle. During the author's experiments, however, he found it possible to transmit the disease to sheep and goats in a number of cases. There seemed to be no difference in the susceptibility of sheep and goats to inoculation. When the udder of sheep was inoculated, only slight inflammation was produced, but the milk contained the virus of pleuro-pneumonia, as was shown by repeated observations.

Etiology, pathology, morbid anatomy, and other matters connected with the diseases of sheep known as louping ill and braxy, D. J. HAMILTON, J. M. MCCALL, and E. G. WHEELER (*London: Bd. Agr. and Fisheries*, 1906, pts. 1, pp. 36; 2, pp. 342, pts. 8, figs. 29; 3, pp. 13).—The authors were appointed as a committee to investigate louping ill and braxy in sheep.

The symptoms of these 2 diseases are somewhat similar and the diseases are sometimes confused by those who have had little experience with them. Louping ill is confined to the British Isles, being most prevalent in the west and south of Scotland and north of England. The mortality varies from 20 to 50 per cent. Sheep of all ages are susceptible, and occasionally cattle and pigs or even geese are affected. In acute cases the symptoms are those of septicemia, and the animals live only a few hours, while in chronic cases the course of the disease may be extended for a few weeks.

Braxy is known in various parts of Great Britain, the Faröes, Ireland, and Norway. The death rate is usually 20 per cent, and at times the disease may cause almost total annihilation of a flock of sheep. The disease runs a very rapid course.

During the investigation of the committee an elaborate series of observations were made on the organisms which produce louping ill and braxy. In all cases of louping ill an organism is found in the intestines which is referred to under the name *Bacillus choreæ paralytica oris*. Similarly in braxy a specific organism appeared to be the cause of the disease, and ticks apparently have no definite connection with either louping ill or braxy. No success attended the

numerous experiments of the committee in immunizing sheep to either louping ill or braxy by subcutaneous inoculations of cultures of the bacterial organisms. Treatment by means of drenching, however, was very satisfactory. This consists in adding cultures of the organisms in question to the water which is given the sheep, and in order to be successful the treatment must be applied at seasons when sheep are naturally somewhat resistant to the diseases. It is believed that this method of drenching may prove successful in the case of other diseases.

Experiments in vaccination against contagious agalactia in sheep and goats, A. CELLI and D. DE BLASI (*Clin. Vet. [Milan]*, 29 (1906), No. 32, pp. 769-773).—A test was made to determine the effect of virus filtered and heated to temperatures ranging from 40 to 45° C. for a period of half an hour in vaccinating sheep and goats against contagious agalactia. It appeared, during the investigation of the authors, that goats and sheep could be completely protected in the majority of cases against subsequent infection by treatment with virus previously heated so as to attenuate it. The use of milk from cases of the disease previously rendered noninfectious gives no benefit, since such milk appears to be without immunizing power.

Malarial catarrhal fever or bluetongue of sheep, E. M. JARVIS (*Rhodesian Agr. Jour.*, 3 (1906), No. 5, pp. 513-516).—Bluetongue has been studied by the author during the past 5 years. The symptoms vary considerably, but there is ordinarily a high fever and inflammation of the mucous membrane of the mouth, which becomes reddish or occasionally blue. The mortality is not very high and the post-mortem findings are not striking. If the disease occurs in a virulent form it may be controlled by vaccination.

The benefits of sheep dipping, F. S. H. BALDREY (*Agr. Jour. India*, 1 (1906), No. 3, pp. 201-204).—The regular periodical dipping of sheep is desirable and in many cases necessary not only in the control of sheep scab but in destroying other animal parasites which may be found in the wool and on the skin of sheep.

Pseudo-tuberculosis of sheep and its relationship to echinococci (*Deut. Tierärztl. Wchenschr.*, 14 (1906), No. 29, pp. 346-348, figs. 2).—The micro-organism of this disease was isolated and studied in pure cultures. A number of experimental inoculations were also made, and the author gave considerable attention to a study of the distribution of the organism in the infected animals. It appeared that in certain instances the bacterial organism was carried through the cells of the intestines through the agency of echinococci carrying bacilli.

The method of vaccination for swine erysipelas, PFLANZ (*Deut. Tierärztl. Wchenschr.*, 14 (1906), No. 27, pp. 321, 322, figs. 3).—With an ordinary hypodermic syringe considerable trouble is experienced in vaccinating hogs without hard work and the probability of becoming badly soiled. The author uses a syringe furnished with a rubber tube one-half to one and a half meters long. As soon as the needle is inserted into the skin back of the ear the hog may run about the pen somewhat but the length of the tube enables the operator to prevent the needle from being withdrawn until the serum has been injected.

A pulmonary disease of rabbits due to bacilli resembling those of swine plague, H. SELTER (*Centbl. Bakl. [etc.]*, 1. Abt., Orig., 41 (1906), No. 4, pp. 432-435).—An outbreak of a pulmonary disease occurred among rabbits and was studied with the result that an organism was found which closely resembled that of swine plague and must be referred to this group of bacilli. The exact relationship between the two is not yet determined.

Atelectasis of the lungs and its relation to swine plague, SIMADER (*Berlin. Tierärztl. Wchuschr.*, 1906, No. 24, pp. 445-450, fig. 1).—A careful study was made of the occurrence of atelectasis in the lungs of swine and other animals for the purpose of determining the conditions under which this phenomenon appears and its possible relation to the development of swine plague.

The author found that atelectasis appears in various forms, some of them being congenital and others appearing later. Atelectasis occurs frequently in all animals used for food and is usually of congenital origin. The history of cases of atelectasis varies greatly. The solid portions of the lungs thus affected may become expanded by violent inspiration of air, and a normal condition may thus be brought about. Otherwise the affected part may show a pronounced atrophy in the course of time.

The author believes that atelectasis has absolutely nothing to do with swine plague except in so far as the bacilli of swine plague may find a more favorable place for growth in the atelectatic parts of the lungs.

Notes on the etiology of swine plague, A. STADIE (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 1 (1906), No. 4-5, pp. 376-381).—According to the author's experiments, the filtered fluid obtained from the lungs of hogs affected with swine plague exercises no specific effect. In a number of experiments, during which pigs were artificially inoculated with *Bacillus pyogenes suis*, it was found that the disease thus produced was not readily transmitted from one animal to another. In fact, no such transmission took place during the period of 3 weeks in which inoculated and healthy animals were kept in close contact.

Immunization toward hog cholera by the aid of bacterial extracts, J. CITRON (*Ztschr. Hyg. u. Infektionskrank.*, 53 (1906), No. 3, pp. 515-553).—In a long series of experiments carried on by the author it appeared that immunity produced by aggressins and bacterial extracts is of practically the same nature and duration. Aggressins and bacterial extracts appear to be serviceable under the same conditions and likewise fail at the same points. It is shown conclusively that the immunization produced by this method is due to bacterial extracts and not to the bacterial bodies themselves. This point was demonstrated by positive results with the use of extracts and by negative results from the use of bacterial bodies after the extracts had been removed. The author believes, however, that immunization against hog cholera by means of aggressins or bacterial extracts is very unreliable as compared with results obtained by vaccination with mouse typhoid.

Active and passive immunization toward hog cholera, M. I'RETTNER (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 1 (1906), No. 6, pp. 451-474).—In an extensive series of experiments with mice, rabbits, guinea pigs, and swine it was found possible to produce a high degree of active immunity by the use of exudates free from the bacillus of hog cholera. Serum obtained from actively immunized animals may be depended upon to produce a fair degree of passive immunity when injected into other animals.

Feeding experiments with feces containing trichinæ, H. M. HÖYBERG (*Centbl. Bakt. [etc.]*, 1. Abt., Orig., 41 (1906), No. 2, pp. 210, 211).—The commonly accepted statement regarding the transmission of trichinæ is that infection takes place only after taking muscle trichinæ into the stomach and that intestinal trichinæ brought in contact with the digestive juices of another animal are destroyed. The author infected a number of brown rats by feeding them trichinous pork and subsequently used the intestinal contents of these infested rats in feeding other rats. As a result of these experiments 4 out of 5 rats became infected and it appears, therefore, that intestinal trichinæ may be in a position to infect other animals without having previously passed a period

of their life in muscle tissue. Further experiments along this line will be carried on with hogs.

The behavior of the glanders bacillus in urine and its excretion through the kidneys, G. CAGNETTO (*Centbl. Bakt. [etc.], I. Abt., Orig., 41 (1906), Nos. 1, pp. 21-31; 2, pp. 173-185*).—The literature relating to the behavior of the glanders bacillus under various conditions is critically reviewed.

The author made extended observations on the action of the urine of healthy and glanderous horses upon the glanders bacillus and found that the urine from glanderous horses exercises a remarkably rapid attenuating effect upon the bacillus. In many cases the bacillus became nonvirulent within a few hours. The general statement is made that in the urine of normal horses, jacks, cats, and man, the glanders bacillus remains pathogenic for from 30 hours to 4 days, but begins to show various morphological changes before it becomes nonvirulent. In the urine of glanderous horses, however, the bacillus loses its virulence entirely within 20 hours.

With regard to the frequency of the excretion of glanderous bacilli by the kidneys the author found that in only 2 out of 50 glanderous horses, among which he made observations, was the urine virulent for laboratory animals.

The control of glanders and the use of mallein, M. SCHLEGEL (*Die Rotz- bekämpfung und die Malleinprobe beim Pferde. Stuttgart: F. Enke, 1905, pp. IV+88*).—During the author's investigations which extended over a period of several years and involved the use of mallein on more than 1,000 horses, particular attention was given to the nature of the reaction and the reliability of the mallein test as giving an indication of the proper disposal of the reacting horses.

The results obtained by the author in his various mallein tests are presented in a tabular form and clinical notes are given on many of the most interesting cases. As a result of this study the author recommends that in the control of glanders all animals in which the disease may be diagnosed by clinical symptoms should be killed immediately. All animals which have come in contact with these cases or which are otherwise to be suspected for any reason should be tested with mallein and of this number all which react in a typical manner should be killed and the premises thoroughly disinfected. Those horses which did not react should be removed to buildings free from infection after a previous disinfection of the hoofs or other parts which may have come in contact with infection.

Horses which react in an atypical manner and those which do not give a reaction but which are to be suspected in any way on account of clinical appearances should be quarantined and tested again after 1 month at which time the reactors and nonreactors are to be treated as just recommended.

Four cases of tetanus with recovery, M. MOLE (*Vet. Rec., 19 (1906), No. 946, pp. 115, 116*).—Details are given regarding the symptoms of 4 cases of tetanus which were treated with antitetanus serum. Recovery took place in all cases, but after improvement appears the author recommends a dose of carbolic acid. It is suggested that the usual dose of 10 cc. be divided and given twice per day.

Infectious inflammation of the spinal cord in the horse, M. SCHLEGEL (*Berlin, Tierärztl. Wchnschr., 1906, No. 25, pp. 463-475, pl. 1*).—The author has had occasion to study this disease for a number of years in several localities in Germany and presents the results of his investigations in considerable detail.

The disease affects horses of all ages and both sexes. It is due to *Streptococcus melanogenes* and is sometimes referred to as a streptococcic septicemia. In a majority of cases the disease ends fatally within a few days, but occa-

sionally it may run a chronic course extending over 1 to 3 weeks. Horses affected with this disease become emaciated and anemic. The blood appears to be paler than usual and does not readily coagulate. The liver is greatly enlarged, hyperemic, and softened. The chief lesions in the spinal cord are seen in the pia mater. No satisfactory treatment has been devised, but the disease may be prevented from spreading by the use of strict quarantine measures.

Negri's corpuscles and infection with rabies, A. BONGIOVANNI (*Centbl. Bakt. [etc.], 1. Abt., Orig., 41 (1906), No. 3, pp. 343-352*).—In the author's experiments with laboratory animals, chiefly rabbits, he was quite unable to find Negri's corpuscles in any part of the nervous system of any animal after infection with rabies, either from laboratory or street virus. It would appear, therefore, that complete reliance can not be placed on Negri's corpuscles in the diagnosis of this disease.

The cause of roup, R. MULLER (*Centbl. Bakt. (etc.), 1. Abt., Orig., 41 (1906), Nos. 4, pp. 423-426; 5, pp. 515-523; 6, pp. 621-628*).—The author made a bacteriological study of several cases of roup in fowls. A bacillus was found that grows readily on blood-agar and which appears to be closely related to the bacillus of human diphtheria. Notes are given on the behavior of this bacillus when cultivated on different kinds of nutrient medium.

By means of inoculation experiments the author found it possible to produce roup artificially in laboratory animals, with symptoms essentially the same as are observed in spontaneous cases of the disease. The bacillus of roup appears not to form a toxin. It may be destroyed by subjection to a temperature of 58° C. for one-half hour. The bacilli, however, are quite resistant to ordinary disinfectants, and a thorough use of such materials is required in order to eradicate an infection with this disease.

Spirillosis of fowls, LEVADITI and MANOUELIAN (*Ann. Inst. Pasteur, 20 (1906), No. 7, pp. 593-600*).—A detailed study was made of the pathological histology of spirillosis as produced in fowls by *Spirillum gallinarum*.

It appears from this study that the septicemia caused by the organism in question is not due entirely to the multiplication of micro-organisms in the blood, but that the parasite infests a number of glandular tissues, including the liver and spleen. In the presence of *Treponema pallidum* the micro-organism appears not to penetrate into the protoplasm of the cells. The spirillum which causes the disease in question is capable of entering and infecting the eggs in the ovary. A favorable turn of the disease at the crisis is due to the destruction of the spirillum by the large leucocytes of the spleen and liver.

Do the bacteria of fowl cholera occur in the intestines of healthy geese? R. OSTERTAG and P. ACKERMANN (*Ztschr. Infektionskrank. u. Hyg. Haustiere, 1 (1906), No. 6, pp. 431-441, fig. 1*).—It is sometimes believed that fowl cholera may break out as the result of hardships suffered by the fowls and that therefore the organism of the disease must have been present in the alimentary tract during apparent health. This matter was investigated by the authors with the result that the bacteria of fowl cholera were not found in the intestines of healthy geese or fowls. The disease did not develop in birds which were kept in cages for 5 or 6 days under unfavorable conditions and without food or water.

The incubation period of the disease and the length of the course of fowl cholera varies considerably. Geese may die as the result of eating one meal containing fowl cholera bacilli, and death may take place in from 2 to 10 days. The incubation period in geese is usually 1 to 2 days and in chickens 4 to 9 days.

The disinfection of stables, C. M. HARING (*California Sta. Circ.* 19, pp. 3).—The purposes and meaning of disinfection are briefly discussed and suggestions are made regarding sanitary methods of cleaning and disinfecting stables.

RURAL ENGINEERING.

History of rural engineering, Chaldea and Assyria, M. RINGELMANN (*Ann. Inst. Nat. Agron.*, 2. ser., 5 (1906), No. 1, pp. 85-139, figs. 52).—In this article the author discusses the agricultural machines and rural engineering works of the ancients so far as knowledge concerning them can be gained from inscriptions, relics, and other sources of information. He treats of their agricultural implements, such as plows, hand tools, grinding mills, etc., their methods of using them, their means of transportation by sledges, wheeled vehicles, and rafts of inflated sheepskins, together with a description of the form of harness used on horses and oxen, and the status of the slaves, by whom agricultural operations were carried on.

Irrigated agriculture in Egypt in ancient times, A. DE CERIS (*Jour. Agr. Prat.*, n. ser., 11 (1906), No. 23-24, pp. 720-725, figs. 7).—This is a chapter from A Study of the History of Rural Engineering, by M. Ringelmann, reviewed above, in which, from an exhaustive study of Egyptian documents and other data, he has been able to determine in great detail the system of irrigation and crop culture practiced by the ancient Egyptians.

The author finds that "after having protected the valley against the floods of the Nile by insubmergible dikes, parallel to the river, they had increased the zone capable of submersion by a number of canals, of which it is still possible to find the remains. This indicates to what degree the departments of rural engineering relative to embankments, basins of inundation, and drainage had been carried."

Irrigation in Montana, S. FORTIER, A. P. STOVER, and J. S. BAKER (*U. S. Dept. Agr., Office Expt. Stas. Bul.* 172, pp. 108, figs. 18).—The object of this bulletin is to present the present status of irrigation in Montana in its engineering, agricultural, and legal aspects.

The method employed was to study these various features in typical sections, rather than to attempt to cover the whole State. In their study of conditions in Montana the authors paid special attention to the means of bringing about the more economical use of the water supply, which would make possible the largest development of the State's agriculture.

The most conspicuous sources of waste were poorly constructed ditches, poorly prepared fields, careless use of water, and lack of public supervision of the acquirement of rights and of the distribution of water. Owing to the large supply of water, as compared with the present demand, there has been an indifference to these things, especially the need of legislation creating such public control as will insure the peaceable enjoyment of the rights to water, which is necessary to the highest development. In his conclusions Professor Fortier makes certain recommendations regarding such legislation.

Punjab irrigation branch papers (*Punjab Irrig. Branch Papers*, No. 11, pp. 109, *dyms.* 7).—This bulletin consists of three reports, (1) Lining of Water Courses for Prevention of Absorption; (2) Waste of Water by Cultivators in Irrigating their Fields; (3) Number of Waterings required for Wheat Crops.

The experiments on ditch lining were carried on in parallel trenches, 24 ft. long, the loss by seepage being read with hook gauges. Evaporation was measured separately and allowed for. Crude oil, cement, lime, coal tar, and clay puddle were applied in various combinations. Oil was found to be most

effective, reducing the loss over 90 per cent in some cases. Cement and coal tar are next in efficiency, while lime and clay puddle are least effective, the latter reducing seepage about one-half. Hand methods only were employed, the lining being mixed thin and spread from a pail handled by one man. Owing partly to the tendency of thin cement mortar to settle and to its great weight, it was found to be much more expensive to apply than the oil, which runs freely at a moderate temperature. Oil and tar were applied to a depth of $\frac{1}{32}$ in. for each coat, being dusted over with damp earth at once and protected by a backfilling of earth to a depth of 8 to 18 in. Neat cement was applied $\frac{3}{4}$ to $\frac{1}{16}$ in. thick for each coat, two coats being used. Lime paste was put on in one coat $\frac{1}{8}$ in. thick. Clay was mixed thin and spread by hand from pans in three layers, giving a total thickness of $\frac{1}{4}$ in.

All the linings were covered with a foot or more of earth which was settled with water, after which the channel was reexcavated to its desired size. It is proposed to continue these experiments for several years, as the most important consideration is the durability of the linings used.

The experiments to determine waste were made on grain fields, experimental plats being selected adjoining fields irrigated in the usual manner. The only difference in the method of application lay in the use of smaller checks on the experimental plats. The excess used by the cultivators was 41 per cent for the first watering, 24 per cent for the second, 20 per cent for the third, and 30 per cent for the last. The total depth applied was 0.81 ft. on the plats and 1.05 ft. in the fields. The yield of grain was not materially different on account of the amount of water applied.

The experiments to determine the number of irrigations for wheat showed that three irrigations would produce a full crop and that more than four were a positive injury.

An investigation of the natural basis of irrigation farming in North America, A. GOLF (*Inaug. Diss., Univ. Halle-Wittenberg, 1903, pp. 87*).—A study of the topography, climate, soil, and water resources of the arid region of the United States in their relation to irrigation.

Design and construction of small irrigation canals, W. L. STRANGE (*Transvaal Dept. Irrig. and Water Supply Bul. 2, pp. 75, pls. 39*).—This is a series of notes dealing with the subject in a brief but comprehensive way, numerous and valuable practical suggestions being given. In an appendix are included tables of canal discharges based on Bazin's formula and a number of drawings of canal structures in plan, elevation, and section.

The utility of wind power in agriculture (*Impl. and Mach. Rev., 32 (1906), No. 377, p. 555*).—In commenting upon the uses to which wind power can be put it is suggested that in sawing wood by the aid of a windmill a 24-in. saw blade be used with a 12 to 14 ft. wheel and a 28-in. with a 16-ft. wheel. It is asserted that a 12-ft. windmill will furnish sufficient power to saw 12 to 15 cords per day, and that the same mill in a fair wind will grind 12 to 15 bu. of grain per hour.

The demand for windmills in British South Africa (*Masch. Ztg., 4 (1906), No. 10, p. 117*).—For several years past there has been an agitation in South Africa to undertake the irrigation of extensive tracts of land in that country. Owing to a general business depression these plans have failed of execution, but an impetus has been given to private enterprise by which some excellent results have been obtained. In this connection there is a constant demand for windmills, most of which are imported from the United States.

The mills which have been sent are, according to the writer, far from being modern in design, of faulty construction, and unsuited to the needs of the

country. Mills which disappeared from our markets 20 years ago are yet being sold in South Africa. Some of these are so poorly built that it requires a strong wind to turn them; in others the towers are so weak that they are unable to resist storms. The mill for the irrigation of a small farm in South Africa must be designed to lift enough water from a depth of 25 to 30 ft. to cover daily 1 acre of land with water to a depth of 3 in. Further considerations are ease of erection, simplicity of mechanism, and automatic regulation as far as possible.

The usual wind velocity observed along the seacoast and in exposed places is 12 to 18 miles per hour; in the interior, 8 miles per hour.

The difficulty of surveying deep bore holes (*Engin. Rec.*, 54 (1906), No. 4, p. 87).—A method is described in which the difficulty is surmounted by the use of photography.

Fourth annual report of the State board of public roads of the State of Rhode Island, 1906 (*Ann. Rpt. Bd. Pub. Roads R. I.*, 4 (1906), pp. 37, pls. 39).—An account of the work accomplished and in progress under the Rhode Island "good roads law."

The road drag for improving earth roads (*Engin. News*, 55 (1906), No. 24, pp. 666, 667, figs. 2).—The Illinois Highway Commission recommends a light road drag for improving the condition of muddy roads; the lighter and more simple the drag, the greater its effectiveness.

A form recommended is that consisting of two split logs 10 and 12 in. in diameter and 9 ft. long, held parallel to each other and about 3 ft. apart by suitable braces. A chain is attached with a short and long hitch so that the drag travels at about 45° to the direction of the road. The flat surface of the split logs is on the forward side, and the lower edge should be protected by a strip of wagon tire. More complicated forms of drags are shown and the theory of road dragging explained.

Roads and tires (*Engin. Rec.*, 54 (1906), No. 4, p. 87).—Reference is made to the increasing difficulty in designing and maintaining good roads suitable for all kinds of traffic. It is pointed out that while a smooth, hard surface, such as a steel roadway, might be ideal for the use of heavy freight traffic, it would be poorly adapted for the rubber tires of motor cars, which slip on smooth wet surfaces. Although a macadam pavement is excellent in affording a bite or grip for traction purposes, it is very rapidly worn out, since the binding material is swept out as dust or mud under the action of motor-car tires. It is suggested that the solution of the difficulty may be found in elastic but solid tired wheels, a more resilient roadbed, or a combination of both.

The application of electric motors to agricultural operations, F. KOESTER (*Engin. Mag.*, 31 (1906), No. 5, pp. 655-667, figs. 15).—An article descriptive of the use of electric power in agricultural operations on farms in Europe, with some arguments as to its advantages, mainly from the standpoint of ease of distribution and lessened fire hazard. Little data are given as to economy, but this may well be questioned for any but the most extensive undertakings in the light of the fact that the first cost of a plow system averages about \$10,000.

Denatured alcohol, its use in Germany and France (*Daily Consular and Trade Rpts.* [U. S.], 1906, No. 2662, pp. 1-11).—An article prepared by the consuls-general of Berlin and Paris in response to the generally expressed desire for information on the subject.

Statistics are given showing that in Germany a large proportion of the alcohol output is derived from potatoes, the production of which for this purpose is the chief support of many of the farming regions remote from business centers.

It is found that it requires 1.26 bu. of potatoes to produce 1 gal. of pure alcohol. The cost is difficult of determination, depending upon a variety of factors such as the size of distillery, efficiency of apparatus and methods, and upon the disposal of by-products. Statistics are given relating to the use of alcohol for drinking and industrial purposes, to the use of incompletely denatured alcohol, and the consumption of tax-free alcohol. The methods of denaturing are discussed, and systems of distribution and government control described.

In the case of France, similar information is given, with description of the methods pursued by the Government in the attempt to extend the use of the denatured product. Its use seems not to have been attended with much success as a fuel, either for lighting or power. Although it was found by experiment to be a pure and economical fuel, it required a special type of engine and was found to erode valves and cylinder surfaces. When used in lamps it was attended with no success whatever, due probably to the ineffective character of the apparatus.

Royal agricultural show (*Engineer* [London], 102 (1906), No. 2636, pp. 16-18, figs. 8).—A description of various types of road locomotives and power machinery exhibited at the Derby show. A gas-producer test is mentioned in which the consumption of anthracite pea coal was 0.785 lb. per brake horsepower per hour.

Cylinder cooling in the alcohol engine (*Engin. Rec.*, 54 (1906), No. 4, p. 87).—It is asserted that the flame of burning alcohol radiates heat less rapidly than that of gasoline and that, therefore, the problem of cooling the cylinders of alcohol motors will be less difficult than with those using gasoline.

The efficiency of suction gas plants: Remarkable results (*Impl. and Mach. Rev.*, 32 (1906), No. 374, pp. 188, 189).—The saving effected by the use of these plants and gas engines over the old steam plants, as given by various users, amounts to 75 to 80 per cent.

Farming by steam power, J. L. DONAHUE (*Threshermen's Rev.*, 15 (1906), No. 9, p. 7).—A problem in connection with farming in the semiarid lands of Colorado and New Mexico is the breaking up of the largest possible area in the limited time during the early spring when the ground is in condition to plow. It is equally important that this ground be packed and harrowed simultaneously with the plowing in order to conserve the soil moisture. To solve this problem and at the same time reduce the expense to the minimum, steam power has been employed with considerable success. A 32-horsepower engine pulled 8 14-in. moldboard plows, 2 corrugated iron rollers, 2 harrows, and 2 seed drills, by which it was possible to plant 12 acres in peas per day of 10 hours, at an expense of \$25 per day. Without the seeders 20 acres could be plowed, packed, and harrowed per day at an expense of \$1.25 per acre. With ground in less favorable condition the expense is greater.

The chief factors of cost in operation are coal and the hauling of water. It is suggested that the use of the alcohol engine may reduce the probable cost of operation to 50 cts. per acre.

Steam plows used (*Farm Machinery*, 1906, No. 767, p. 24).—It is asserted that by the use of steam plows and other labor-saving devices an increase in yield of sugar cane of 50 per cent has been effected in Trinidad, thus assuring the continuance of an industry which was in danger of becoming extinct through the effects of competition of Cuba and Porto Rico.

The draft of plows (*Threshermen's Rev.*, 15 (1906), No. 8, p. 20).—In an article copied from the *Country Gentleman* tables are compiled from the results of draft trials made in England and this country, which show the total number of

pounds required to pull a 14-in. plow cutting furrows of different widths and depths, together with the horsepower required at a rate of movement of 2½ miles per hour.

Stone-gathering machines, W. L. SUMMERS (*Jour. Dept. Agr. So. Aust.*, 9 (1906), No. 12, pp. 786, 787).—The writer describes the efforts being made in South Australia to evolve an effective machine which would remove loose stumps and stones from cultivable land, thereby reducing the cost of clearing. Although prizes were offered and several trials held, no machine has yet been designed which will meet the requirements.

A machine for picking cotton (*Queensland Agr. Jour.*, 17 (1906), No. 2, pp. 106-108, pls. 2).—The construction, operation, and efficiency of a cotton-picking machine invented by George A. Lowry are discussed.

Implements and machinery at the Suffolk show (*Impl. and Mach. Rcv.*, 32 (1906), No. 375, pp. 320-325, figs. 11).—The results of tests of a large number of various agricultural tools are given, one trial of especial interest being in the showing made by a 1½-ton tractor driven by a petrol or paraffin motor. This machine plowed an acre of light dry soil in 2½ hours, using 6 gal. of petrol and hauling a 3-furrow plow. The same machine subsequently operated a thrashing machine, pulled in turn a 4½-ton load, a 7-tine cultivator, and two 6-ft. mowers.

Some observations in the farm machine and implement section of the D. L. G. exhibition at Berlin-Schöneberg, G. KÜHNE (*Masch. Ztg.*, 4 (1906), No. 14, pp. 158-162).—A large number of tools, implements, and prime movers are mentioned and briefly described.

Of special interest among the latter are portable farm engines of from 8 to 26 horsepower, using producer gas on the suction principle. In this type of machine a gas producer, together with its scrubber and cooler, is made a part of the equipment, and with the engine is mounted on a strong four-wheeled wagon. The producer is adapted for anthracite coal or coke, as well as for peat, lignite, and wood. The coal consumption guaranteed is 0.6 kg. per horsepower hour for machines of from 8 to 12 horsepower.

In order to be able to compete with an equipment showing such notable economy manufacturers of steam engines are improving their designs, and a portable steam plant is described in which a 120-horsepower compound engine uses superheated steam and is provided with a condenser. By this equipment a saving of 40 per cent in fuel and 24 per cent in water consumption is effected over the same size machine using saturated steam.

A portable apparatus for farm-power purposes, in which is combined a gasoline engine, a set of storage batteries, and dynamo-motor, is described, as is also a small explosion motor in which there are certain novel features, notably a peculiar adjustable cylinder lining, making piston rings unnecessary.

Cement mortars, M. RINGELMANN (*Jour. Agr. Prat.*, n. ser., 12 (1906), No. 29, pp. 76-78).—Directions as to the proportions and methods of using mortars made with lime and hydraulic cements. When using quicklime the proportions recommended for masonry are: Lime, 1 volume; coarse sand, 2 to 2.5 volumes. For plaster, lime, 1 volume; medium or fine sand, 0.5 to 1 volume.

When using hydraulic or Portland cement the following is recommended: For ordinary masonry foundations, pavements, and plaster, use 1 volume of cement to 3.3 volumes of medium-sized river sand. For a very energetic mortar, use 1 volume of cement to 1.8 to 2.6 volumes of fine sand. For mortar to be used under water, use 1 volume of cement to 1.5 volumes medium river sand.

What the farmer can do with concrete, C. H. MILLER (*Farming*, 2 (1906), No. 2, pp. 11-13, figs. 14).—A popular article on the varied applications of con-

crete on the farm and the advantages following its use. Among the uses enumerated are foundations for houses, barns, and windmills, sidewalks, fence posts, water troughs, cisterns, tanks, and cesspools, floors for house and stable, stairs, well curbs, stalls, hog pens, chicken houses, cornercribs, ice houses, incubator cellars, mushroom cellars, hotbed frames, bridge abutments, chimneys, ventilators, and hitching posts.

Attention is called to the fact that in estimating on cost of concrete sufficient broken stone should be provided to fill the whole volume under estimate, since the cement and sand merely fill the voids in the broken stone.

A calculation is given of the cost of concrete posts, by which it is found that posts can be made for 14 cts. each. It is explained, however, that this low cost would be possible only when large numbers of posts are made.

Detailed bill of material for storage barn, sheds, feed lots, and other equipment for feeding experimental cattle in carload lots, H. W. MUMFORD and E. S. GOOD (*Illinois Sta. Circ. 103*, pp. 10).—A circular supplementing Bul. 110 of the Illinois Experiment Station and giving a detailed bill of material used in an experimental cattle-feeding plant.

RURAL ECONOMICS.

Changes in farm values, 1900-1905, G. K. HOLMES (*U. S. Dept. Agr., Bur. Statis. Bul. 43*, pp. 46).—Detailed statistical data on this subject are reported. The analysis, economic causes, and character of the results of this investigation have been previously noted from another source (*E. S. R.*, 18, p. 291).

Local conditions as affecting farm values, 1900-1905 (*U. S. Dept. Agr., Bur. Statis. Bul. 44*, pp. 88).—This bulletin consists of a partial reprint of an article from the Yearbook for 1905 (*E. S. R.*, p. 291) with selected statements from reports of 45,000 crop correspondents which show "the local conditions affecting values of farms in all parts of the country." The statements in general apply to medium-size farms, cover five years, and are grouped into counties and States under geographical divisions of the United States.

Report and scheme of national land settlement, H. R. HAGGARD (*London: Gort., 1905*, pp. VIII + 74).—The contents of this report have already been noted from another source (*E. S. R.*, 17, p. 816).

Agricultural settlements in British colonies (*London: Dept. Com. Agr. Settlements Brit. Colonies, 1906*, vols. 1, pp. IV + 41; 2, pp. IV + 381).—In January, 1905, Mr. H. R. Haggard was appointed special commissioner by the British government to investigate and report on the Salvation Army agricultural colonies established in the United States and at Hadleigh, England, with a view of suggesting some scheme for the settlement on agricultural land in the colonies of poor individuals and families from British cities (see above).

The report of the committee appointed by the British government to consider the plan suggested by the special commissioner is given in volume 1 of this publication, together with notes and memoranda by individual members of the committee bearing on certain phases of the subject. The report treats of the history of British agricultural colonies during the nineteenth century in Canada, South Africa, and Australia; outlines and discusses the scheme for agricultural settlements proposed by Mr. Haggard; reviews the evidence of witnesses who testified before the committee as to the respective merits of colonization and emigration; and enumerates the reasons why the scheme for national land settlement proposed by the commissioner should not

be adopted by the British government. While unable to indorse any plan of colonization at the present time, the committee makes several recommendations relative to the government giving financial aid to emigration societies, selection of colonies for emigrants, supervision of emigration, and the emigration of soldiers whose term of service has expired.

Volume 2 consists of a complete record of the evidence taken before the committee which forms the basis of the report, together with 23 appendices bearing upon various phases of emigration, agricultural statistics, colonization schemes, etc., a detailed analysis of the evidence, and an index.

Land settlement, agriculture, and live stock, E. G. STENBERG (*Statist. Reg. West. Aust., 1904, pt. 5, pp. 72, map 1*).—Statistics for the year 1904 in comparison with similar data for the years 1895 to 1904 are published from official governmental returns without comment.

The data relate to the occupation of land in Western Australia, areas open for selection, land improvements, and other subjects relating to land settlement; the areas under crops, total and average yields, kinds of field crops and fruits, cereal production, fertilizers, irrigation, dairying, poultry raising, bee raising, employment and wages of farm labor, prices of farm products, and related agricultural topics; and the number and classification of live stock, number slaughtered and lost from various causes, and the number and value of imports and exports of live stock.

The development of agriculture in Denmark, R. J. THOMPSON (*Jour. Roy. Statist. Soc., 69 (1906), No. 2, pp. 374-411*).—This is a paper read before the Royal Statistical Society of London in May, 1906.

Statistics are presented and discussed on the historic development in Denmark of systems of land tenure, size of holdings, cultivated areas, live stock, trade in agricultural produce, prices, cooperation, and labor, the data in general being compared with similar data relating to Great Britain. The present condition of agriculture in Denmark is said to be highly prosperous, and this prosperity is assigned to three causes, namely: (1) Land tenure, which has created a homogeneous farming community who, as owners of the soil, cultivate farms of moderate size; (2) education, which by means of elementary, technical, and adult continuation schools has produced the most enlightened peasantry in the world; and (3) cooperation, which by promoting the production and sale on a large scale of agricultural products for exportation abroad has fulfilled the aim of Danish agriculture.

Cooperative credit in Bengal, W. R. GOURLAY (*Agr. Jour. India, 1 (1906), No. 3, pp. 216-219*).—The author briefly describes the plan adopted by the imperial and provincial departments of agriculture of India in promoting agricultural credit banks in the provinces.

The system consists primarily in making village societies rather than individual peasants responsible for borrowing, disbursing, and collecting principal and interest on loans, which are advanced at rates ranging from 6 to 12½ per cent interest instead of from 25 to 50 per cent as charged by money lenders. There are at present 86 experimental village societies in Bengal, and more than 60 of these are said to be working on sound principles. The results, says the author, "show that we are on the road to a successful solution of the problem of financing agriculture." Notes are also given on the institution of banks for advancing seed grain to agriculturists.

Imports of farm and forest products, 1903-1905 (*U. S. Dept. Agr., Bur. Statist. Bul. 45, pp. 62*).—Detailed statements of imports of farm and forest products, including the countries from which consigned, are reported. The following table summarizes the value data:

Values of farm and forest products imported into the United States.

Kinds of imports.	Year ended June 30—			Total, 1903-1905.
	1903.	1904.	1905.	
Farm products.....	\$456,199,325	\$461,434,851	\$553,851,214	\$1,471,485,390
Forest products.....	71,478,022	79,619,296	92,680,555	243,777,873
Total.....	527,677,347	541,054,147	646,531,769	1,715,263,263

Exports of farm and forest products, 1903-1905 (*U. S. Dept. Agr., Bur. Statis. Bul. 46, pp. 72*).—Detailed statements of exports of farm and forest products, including the countries to which consigned, are reported. The following table summarizes the value data:

Values of farm and forest products exported from the United States.

Kinds of exports.	Year ended June 30—			Total, 1903-1905.
	1903.	1904.	1905.	
Farm products.....	\$878,480,557	\$859,160,264	\$826,904,777	\$2,564,545,598
Forest products.....	58,281,124	70,085,789	63,199,348	191,566,261
Total.....	936,761,681	929,246,053	890,104,125	2,756,111,859

Trade with noncontiguous possessions in farm and forest products, 1903-1905 (*U. S. Dept. Agr., Bur. Statis. Bul. 47, pp. 45*).—The value of farm and forest products shipped from the United States to Porto Rico, Alaska, Hawaii, Philippine Islands, Tutuila, Midway Islands, and Guam in 1905 was \$15,851,726, as compared with a value of \$15,154,837 in 1904; while the shipments from noncontiguous possessions to the United States amounted in value to \$61,699,925 in 1905, as compared with \$46,898,012 in 1904. Data as to the quantity, value, and destination of the various products are reported in detail.

Retail prices of food, 1890 to 1905 (*Bur. of Labor [U. S.] Bul. 65, pp. 171-316*).—Statistical data of the retail prices of 30 staple foods secured in the principal industrial centers of 40 States, including the District of Columbia, are reported. For the United States as a whole the average cost of food per family ranged from \$296.76 in 1896, the year of lowest prices, to \$349.27, the highest, in 1905, a difference of 17.7 per cent. As determined from 2,567 families furnishing information in 1905, the cost of food represents 42.54 per cent of all family expenditures.

Russia's wheat surplus; conditions under which it is produced, I. M. RUBINOW (*U. S. Dept. Agr., Bur. Statis. Bul. 42, pp. 103, pls. 4, fig. 1*).—The author describes the conditions under which wheat is grown and harvested in Russia and points out the actual and possible exportations of wheat to European markets where it competes with wheat from other countries.

In the course of this study detailed facts are presented regarding the population and physical conditions of the country, system of land ownership, cereal production, the agricultural methods in vogue on private and peasant farms, and the wages of agricultural laborers, many of which factors bear upon the cost of wheat production. The two competing cereals in Russia are rye and wheat, and statistics are presented showing a steady gain in the cultivation of wheat. While the rye is consumed for bread by the peasants most of the wheat is marketed.

The primitive methods of agriculture, lack of modern implements and machinery, ignorance of the peasantry, and excess of spring sowings over

winter sowings are regarded as factors in lowering the yield of wheat. "Notwithstanding the exceptional fertility of the black soil which covers nearly the whole of the Russian wheat belt, the yield of wheat in Russia is found to be invariably smaller than in any country, with the possible exception of Argentina. . . . On the whole a spring yield of $8\frac{1}{2}$ bu. per acre and a winter yield of $11\frac{1}{2}$ bu. seem to be normal for the Russian Empire, with a grand average of a little over 9 bu."

From a commercial standpoint wheat is not regarded as low in cost of production under Russian conditions, the cost of raising winter wheat ranging from 46.5 to 66.6 cts. per bushel. "Excluding Poland, the average cost in European Russia proper varies between 46 and 54 cts. a bushel." The cost of spring wheat varies between 40 and 53 cts. per bushel.

In the opinion of the author the future development of the wheat-growing industry in Russia will depend upon the improvement of the economic and social conditions of the people by increasing the allotments of land to peasants, by better educational systems, and particularly by overcoming the greatest obstacle of all—the extreme poverty of the peasant.

[The sugar industry in Brazil] (*Internat. Sugar Com.*, [London], *Proc. Spring Sess.*, 1906, pp. 36).—This publication mainly consists of reports by several Belgian consuls residing at different places in Brazil and by the British vice-consul located at Rio de Janeiro which give statistics regarding the cost of production, quantity, and prices of grades of sugar, freight rates, export and import duties, etc. General information relating to methods of manufacture, shipping, and marketing sugar, as well as the part the Brazilian government has played in promoting the sugar industry, is included.

Season and crop report for the Province of Bengal for the year 1905-6 (*Dept. Agr. Bengal, Season and Crop Rpt.*, 1905-6, pp. 25).—Data are presented on the character of the seasons; area cultivated, cropped, and irrigated; production per acre and total production; prices, trade, and stock of food grains and other products; number of live stock and implements; and condition of the agricultural population.

MISCELLANEOUS.

Eighteenth Annual Report of Maryland Station, 1905 (*Maryland Sta. Rpt.* 1905, pp. XX+240).—The report proper contains the organization list, a report on the work and expenditures of the station during the year, and a financial statement for the fiscal year ended June 30, 1905. Reprints of Bulletins 94-103 of the station previously abstracted are appended.

Nineteenth Annual Report of Maryland Station, 1906 (*Maryland Sta. Rpt.* 1906, pp. XII+126).—This contains a report on the work and expenditures of the station by the director, a financial statement for the fiscal year ended June 30, 1906, and reprints of Bulletins Nos. 104-109 of the station previously noted.

Agriculture in other lands with special reference to dairying, J. A. KINSELLA (*Wellington: New Zcal. Dept. Agr.*, 1906, pp. 90, pls. 30).—Observations made by the author in Great Britain, Denmark, Canada, South Africa, and Argentina are reported.

Farm science (*Chicago: International Harvester Co.*, 1906, pp. 128, figs. 60).—This contains practical discussions of the following subjects: Alfalfa culture in America, by J. E. Wing; modern corn culture, by P. G. Holden; best methods in seeding, by W. F. Brown; small grain growing, by W. M. Hays; profitable hay making, by T. Shaw; up-to-date dairying, by C. D. Smith; increasing fertility, by C. G. Hopkins; and power on the farm, by F. R. Crane.

NOTES.

Florida University and Station.—R. W. Clothier, erroneously announced in a previous issue of the Record as the successor to C. M. Conner in the university and station, has been appointed professor of agriculture and horticulture in the university only. The position of agriculturist in the station has not yet been filled. R. Y. Winters, a graduate of Clemson College, has been appointed assistant in botany.

Georgia Station.—The station has recently erected a new laboratory building for the use of the new departments of bacteriology and plant breeding and plant pathology.

Idaho University.—A school of agriculture has been established, providing a 4-year course preparatory to the regular college work. A 4-year course in domestic economy is also announced.

Purdue University.—Farm mechanics has been added to the curriculum of the school of agriculture. It is to include class-room and laboratory practice in the subjects of farm machines, roads, buildings, and drains.

Iowa College and Station.—The department of agricultural extension, established as recently noted in charge of P. G. Holden, has been organized as follows: M. L. Mosher, in charge of farm crops; P. K. Bliss, in charge of animal husbandry; A. H. Snyder, in charge of soils; J. C. Guthrie, in charge of dairy; J. W. Jones, in charge of horticulture; Miss Mary F. Rausch, in charge of household economics; and G. E. Stayner, secretary.

In accordance with a law passed by the last legislature, facilities for instruction and research in cement and clay products have been provided, and 4-year and 2-year courses are being offered.

According to the *Iowa Agriculturist*, H. J. Quayle has resigned to continue entomological work at the University of California, and is succeeded by C. E. Bartholomew.

Maryland College.—The general agricultural course has been subdivided and separate courses are now offered in agronomy and animal industry, horticulture, and chemistry.

Montana College.—The general agricultural course has been expanded into separate courses in agronomy, animal husbandry, dairying, and horticulture. A 3-year elementary course in agriculture, continuing for 6 months of the year, has been offered in the newly created school of agriculture, to take the place of the 2-year winter course.

Nebraska University.—It is noted from *Science* that at a recent meeting of the regents of the university, the grade of "head professor" was established. Among the appointments made under this title were C. E. Bessey (botany), Lawrence Bruner (entomology), H. B. Ward (zoology), O. V. P. Stout (civil engineering), E. A. Burnett (animal husbandry), A. T. Peters (animal pathology), and Samuel Avery (chemistry). Most of the above are or have been connected with the station. It was further ordered that these head professors should constitute the "university senate."

New Mexico Station.—J. D. Tinsley, head of the department of soils, has been appointed superintendent of farmers' institutes and cooperative experiments, and will spend the greater portion of the year in traveling over the Territory organizing this work. George M. Lummis has been appointed assistant in the

department of soils and will have charge of the college classes and the experimental work. J. B. Thompson, recently appointed assistant in horticulture, has resigned to accept a position in the Philippine department of agriculture, and is succeeded by Lorenz Greene, a graduate of the Kansas College. It is planned to add an irrigation engineer to the station staff in the near future.

Cornell University and Station.—H. J. Webber, in charge of plant-breeding work in this department, has been appointed professor of plant biology, and will enter upon his new position in the spring. J. E. Coit, J. P. Stewart, and W. H. Griffiths have been added to the department of horticulture.

Oregon College.—A 4-year course in forestry, leading to the degree of B. S., has been added to the curriculum.

Pennsylvania College and Station.—Thomas F. Hunt, of Cornell, has been appointed dean of the college of agriculture and director of the station. He will continue in his present position until the close of the college year, giving a part of his time to planning for the future development of the work in Pennsylvania.

Vermont University and Station.—C. L. Beach, in charge of dairying at the Connecticut Storrs College and Station, has been placed in charge of the work in dairy husbandry in the Vermont University and Station. A. P. Bigelow, a former student at the dairy school, will be dairyman at the station, vice C. L. Stygles, resigned. It is expected rapidly to increase the work in dairying.

Armour Scholarships.—At a joint meeting of representatives of many of the agricultural colleges and the managers of the International Stock Show plans for the distribution of the Armour scholarships were decided upon. One scholarship will be given to each college leading at the exposition in judging horses, cattle, swine, sheep, and corn, one to the college making the best exhibit of feed stuffs, and one to the college making the highest average. The remaining 13 will be apportioned according to the winnings of the colleges at the show, except that no college may receive more than 40 per cent of the total number. The awarding of the scholarships to students will be done by the respective colleges.

Madras Agricultural College.—A new agricultural college and research institute for Madras is now in course of erection. In 1905 a grant to the presidency by the government of India of \$50,000 per annum, which was subsequently increased to \$100,000, added to the allotment made by the government of Madras removed all financial difficulty experienced by the Madras agricultural department. The result of this improved financial condition was the decision of the government to close the agricultural college at Saidapet and establish a new college and research institute, adequately equipped with laboratories and classrooms and with a suitable farm near Coimbatore.

The staff will consist of an expert agriculturalist as the principal of the college, a superintendent of the central farm, a government botanist, and an agricultural chemist. Ultimately an entomologist and mycologist may be added. The staff will combine teaching with research work. Problems connected with the agriculture of the presidency will be studied in the laboratory and the field, while the students will be given a general education in all branches of agricultural science.

Vacation Forestry Excursions.—The Royal Agricultural College of Cirencester has instituted for its forestry students a series of annual vacation excursions to the German forests. The initial excursion included visits to the Oberförsterei of Darmstadt, the oak and pine woods of Viernheim, the large coppice in the Odenwald now under conversion to high forests, and some of the Heidelberg woods. Shorter excursions to forest areas in England and Wales are frequent during the college year.

Association of Official Agricultural Chemists.—This association held its

twenty-third annual convention in Washington, D. C., November 7-9, 1906. The meeting was well attended. Prof. W. M. Hays, Assistant Secretary of Agriculture, Prof. C. E. Munroe, of the George Washington University, and Prof. Alexius de Sigmund, of Budapest, Hungary, upon invitation of the association, delivered brief addresses appropriate to the occasion.

The presidential address of C. G. Hopkins was entitled, "The Duty of Chemistry to Agriculture." This dealt mainly with the question of soil fertility, and included a review of investigations by the Bureau of Soils of this Department, work of the experiment stations in Illinois, Minnesota, and Ohio, and data obtained at Rothamsted.

In the following note concerning the proceedings no effort is made to incorporate the results of investigations as embodied in the recommendations of referees and committees as these are regularly published promptly in circular form by the Bureau of Chemistry. The detailed proceedings are also published by the same bureau. Reference will be made merely to the nature of the reports and papers which were for the most part submitted in abstract form.

The subject of food adulteration was, as usual, a prominent feature of the programme. Reports of 14 associate referees on this subject were presented. E. F. Ladd made a brief preliminary report on colors, which was supplemented by a paper by H. M. Loomis on the solubility and extraction of colors, and by a paper by A. G. Nicholls on the detection of certain vegetable colors in foods. C. H. Jones, associate referee on saccharine products, reported that the work on this subject during the year had been confined to maple products with particular reference to the malic acid value. Cooperative work by 13 analysts was reported. H. C. Lythgoe presented a report on fruit products. H. E. Barnard reported cooperative work by 10 chemists on the analysis of beer and recommended methods for adoption. C. A. Crampton reported on distilled liquors.

No report was presented on vinegar, but a paper entitled the Fuller's Earth Test for Caramel in Vinegar was submitted by W. L. Dubois. The method is considered unreliable and of value only as a preliminary test. E. M. Chace reported that the work on flavoring extracts had been confined to the proposed methods for the determination of citral in lemon oils and extracts. Results obtained by 4 chemists were included in the report. W. M. Allen, associate referee on baking powder and baking chemicals, reported work on the determination of carbon dioxide. L. M. Tolman, associate referee on fats and oils, reported that much had been accomplished during the year in the cooperative investigations on the cold test. H. C. Lythgoe submitted a brief report on dairy products for the associate referee, A. E. Leach. R. E. Doolittle reported on condiments other than spices. This consisted of an outline of methods which the associate referee had found of value in judging the products belonging to this class. C. D. Howard, associate referee on tea and coffee, reported that the work done by him on this subject during the year had been confined principally to a study of methods of determining caffeic acid. No cooperative work was undertaken. In this connection a review of the methods for chemical analysis of tea was submitted by R. E. Doolittle and F. O. Woodruff. This gave the results of determinations of water extract, tannin, and then by different methods.

A paper on the determination of moisture in tea by R. E. Doolittle and A. W. Ogden was also read. Drying in an oven was compared with drying in a current of hydrogen. W. L. Dubois, as associate referee on food preservatives, gave the results of his investigations on the determination of salicylic

acid in beer, wine, catsup, and other products. A. McGill, associate referee on cereal products, referred to definitions of grain, flour, etc., and reported a study of the literature on gluten, nongluten, nitrogen, valuation of flours, and gliadin. Investigations on the determination of water in foods were reported by F. C. Webber, associate referee on this subject.

The referee on the determination of nitrogen, J. B. Gibboney, reported considerable cooperative work on the determination of total and available nitrogen by different methods. In connection with this report J. P. Street read a paper on the detection of peat in commercial fertilizers. It was believed that a pentosan determination will indicate the presence of as small an amount of peat as 10 per cent. A report on the separation of nitrogenous bodies in cheese was submitted by the referee, R. Harcourt. The results of cooperative work on the extraction of water-soluble and salt-soluble products were included in the report. F. C. Cook presented a report of investigations on meat proteids.

Dairy products was reported upon by the referee, F. W. Woll, and papers on this subject by G. A. Olson and A. W. Bosworth were read. The latter dealt with the determination of acidity in cheese. J. K. Haywood reported upon feeding stuffs, and C. A. Browne, jr., upon methods of sugar analysis. Considerable work by the referees and collaborators upon sugar was reported. This has been mainly along lines previously studied by the association. The organic constituents of cane molasses were studied, and methods for the determination of nitrogen in molasses were compared. Data were presented showing variations in the polarization of raw cane sugars. The work on the unification of reducing sugar methods was reported by P. H. Walker. Tables for the estimation of dextrose, invert sugar, lactose, and maltose have been prepared and published. W. D. Horne submitted a method for the determination of sulphites in sirups.

A report on medicinal plants and drugs was submitted by the referee, L. F. Kebler. The referee on soils, J. H. Petit, reported cooperative work along the lines approved by the association at the last meeting. The referee on phosphoric acid, B. W. Kilgore, reported that investigations on the determination of available phosphoric acid in basic slag had been conducted, but that the results were not yet ready for publication. The associate referee, J. M. McCandless, reported the results of cooperative investigations on the determination of iron and alumina in phosphate rock and on the neutralization of the official solution of ammonium citrate.

The referee on inorganic plant constituents, W. W. Skinner, reported investigations on the amount of sulphur and phosphorus found in plant ash obtained by various methods. A. L. Knisely, referee on potash, reported cooperative work on the determination of potash in one sample of soil and in one sample of a mixed fertilizer containing considerable organic matter.

The report of the referee on tannin, H. C. Reed, was mainly an argument for discontinuing work by the association along this line. The association, however, voted to continue the work on this subject. A report on insecticides was submitted by the referee, G. E. Colby. This contained the results of preliminary tests of a simple method of determining the kerosene in kerosene emulsions by the centrifugal method.

The committee on food standards, through its chairman, W. Frear, submitted a report of progress. The committee was continued. H. W. Wiley, chairman of the committee on fertilizer legislation, submitted a report on conferences concerning a national fertilizer law. The committee was continued with instructions to secure, if possible, the collaboration of the great fertilizer in-

terests in the perfection of a measure to be submitted to Congress. In this connection a paper on the adulteration of commercial fertilizers was read by J. M. McCandless. Instances of adulteration of fertilizers in Georgia were cited.

A report on the testing of chemical reagents was submitted by the referee, L. F. Kebler. R. J. Davidson submitted a report of the committee on the unification of terms. The association deferred action on this matter for one year, the committee being continued. The committee on definition of plant food, H. W. Wiley, chairman, cited numerous authorities and recommended that plant foods be defined as those substances entering the plant from without and which are utilized in the metabolic activities of the plant. The definition was adopted by the association and the committee discontinued.

One of the special features of the meeting was the report of the committee on revision of methods. The methods of the association are at present embodied in two bulletins of the Bureau of Chemistry and in reports of the proceedings of the annual conventions. The task of revising these for publication in one bulletin has been left to the secretary of the association, aided by a committee on revision. It is expected that this revision of the methods will be published in circular form before the next meeting of the association, when final action can be taken.

The officers elected for the ensuing year are as follows: President, J. P. Street, New Brunswick, N. J.; vice-president, H. Snyder, St. Anthony Park, Minn.; secretary, H. W. Wiley, Washington, D. C.; additional members of executive committee, B. B. Ross, Auburn, Ala., and B. L. Hartwell, Kingston, R. I. The place of meeting for next year was left to the executive committee, preference being expressed for the Jamestown Exposition.

Association of Official Agricultural Chemists of Australasia.—At a meeting held at Sidney, New South Wales, August 20, 1906, and attended by representatives of Queensland, Victoria, New Zealand, and New South Wales, "The Association of Official Agricultural Chemists of Australasia," to consist of "the chief chemists for the departments of agriculture in the states and colonies of Australasia," was formally organized on lines very similar to those of the Association of Official Agricultural Chemists of this country. The objects of the association are stated in its constitution to be: "(1) To secure uniformity in the methods, results, and modes of statement of analyses of fertilizers, soils, feeding stuffs, agricultural products, and other materials connected with this industry. (2) To afford opportunity for the discussion of matters of interest to agricultural chemists."

The meeting took action upon forms of reports on soils for farmers, methods of analysis for soils, fertilizers, feeding stuffs, wheat and flour, dairy products, water, lime, insecticides, and cattle dips. Action on legislation regarding adulteration of fertilizers and other agricultural products and the fixing of standards was postponed, on account of the absence of representatives of some states and provinces, until the next meeting, which is called for March or April, 1907, in Sidney.

A committee was appointed to "investigate means for making short flying [soil] surveys and to test the rapid methods of analysis adopted by the American Bureau of Soils."

"The conference was unanimously of the opinion that all field experimental work should be carried out in conjunction with and under the supervision of the agricultural chemists in so far as relates to design and conduct of the experiments themselves and the interpretation and publication of the results." The extension of such work (*a*) by means of experiments conducted at state farms and agricultural colleges, (*b*) by experiments on the farms of private

individuals, and (c) by means of plats in school gardens, was recommended, and the scope and objects of field experiments were outlined. The supplementing of field experiments by pot experiments in the investigation of certain problems was also recommended.

The testing and certification of all calibrated glassware, especially that used in dairies and butter factories, and the allowable limits of error are to be reported upon at the next meeting. Referees were appointed to investigate and report upon the Kjeldahl method with and without the addition of mercury (C. J. Brünnich) and upon the determination of iron and alumina in phosphate rock (B. C. Aston).

The officers elected were F. B. Guthrie, president; C. J. Brünnich, vice-president; W. P. Wilkinson, secretary; B. C. Aston, additional member of executive committee.

Miscellaneous.—The first agricultural high school in Maryland was recently opened at Calvert. As previously announced, the school is under the management of the Cecil County school board, and H. O. Sampson, of this Department, is principal. The school has attracted considerable attention and is reported to be a success.

A new hall and science laboratories, affording accommodations for theoretical and practical work in agriculture, biology, physics, chemistry, and geography, have just been opened by the University College, Reading.

The consul-general of Panama reports that the Republic has contracted with Dr. D. H. Lupi, a well-known Venezuelan agriculturist, to establish a school of agriculture in Panama. Before opening the school Dr. Lupi will travel throughout the Republic and report his agricultural investigations to the government.

The *Industrialist* states that K. C. Davis, principal of the Dunn County School of Agriculture, of Menominee, Wis., has been offered a position as dean of St. Lawrence University, which, as previously announced, was granted an appropriation by the New York legislature for the establishment and maintenance of an agricultural course.

Prof. J. S. Newman, recently connected with Clemson College and the South Carolina Experiment Station, has been granted a pension by the Carnegie Foundation for the Advancement of Teaching.

T. H. Middleton, professor of agriculture in the University of Cambridge, has been appointed assistant secretary to the Board of Agriculture and Fisheries, in succession to Dr. W. Somerville, who has assumed charge of the instruction in agriculture and forestry at Oxford.

James T. Crawley, recently connected with the Hawaiian Sugar Planters' Experiment Station, has been appointed director of the Cuban Station, in succession to F. S. Earle.

NOTE.—The publications of the United States Department of Agriculture, except those of the Weather Bureau, may be purchased from the Superintendent of Documents, Washington, D. C. For the publications of the Weather Bureau requests and remittances should be directed to the Chief of the Bureau. The price of the Record is \$1 per volume, or 10 cents per number. The prices of other technical publications are given in the list above. The publications of the State experiment stations are distributed from the stations and not from the Department.

EXPERIMENT STATION RECORD.

VOL. XVIII.

JANUARY, 1907.

No. 5.

Interest in extension work in agriculture is developing rapidly. It is looked to as another means of making the work of the experiment stations more effective by bringing it home to the farmer in a way to appeal to him, and as spreading the influence and aid of the agricultural college. It proceeds upon the basis that the colleges can not give all the instruction in agriculture which is desirable within their walls, but that a vast body of adults outside may be reached and benefited by more direct contact.

Extension work differs from the college work proper in character, aim, and method. The college instruction in both regular and short courses is conducted at a central point at which the pupils must be assembled; and the courses are usually definite and fixed, and have a pedagogic form. Extension work seeks the farmer and rural population in their own surroundings, in much the same way that the farmers' institute does; and in a sense it may be regarded as a development and expansion of that form of aid, for in their present status the institutes are a conspicuous form of extension teaching. It must naturally be movable, elementary, and of short duration in any particular locality. It is informational in character rather than educational, for it can only present or demonstrate facts in a general way and in a quite didactic manner, and in the nature of the case can not go far into the reason and theory. While it is in this sense superficial, it is thought possible to give it something of the pedagogic form which is being worked out for other grades of agricultural instruction, by systematizing the various features and presenting them in logical order.

Extension teaching does not take the place of the short courses at the colleges, the elementary agricultural schools, or other agencies at present provided. It supplements the experiment station and the agricultural college, thus constituting a third branch of the system for agricultural instruction, which in its development may be regarded as separate and distinct in field and character, but closely correlated with the other two branches.

Although several kinds of extension work have been carried on for some time, the movement to organize it and give it more definite form as a department of the college is quite new. It is still in the formative stage, and the details of organization are yet to be worked out. The same is true of the scope to be given it, and its relations to certain phases of work which the agricultural colleges and the experiment stations are now doing, and to such agencies as the farmers' institutes.

But there is a widespread demand for more direct contact with the rural population, and a well-defined belief that in the form of extension work this will be the next significant development in the education of the American farmer. No one familiar with the conditions of agriculture in various parts of the country will question the great field of usefulness open to such a department. Soils are suffering and being depleted by lack of proper treatment to conserve their fertility, wasteful methods are pursued in handling irrigation waters and various by-products of the farm, weeds, insects, and plant diseases are allowed to devastate fields, poor seed and inefficient cultivation to greatly reduce quality and yield, and improper selection of cows and other stock to cut down the profit almost or quite to the point of loss. Economists and such men as James J. Hill are crying out against our improvident and reckless agriculture.

The experiment stations have in large measure worked out the remedies for these conditions, and pointed the way to more intelligent and remunerative practice; they have demonstrated these things to the farmers, and have spread the news broadcast through the popular bulletin, the agricultural press, the farmers' institute, and the railroad special. The good they have accomplished in this way is the strongest argument for a wider organization of extension work, for it demonstrates that the farmers can be reached and that a large proportion of them can be led to put the teachings of agricultural science into practice.

But the abilities of the stations in this line are limited by the other demands upon them. In entering upon such work they are stepping out of their field as investigators and delaying development along the lines with which they are especially charged. More and more it is becoming apparent that investigation and extension work in agriculture do not belong together, although mutually dependent and closely associated. The demands upon each are fast assuming such proportions that a separate force is becoming necessary to carry on the more important features of the work. There will be some overlapping for a time, as there will be with the regular educational work of the college, but the interests of all phases of the work are fast calling for greater differentiation.

The extension department seems the next logical step in the devel-

opment of our agricultural system. Those who have given the matter careful study believe that in view of the present feeling toward agricultural experimentation and education, the time is ripe for this step, and they point to indications that we are on the eve of a great extension movement in connection with the agricultural colleges.

The present status of extension work in the United States was brought out in the report of the committee on extension work at the Baton Rouge convention of agricultural colleges and experiment stations. This standing committee was appointed a year ago, at the time of the reorganization of the committees, and was an expression of the necessity and importance of this phase of work.

The committee defined extension teaching in agriculture to embrace "those forms of instruction in subjects having to do with improved methods of agricultural production, and with the general welfare of the rural population, that are offered to people not enrolled as resident pupils in educational institutions." It grouped the various forms of extension work under six headings, as follows: (a) Farmers' institutes; (b) itinerant lectures other than farmers' institutes, including traveling schools of various types, special railroad trains, etc.; (c) literature, including correspondence and reading courses, traveling libraries, etc.; (d) field demonstrations, educational exhibits at fairs, and the like; (e) educational features in charge of rural societies; and (f) formation of leagues or federations of rural societies, establishment of social centers, and similar undertakings. The classification is based primarily upon the kinds of work to be done, and secondarily upon types of institutions doing the work. The first four groups are intended to embrace all forms which belong primarily to universities, colleges, and other agencies whose work is distinctively educational.

In the committee's preliminary survey of extension work inquiries were sent to a wide range of institutions and organizations, agricultural and otherwise, to which a thousand replies were received. These show that there are already established over three hundred active centers of extension teaching in agriculture, and doubtless others for which no reports were received. "Nearly all the agricultural colleges and experiment stations in the land are doing extension teaching to a greater or less degree, and practically all of the granges and thousands of agricultural societies of various sorts do work that could be called extension teaching in agriculture."

Aside from these, it is interesting to note that the normal schools are not only giving courses in agriculture for teachers, but in several instances are sending out lecturers to teachers' and farmers' institutes, giving demonstrations, issuing pamphlets and school bulletins on agricultural subjects, and in other ways putting themselves in

touch with the farmers, teachers, and pupils in the rural communities. State and county superintendents of public instruction reported some form of extension teaching in one hundred and twenty-three cases, representing a great variety of forms; and seventeen State and local libraries reported that they maintain traveling libraries, lectures, lecture bureaus, etc., for agricultural subjects.

Commenting on the enormous amount of extension work which the experiment stations are doing, not only through their printed bulletins and the mass of correspondence of station officials, but also through demonstrations, lectures, and many other lines of effort, the committee asks "Why should the experiment station longer burden itself with extension teaching? Why should it not turn over all of the duties just enumerated to other hands and thus free itself in time, in money, and in energy, for concentration upon the gigantic problems of genuine research?" The obvious answer to this inquiry is the lack of other agencies with the organization and funds to meet the demands for this outside work, and the feeling of responsibility resting on station officers that their work must be adequately placed before the farmers, and that they must serve their interests in various ways. The stations probably feel the pressure for this assistance more keenly than any other agency, unless it be the farmers' institutes, for they are in such close touch with the farmers and their special needs. But there is no question that they would welcome departments equipped for this special object and working in close cooperation with them.

The committee emphasized the desirability of concentrating, coordinating, and systematizing the extension teaching in connection with the land-grant colleges, and of developing the more important aspects of it. It recommended that each college should organize as soon as practicable a department of extension teaching in agriculture, coordinate with other departments or divisions of the agricultural work, with a competent director in charge, and, if possible, with a corps of men at his disposal; and failing this, that it appoint a faculty committee on extension teaching in agriculture, to consider methods and all matters relating to this subject, and especially the feasibility of organizing definitely a department of college extension.

The report points out that "nearly all the institutions are feeling their way. The scattered nature and unorganized character of the work are obvious and significant. Only a few institutions have organized departments of extension teaching. The work thus far has grown out of the needs of the farmers and the desire of the younger institutions to win the regard of the farmers as well as to instruct them." And it adds that these efforts "have been seriously limited by the financial resources at hand and the small amount of time at the disposal of the employees of the institutions."

It is evident that extension teaching has secured a strong foothold in our system of agricultural education. It is felt that the time is not far distant when special appropriations will be made for this department of instruction, and that it is not too soon to begin the consideration of the proper organization of such work to meet the needs of various communities and conditions. Already several States are looking in that direction, and in Iowa a full-fledged extension department has been organized in connection with the agricultural college, manned by a corps of eight persons, which is now conducting itinerant schools with notable success. Eventually this new feature is destined to have a marked effect on the work of the agricultural college, the experiment station, and the farmers' institute, and will do much in enabling them to more effectively and fully realize their true missions.

CONVENTION OF ASSOCIATION OF AMERICAN AGRICULTURAL COLLEGES AND EXPERIMENT STATIONS, 1906.

E. W. ALLEN, Ph. D.,

Office of Experiment Stations.

The twentieth annual convention of this association was held at Baton Rouge, Louisiana, November 14-16, 1906. The headquarters of the association were at the Istrouma Hotel, where most of the sessions were held with the exception of the evening session, at which the presidential address was delivered, which took place in the assembly hall of Louisiana State University. The meeting was an unusually large one, and, as has been the case in recent years, it was made the occasion for the meeting of several societies and associations not affiliated with the association, although related to it in work. Among these were the Associations of State Universities, of Farmers' Institute Workers, and of Horticultural Inspectors, the Society for the Promotion of Agricultural Science, and the Economic Entomologists of the Cotton Belt.

The association enjoyed the hospitality of Louisiana State University and the experiment station, and under their auspices an excursion was made by boat to the Cinlaire sugar plantation and factory, about 8 miles down the Mississippi River, where opportunity was offered to follow the cane from the field through the various stages in the sugar factory, to the separation of the crude sugar. This excursion proved a pleasant social event, and a most interesting experience to a large proportion of the delegates, who were thus given a more definite impression of an important agricultural industry. Following the convention many of the delegates spent a day in New Orleans as the guests of Tulane University, and participated in a banquet given in their honor.

GENERAL SESSIONS.

The general sessions were presided over by President M. H. Buckingham, of Vermont, who delivered the annual presidential address on the evening of the first day. This was in the main a plea for placing greater emphasis upon the liberal and "humanistic" culture studies in the curriculum, as a means of preventing narrowness and

crudeness of thought and character. Such training, it was believed, should take the form of instruction in foreign languages, literature, history, economics, philosophy, and especially ethics and religion.

Even though the function of the land-grant colleges is to produce industrial experts, the speaker held that they should graduate liberally educated experts, men who know one subject thoroughly and many fundamentally. "The great problem of the higher education now before us is how to integrate specialism with the totality of which it is a part;" and each college was urged to see that its strongest emphasis is put "upon what in any and every educational institution is its main object and should be its highest ambition and satisfaction and glory—its human output."

The report of the executive committee, presented by Dr. H. C. White, reviewed the events of the year—the passage of the Adams Act, its interpretation, the limitation of the period for which the act makes appropriation, the Comptroller of the Treasury holding that it terminates with the fiscal year 1911, the second session of the graduate school, and the efforts of the committee in behalf of various measures before Congress. Initial steps were taken by the committee for the establishment of a department of rural education in the National Educational Association, but failure of the association to hold a meeting prevented action. The committee was in correspondence during the year with the president of the board of trustees of the Carnegie Foundation for the Advancement of Teaching, with reference to including the land-grant colleges among the beneficiary institutions of the foundation. It was invited to present the matter to the trustees at a meeting to be held November 21, 1906, and Dr. H. C. White was subsequently designated by the committee as its representative in that matter.

The association passed a resolution expressing its gratitude to the executive committee for its painstaking and efficient efforts in connection with the passage of the Adams Act.

The report of the treasurer showed receipts from dues of \$1,500, disbursements amounting to \$1,537.49, leaving—with the balance carried over from last year—a balance of \$958.38. The treasurer also accounted for subscriptions to the fund for the graduate school from 22 institutions for 1905 and 16 for 1906, amounting in all to \$950. Of this amount \$127.48 was paid for expenses of the committee on graduate study, and \$822.52 was turned over to the University of Illinois toward paying the expenses of the school.

The report of the bibliographer, Dr. A. C. True, consisted of a list of books written by agricultural college and experiment station officers. The list included 385 titles of books, the work of 195 men and women now or at one time connected with agricultural

colleges and experiment stations. Books on practically all phases of agriculture and allied sciences were represented in the list, showing the large and creditable contributions of the colleges and stations of this country to the literature of scientific agriculture in its more finished and permanent form.

The executive committee in its report referred feelingly to the death during the year of President G. W. Atherton, foremost among those who organized the association, its first president, and one of its wisest counselors; and of Hon. Henry Cullen Adams, of Wisconsin, "author and achiever of the latest National legislation in benefaction of agricultural research and agricultural progress." The committee had arranged for memorial addresses at the convention, and set apart an hour for their presentation.

The first of these addresses was by Dr. H. P. Armsby, A Memorial of George W. Atherton. The speaker reviewed the salient incidents in Dr. Atherton's varied career, noted his activity in connection with the formation and the work of the association, his efficient services in securing National legislation for the land-grant colleges, and his successful labors for his own institution. The speaker warmly eulogized Dr. Atherton's work and achievements for industrial education, his courageous leadership, indefatigable energy and high ideals, particularly as exemplified in the remarkable development of Pennsylvania State College during the twenty-four years of his presidency.

"Dr. Atherton had the courage and poise of the born leader of men. Never dismayed or disconcerted by opposition or attack, accepting defeat as the stepping stone to future success, with an open mind welcoming every suggestion from others, yet with supreme confidence in his own carefully considered conclusions, he bore his great responsibilities with a quietness and simplicity which were an inspiration to his associates. He was an optimist in the best sense, believing profoundly that right is stronger than wrong and that high and worthy ideals must ultimately triumph, and he showed his faith by his works."

Remarks were made by President James K. Patterson, expressing the esteem in which Dr. Atherton was held by his colleagues in the association, and a resolution of respect to his memory and appreciation of his services presented, which was adopted by the association by a rising vote.

The memorial upon Henry Cullen Adams, read by Prof. W. A. Henry, was an affectionate tribute to the life and services of Mr. Adams as an earnest and able champion of agricultural progress. The paper containing as it did many personal references to the character of the man, and following the progress of the Adams bill

through extracts from his letters to the speaker, was of the greatest interest to members of the convention, who were led to appreciate more keenly than ever Mr. Adams' strength of character, his noble, high-minded purposes, and his deep, intelligent interest in agricultural advancement. "In his going American agriculture lost the truest, wisest friend it ever had in the halls of Congress."

Remarks were made by Dr. White and Dr. True upon Mr. Adams's broadmindedness, his determined interest in promoting the work of the experiment stations, and his unselfish devotion to public service which caused him to die a poor man. There was a very widespread feeling that in the death of Mr. Adams the association and agriculture in general have sustained an unusual loss, and that his place can not be easily filled.

The committee on instruction in agriculture presented a short report through its chairman, Dr. A. C. True. A series of illustrative exercises, covering the general principles of the subject of agronomy, is being published by the Office of Experiment Stations, and will be followed by similar publications covering other branches of agriculture.

The committee has organized subcommittees on secondary courses, on courses in home economics, and on courses in rural engineering. The subcommittee on secondary courses has in preparation a syllabus of a course for use in the regular public high schools, and a series of lessons and practicums showing more fully the character and scope of this course, which it is expected will be published through the Office of Experiment Stations. The subcommittees on courses in rural engineering and on home economics have been engaged in studying the existing status of such courses in the land-grant colleges as a preliminary.

The report of this committee was followed by a lengthy discussion in which the interest of the association in this work was brought out, and its desire for the early publication of the results of the committee's studies, for use in connection with various grades of agricultural instruction. It was followed by the report of the standing committee on graduate study, by Dean L. H. Bailey.

Speaking of the purpose of the school he said: "This graduate work stands for a kind of teaching that lies beyond the college grade and that makes strongly for originality and personality. This enterprise expresses the conviction of the association that agricultural subjects are as capable as any others of advanced study, that they have equal and similar pedagogical value, and that there is need of the pursuit of them. . . . The unqualified success of the second session of the graduate school established the fact that graduate work is in demand. This school is now the only meeting ground for

teachers and investigators in agriculture. The comradeship of it is itself worth the while. . . . The experience with the two sessions of the graduate school indicates that no agricultural college or experiment station can afford not to participate in it if the institution expects to keep in living touch with the knowledge and opinions of the day."

An account was given of the second session of the school, held at the University of Illinois the past summer. (See E. S. R., 17, p. 1129.) The total enrollment was 131 persons, as against 75 persons in the first session. The total expense of holding the session was \$3,168.15. Toward this the colleges contributed \$950, less \$127.48 for traveling expenses of the graduate committee; and the university collected \$710 in fees. This leaves a net balance standing against the University of Illinois of \$1,635.63 as its contribution to the undertaking.

The committee recommended that the reports of the dean and the registrar of the school, together with other papers relating to it, be published in pamphlet form as a history of the movement. It also recommended that in locating the sessions of the school, the equipment of the institution for postgraduate work should be taken into consideration, that the next school should be located now, and the faculty chosen at once, and that the contributions of \$25 from each college toward the support of the school be continued. The committee presented invitations for the graduate school from Iowa State College and from Cornell University, and Dr. W. H. Jordan extended the invitation of the New York State Station in connection with that of Cornell University. The report of the committee was adopted, including the recommendations, and the place of holding the next session of the school was left to the committee.

The report of the committee on extension work was presented by President K. L. Butterfield. This report defined extension teaching in agriculture, and grouped the various forms of extension work under six heads. The main part of the report consisted of a summary of the present status of agricultural extension teaching in this country, on the basis of a circular letter which was widely sent out. The committee recommended that each college establish as soon as practicable a department of extension teaching in agriculture, coordinate with other divisions of the agricultural work and in charge of a competent director, and that pending such action a faculty committee be maintained to study the problem.

Much interest was shown in the report and in its early publication. The association placed itself on record as strongly in favor of adequate appropriations to the Office of Experiment Stations to enable it to enlarge its work upon agricultural education, the details of the

various forms of agricultural extension teaching, and to assist the different institutions to organize this form of work.

An interesting and important report was presented by Dean Davenport for the committee on station organization and policy. This report dealt largely with questions growing out of the Adams Act, and with the personnel of the stations. A summary of the main points covered was given in the previous issue (*E. S. R.*, 18, p. 301).

Mr. L. A. Kalbach, of the Bureau of Education, representing the new commissioner who had been invited to present a paper before the association but was unable to be present, read a paper on The Bureau of Education and the Land-Grant Colleges. The speaker reviewed the relations of the Bureau with the land-grant colleges, and presented statistics showing the increase in attendance at these institutions for the past ten years. In this period the number of agricultural students has increased from 2,712 to 7,418, and the students in mechanic arts from 5,317 to 12,969. The aid granted by the several States has increased from \$1,789,235 to \$5,768,786. The total income of the colleges for the last year was over \$11,500,000. The speaker held that the relation between the Bureau and the colleges was one of cooperation, and expressed himself as favoring its extension.

There was considerable discussion of the establishment of a National university, and of provision for graduate study in Washington. The Association of State Universities had considered the proposition of memorializing Congress to establish a National university at Washington, and appointed a committee to press this measure at the coming session of Congress. Through a committee consisting of Chancellor Andrews and President Fellows it asked the Association of Colleges and Stations to concur in the resolution of the Association of State Universities recommending the establishment of a National university. The discussion made it clear that the university was intended to be an institution for graduate work, taking advantage of the research agencies in the various Departments and Bureaus of the Government. As this matter of graduate study at Washington had received considerable attention from the association in the past, it was felt that it must be brought down to a practical basis before any satisfactory outcome could be expected. The association failed to concur in the resolution, and finally referred the matter to the executive committee to take such action as in its judgment seemed wise, and to make a full report to the association at its next meeting.

An important matter as affecting the policy of agricultural research in this country was embodied in a resolution presented by Dr. Arnsby. This resolution called for the appointment, to be made

by the incoming president of the association, of a commission consisting of five persons, two representing the research efforts of the association, one the U. S. Department of Agriculture, and two representing the scientific men not connected with official agricultural investigation, "the duty of which shall be to inquire into and report to this association the organization and policy which, in the opinion of the commission, should prevail in the expenditure of public money provided for scientific experimentation and research in the interests of agriculture, to the end that such funds shall be applied in the most economical, efficient, and worthy manner to the production of results of permanent value."

A very interesting discussion followed this resolution, during which there was brought out a consciousness of the lack of unity of purpose in the research and experimental efforts in this country, the feeling that agricultural science was not taking the definite form it should, and that the research work was not so organized and conducted as to command the respect and recognition of other branches of science which it should receive. There was a feeling that for the purposes of research the various agencies in this country, partly from lack of system, have not been as efficient as they might be made, and that much good might come from an impartial survey of the whole field by men competent to analyze the situation and to plan broadly. This resolution was adopted, but the commission has not yet been announced.

A resolution of President K. L. Butterfield, pointing out the desirability of the association meeting at least once in four years in connection with the National Educational Association, and providing a programme upon the discussion of methods of teaching agriculture and allied subjects, was turned over to the executive committee with instructions to take the matter under consideration.

The association put itself on record as favoring an attempt to secure increased Federal appropriation for education in agriculture and mechanic arts, and instructed its executive committee to cause a measure, drawn on the same general lines as the second Morrill Act, to be introduced into Congress. Such a measure has since been introduced into both branches of Congress.

A resolution presented by President Thach, reciting the brief time which the stations had to dispose of the first appropriation under the Adams Act, and requesting the executive committee to "secure such remedy as may seem practical," was adopted.

The officers elected for the ensuing year are as follows: President, L. H. Bailey, of New York; vice-presidents, T. D. Boyd of Louisiana, M. A. Scovell of Kentucky, B. C. Buffum of Wyoming, R. W. Stimson of Connecticut, and C. G. Hopkins of Illinois; secretary and

treasurer, J. L. Hills, of Vermont; bibliographer, A. C. True, of this Office; executive committee, H. C. White of Georgia, J. L. Snyder of Michigan, W. H. Jordan of New York, C. F. Curtiss of Iowa, and W. E. Stone of Indiana.

In the section on college work and administration, E. A. Bryan, of Washington, was chosen chairman, and H. C. Price, of Ohio, secretary. M. A. Seovell was elected chairman of the section on experiment station work, and C. E. Thorne, of Ohio, secretary. H. J. Waters, of Missouri, and H. T. French, of Idaho, together with the secretary of the section, were made the programme committee.

The members of the standing committees whose terms expired this year were all reappointed for the period of three years.

SECTION ON COLLEGE WORK AND ADMINISTRATION.

This section considered three main topics, each subdivided under a number of heads: (1) Administration of the land-grant colleges—organization and classification of the instructional force, control of student activities and student labor. (2) Relation of the land-grant college to the public school system, to the agricultural industries, and to the mechanical industries. (3) Curriculum of the land-grant college—study of home economics in the land-grant college, the short practical course, its place and importance, and agricultural extension.

There was no stenographic report of the proceedings of this section and few formal papers were read, the speakers assigned to the different topics speaking extemporaneously for the most part. It is not possible, therefore, to give an account of the meetings of the section.

SECTION ON EXPERIMENT STATION WORK.

This section occupied itself principally with questions relating to the Adams Act and agricultural research in general. The first session was devoted to a general discussion of The Kind and Character of Work under the Adams Act. Dr. A. C. True explained the provisions and limitations of the Act, the plans for the administration of the funds under it, and some of the difficulties experienced by the stations in inaugurating their new work.

Dr. H. P. Armsby urged that the stations should in a measure cut loose from the consideration of the legal aspects, and recognize not the necessity, but the opportunity under this Act. He pointed out that a great deal of our investigation heretofore has been directed to ascertaining certain facts, and he suggested that it might be well to make a distinction between experiments directed to ascertaining facts, and experiments directed to answering the questions how or why—that is, to correlating facts and establishing principles. He laid down the proposition that "original research is research directed to the establishment of the underlying principles of agriculture."

There was quite general recognition of the fact that a large proportion of our station work has been, from the necessities of the case, superficial, and that it has not gone sufficiently deep to establish fundamental principles. It was urged that there will necessarily result something of a differentiation among workers and among stations, and also a sharper line between teaching and investigation. In illustration of this, the work upon animal nutrition, carried on at the Pennsylvania Station with the respiration calorimeter, was cited as an instance of special fitness in the way of a leader and equipment which few stations could expect to attain. The results of such fundamental investigations are applicable to the country at large, and are of special interest and value to the experiment stations in connection with their feeding work. In recognition of this the section expressed its commendation of this work, and its hope that it would be continued and developed to the fullest extent deemed practicable by the board of control.

One of the difficulties recognized in the undertaking of research work was the lack of men suited to such work, for it was clearly shown that the main reliance must in the end be placed upon the men, and if they have not the proper conception of research and the spirit for it the work will not be of high order. Another difficulty frequently mentioned was the demand for practical results and the lack of interest by the general public in researches into fundamental principles. These things, however, will gradually right themselves as the work progresses, for it will attract men of proper training to it, and its practical value will become more broadly apparent.

The section passed a resolution recording its approval of the methods adopted by the Office of Experiment Stations for the administration of the Adams Act.

Three papers were presented before this section—one on Problems of Animal Nutrition, by Dr. H. P. Armsby; another on Methods of Experimentation in Feeding for Meat Production, by H. W. Mumford; and the third on Methods of Experimentation in Feeding for Milk Production, by J. L. Hills.

Dr. Armsby's paper was an able and scholarly review of the feeding work thus far carried on by the stations, its limitations, and the kind of investigation needed at the present stage of knowledge. Without underestimating the great value of much of the work done by the stations, the speaker believed it had "served only to a very subordinate degree to reveal principles. The latter we have seemed largely content to borrow from foreign investigators." He called attention to the limitations of digestion experiments and of the ordinary feeding experiments, pointing out the difference in efficiency of digestible matter of different feeding stuffs, as shown by the work of

Zuntz, Kellner, and himself. "We stand in urgent need," he said, "of actual determinations by modern methods of the nutritive value of feeding stuffs for different purposes, the results of which we may substitute for the assumptions on which we are now basing our teachings."

Among the subjects for investigation mentioned were studies upon the difference in the value of feeds for maintenance and for production, studies of the physiological value of individual chemical ingredients, the influence of aromatic and flavoring substances in feeding stuffs, variations in individual requirements of food for production, the protein requirement, and the influence of food upon the quality of the product. But in addition to these more scientific studies, the speaker emphasized the importance of the practical feeding experiment, remarking that "the more thorough and exhaustive our scientific studies of nutrition become, the greater will be our need for correlated practical experiments, scientifically planned, to answer definite questions regarding the application in practice of the principles worked out in the laboratory or the respiration apparatus."

This article was so suggestive of the needs of animal nutrition that it is hoped to publish it in full in a subsequent issue of this journal.

In the discussion of the paper Dr. Jordan called attention to the effect of certain mineral ingredients of the food upon digestion, and the reaction of certain food constituents upon the animal, as illustrations of a class of investigations which do not require expensive apparatus.

Professor Mumford's paper dealt with the essentials of practical experiments in feeding for meat production, precautions to be observed, and factors which influence the results and conclusions. The subject was treated under the head of the investigator and his point of view, the nature of the investigation, plan, execution, interpretation, and presentation.

Director Hills, in his paper on Methods of Experimentation in Feeding for Milk Production, divided his subject into the scheme, the animals, and their environment. He favored the alternation plan of testing rations, discussed the length of period, number of cows, period of lactation, and the extent of the experimental error, upon which the Vermont Station has been working for several years.

The report of the committee on unification of terms used in expressing analytical results, read by Dr. C. G. Hopkins, recommended the adoption as rapidly as possible of the element system of reporting results in case of fertilizers, soils, etc., and such changes in fertilizer laws as this would require. It suggested ten years as the period for making this gradual change from the present system. It

also recommended stating the composition of fertilizers in terms of "available" and "inert" nitrogen, phosphorus, and potassium, using these terms in the sense recognized by the Association of Official Agricultural Chemists; and, finally, that the source of the various fertilizing elements be required to be stated as a part of the guaranty.

These recommendations were conditioned on securing the concurrence of the American Chemical Society and the Association of Official Agricultural Chemists. The latter association considered a similar report at its recent meeting and decided to defer action one year. After considerable discussion, the report was adopted by the section, carrying with it the approval of the recommendations, and the committee was continued with instructions to seek to bring about international action.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY.

The rapid determination of phosphoric acid by weighing the ammonium phosphomolybdate, J. GRAFTIAU (*Bul. Assoc. Chim. Sucri. et Distill.*, 24 (1906), No. 3, pp. 315-320).—In the method described acid solutions of phosphates and phosphatic slag, corresponding to 0.2 gm. of material in case of ordinary superphosphates, mineral phosphates, and phosphatic slags, 0.1 gm. in case of rich phosphates and superphosphates, and 0.4 gm. in case of mixed fertilizers, are neutralized with ammonia to the point of precipitation, the precipitate carefully redissolved by nitric acid, and 10 cc. of Petermann's ammonium citrate added.

The procedure is then the same as with citric acid solutions, the treatment of which is as follows: Using the same amounts of material as in case of acid solution add 2 to 3 cc. of concentrated nitric acid, 10 to 15 cc. of saturated ammonium nitrate solution, 50 to 70 cc. of water, bring to the boiling point, remove the flame, and add 60 to 100 cc. of ammonium nitromolybdate. Allow to stand 15 to 30 minutes at about 70° C., remove supernatant liquor by means of a siphon, collect the precipitate on a small tared filter, and wash carefully with 1 per cent nitric acid. Dry for 2 hours at 105 to 110° C., and weigh.

Comparisons of this method with the citro-mechanical method showed somewhat higher results by the rapid method in case of superphosphates and phosphatic slag, but irregular variations in the case of mixed fertilizers.

Contribution to the titration of phosphoric acid, L. SCHUCIT (*Ztschr. Angew. Chem.*, 19 (1906), No. 41, 1708-1711; *abst. in Chem. Centbl.*, 1906, 11, No. 20, p. 1582).—This article discusses the influence of concentration, associated salts (particularly the addition of sodium chlorid), etc., on the results of titration of phosphoric acid and superphosphate solutions with sodium hydroxid and by the oxalate method.

A contribution to the determination of lime and magnesia, F. WESTHAUSER (*Ztschr. Angew. Chem.*, 19 (1906), No. 40, pp. 1682, 1683; *Chem. Ztg.*, 30 (1906), No. 80, p. 985).—This is a note on an article presented at the recent meeting of the German Association of Naturalists and Physicians, which discusses the application in analytical methods of the fact that when water solutions of magnesium chlorid are evaporated to dryness and heated a basic salt is formed which is very difficultly soluble in water, calcium chlorid under the same treatment remaining readily soluble in water.

Description of a calcimeter, N. PASSERINI (*Staz. Sper. Agr. Ital.*, 39 (1906), No. 1-2, pp. 28-32, fig. 1; *abst. in Chem. Centbl.*, 1906, 11, No. 12, p. 1019, fig. 1).—A simple apparatus for determining lime in soils by means of carbon dioxide evolved on treatment with acid is described.

Chemical soil analysis, E. A. MITSCHERLICH (*Fühling's Landw. Ztg.*, 55 (1906), No. 11, pp. 361-373).—A general discussion of this subject, being in a sense a preliminary notice of the author's treatise on soils, in which methods

of determining the available plant food of soil based on (1) solubility in water, and (2) solubility in water charged with carbon dioxide are fully described and advocated.

On the analysis of nitrate of soda, P. BECK (*Ztschr. Analyt. Chem.*, 45 (1906), No. 11, pp. 669-687).—A series of determinations on pure sodium nitrate and on samples of commercial nitrate is reported, which show that the indirect method in common commercial use is inaccurate and should be replaced by direct methods of analysis.

Scheibler's apparatus for the determination of carbonic acid in carbonates; an improved construction and use for accurate analysis, S. H. COLLINS (*Jour. Soc. Chem. Indus.*, 25 (1906), No. 11, pp. 518-522, figs. 3; *abs. in Bul. Soc. Chim. Paris*, 3. ser. (1906), No. 18-19, p. 1069).—Studies of the causes of error in the use of this apparatus are reported and a modification which is believed to secure greater accuracy is described in detail.

Determination of ash in an electrically heated furnace for elementary analysis, H. SEIBERT (*Chem. Ztg.*, 30 (1906), No. 79, pp. 965, 966).—Referring to a recent article by von Konek (*E. S. R.*, 18, p. 109), the author reports comparative determinations which show that with proper precautions this method of determining ash does not give higher results than the ordinary methods used. He attributes the higher results obtained by von Konek to occlusion of oxygen by the platinum vessel in which the incineration takes place in the furnace.

Report of committee on standard methods of water analysis to the laboratory section of the American Public Health Association (*Chicago, 1905*, pp. 141).—This is a reprint in pamphlet form of an article which has already been noted (*E. S. R.*, 17, p. 334).

The determination of total arsenic acid in London purple, E. G. MAHIN (*Jour. Amer. Chem. Soc.*, 28 (1906), No. 11, pp. 1598-1601).—The coloring matter is removed from the acid solution by means of chlorine gas. Several slight modifications are made in the methods of the Association of Official Agricultural Chemists for reducing the arsenic acid to arsenious acid.

A direct method for the analysis of milk, E. D'HUART (*Inst. Luxemb., Sect. Sci. Nat. [etc.], Arch. Trimest.*, 1906, Nos. 1-2, pp. 125-133, figs. 2).—Instead of sand or other absorbent material the author uses a roll of fine platinum wire gauze sufficient to absorb from 8 to 10 gm. of milk. The gauze containing the milk may be weighed in a covered crucible or in a weighing bottle. After drying to a constant weight and determining the total solids the fat is extracted in a Soxhlet apparatus and the ash subsequently determined on the same sample. Analyses made by this method in comparison with other methods are reported.

Experiments in relation to milk testing, H. HÖFT (*Milchw. Zentbl.*, 2 (1906), No. 8, pp. 355-360).—The changes in the total solids of buttermilk upon long keeping were found to be slight. During the first four days the decrease averaged about 0.16 per cent and during 6 or 7 days 0.33 per cent. After that the reduction was very slight.

The addition of ammonia to acid or curdled milk exerted no appreciable influence upon the determination of total solids. Ammonia was added to skim milk, buttermilk, and whole milk, and total solids were determined at intervals for about 3 months. The loss in total solids was small, the greatest amount during a period of 3 weeks being 0.17 per cent.

On the estimation of proteid in human milk, A. W. SIKES (*Jour. Physiol.*, 34 (1906), No. 6, pp. 481-489).—The results and conclusions of the author's investigations are stated as follows: (1) Precipitation of the proteid of human milk by means of hot alcohol is complete; (2) the hot alcohol extracts the non-proteid constituents completely; (3) the addition of a small quantity of citric acid prevents the precipitation of the salts; (4) the proteid is weighed directly,

not calculated from the amount of the nitrogen it contains; (5) by centrifuging the method is rendered more rapid than by filtering, and the washing of the precipitate is more thorough; and (6) drying of the precipitate is rapid.

A simple method for the quantitative determination of proteids in milk, T. R. BOGGS (*Bul. Johns Hopkins Hosp.*, 17 (1906), No. 187, pp. 3½, 3¾).—The proteids in milk diluted in the proportion of 1:10 are precipitated in an Esbach tube by means of a 10 per cent solution of phosphotungstic acid in about 3 per cent hydrochloric acid. The reading of the precipitate is made after 24 hours.

The rapid determination of water in butter, G. E. PATRICK (*Jour. Amer. Chem. Soc.*, 28 (1906), No. 11, pp. 1611-1616).—The author expels the water from 12 to 16 gm. of butter by boiling in a wide test tube over a naked flame. The water content as indicated by the loss in weight by this method is believed to be seldom if ever more than 0.3 per cent from the truth.

Direct determination of water in butter and other fats, C. ASCHMANN and J. P. AREND (*Chem. Ztg.*, 30 (1906), No. 78, p. 953, fig. 1).—This is based upon the distillation of the fat with xylol and the measuring of the water.

The refraction of nonvolatile fatty acids of butter, W. LUDWIG and H. HAUPT (*Ztschr. Untersuch. Nahr. u. Genussmitl.*, 12 (1906), No. 9, pp. 521-523).—This is considered of value in determining the adulteration of butter with 10 per cent or more of coconut oil. Butter from various sources showed refractometer numbers of the nonvolatile fatty acids varying from 29 to 30.2 and palmin from 16.1 to 16.5, while the addition of 5 per cent of palmin to butter reduced the refractometer number of the nonvolatile fatty acids to 28, the addition of 10 per cent to 26.9, the addition of 50 per cent to 22, and the addition of 90 per cent to 17.1.

On the detection of the adulteration of butter with coconut oil and oleomargarin, L. ROBIN (*Compt. Rend. Acad. Sci. [Paris]*, 143 (1906), No. 15, pp. 512-514).—The fatty acids in coconut oil are almost entirely soluble in 60 per cent alcohol at a temperature of 15° C., those of butter only partially soluble, and those of margarin only slightly soluble. In water the fatty acids in butter are much more soluble than those of coconut oil and margarin.

These characteristics are believed to be sufficient to enable the determination of mixtures of coconut oil and margarin with butter, and a method of procedure for this purpose is outlined.

On the detection of formaldehyde in milk, S. F. ACREE (*Jour. Biol. Chem.*, 2 (1906), No. 1-2, pp. 1½-1¾).—According to the author's investigations Hehner's test for formaldehyde in milk depends upon the presence of casein and lactalbumin, and the intensity of the color bears a relationship to the amount of these substances present. Of several aldehydes tested (acetaldehyde, paraldehyde, chloral hydrate, benzaldehyde, cuminol, and vanillin) vanillin alone gave the same reaction as formaldehyde. Other complex proteids as well as casein and lactalbumin gave the violet color with formaldehyde and sulphuric acid. The globulin from squash seed was found to give the most intense color and this substance was made use of in detecting formaldehyde in milk in concentrations less than 1 to 250,000. A method for this purpose is suggested.

Determination of salicylic acid in canned tomatoes, catsups, etc., W. L. DUBOIS (*Jour. Amer. Chem. Soc.*, 28 (1906), No. 11, pp. 1616-1619).—By the method suggested the color is removed before extraction with ether. The material is rendered alkaline with ammonia and then treated with milk of lime. In the filtrate from this mixture the salicylic acid is determined colorimetrically.

Boric acid: Its detection and determination in large or small amounts, W. H. LOW (*Jour. Amer. Chem. Soc.*, 28 (1906), No. 7, pp. 807-823, figs. 2).—

Modifications are suggested of the qualitative test with turmeric paper and of the quantitative test, which depends upon the ignition of the sample, distilling with methyl alcohol, and detection with indicators, the methods and apparatus being described in detail.

Attention is called to the wide distribution of boric acid normally in food products. "Boric acid occurs naturally in apples and probably in other fruits and vegetables. It is present in almost all common salt and some kinds contain relatively considerable amounts of it." Determinations of boric acid in a number of kinds of salt used in packing-house products showed the presence of 0.0435 to 0.76 grain per pound avoirdupois.

The fermentation of cane molasses, and its bearing on the estimation of the sugars present, G. HARKER (*Jour. Soc. Chem. Indus.*, 25 (1906), No. 17, pp. 831, 833-836).—The alcohol actually produced from the fermentation of cane molasses is generally much less than the possible yield as calculated from the determinations of saccharose and reducing sugars.

The author concludes from his investigations that this is due to the fact that the analytical figures overstate the amount of fermentable sugars actually present. A considerable portion of what analysis indicates as saccharose is not inverted by invertase and hence is not that substance. From the figures obtained in some of the experiments, the author found it possible to apply a correction to the ordinary analysis. Calling the possible yield of alcohol from a molasses 100, the corrected analysis indicated a yield of 85.8. It was found that the bodies which appear as saccharose in the analysis and which are inverted by acids but not by invertase are decomposed during the early stages of fermentation.

On various methods of determining total solids in wine, F. RONCALI (*Staz. Sper. Agr. Ital.*, 39 (1906), No. 4, pp. 289-322).—Direct and indirect methods of determining total solids in wine were compared on numerous samples from various sources.

A study of the methods for the determination of esters, aldehydes, and furfural in whisky, L. M. TOMAN and T. C. TRESKOT (*Jour. Amer. Chem. Soc.*, 28 (1906), No. 11, pp. 1619-1630).

A method for the determination of lead number in maple sirup and maple sugar, A. L. WINTON and J. L. KREIDER (*Jour. Amer. Chem. Soc.*, 28 (1906), No. 9, pp. 1204-1209).—The method proposed depends upon the use of a definite volume of standard lead subacetate solution and upon the determination of the lead remaining in this solution after it has been used as a precipitating reagent with a sample of maple sugar or sirup.

"The determination of ash and its characters and of lead number will usually suffice for the detection of the adulterants now in common use."

A new method of determining glycogen, E. PFLÜGER (*Arch. Physiol. [Pflüger]*, 114 (1906), No. 5-6, pp. 231-247).—The author discusses recent literature on glycogen determination and proposes some modification and amplification of his method of determining it.

Text-book of physiological chemistry, E. ABDERHALDEN (*Lehrbuch der physiologischen Chemie in Dreissig Vorlesungen.* Berlin and Vienna: Urban & Schwarzenberg, 1906, pp. VIII + 787, figs. 3).—In preparing this text-book the author states that he has selected those subjects of physiological chemistry which admit of reasonably complete treatment. The book includes 30 lectures, 4 of which are devoted to carbohydrates, 6 to proteids, 1 to nucleoproteids and other cleavage products, 2 to ash constituents, and 2 to metabolism.

This volume as a whole constitutes a summary of available information regarding the theories of nutrition and the views which are at present held regarding the chemical processes which take place in the body. The author

states that he has purposely omitted references to discussions of laboratory methods. Throughout the volume numerous references are made to the literature of the subjects treated, and indexes are provided.

Proceedings of the fifth annual meeting of the Association of German Food Chemists (*Ztschr. Untersuch. Nahr. u. Genussmitt.*, 12 (1906), No. 1-2, pp. 1-144).—This meeting was held at Nürnberg, May 25, 26, 1906.

Papers on the following subjects were presented and discussed: Food control and its difficulties, by J. König; spices, by E. Spaeth; fruit juices and jellies, by W. Fresenius; the examination and judging of carbonated lemonade, by A. Beythien; the use of saponin in carbonated beverages, by E. Schaer; judging the purity of water, by H. Grosse-Bohle; the glazing of coffee, by E. Schaer; cocoa and chocolate, by H. Beckurts; contribution to the knowledge of cocoa, by H. Matthes and F. Müller; the influence of cocoa on the organism, by R. O. Neumann; the solanin content of potatoes, by M. Wintgen; judging wine and wine legislation, by W. Fresenius; poisoning with phosphoreted hydrogen, by P. Lehnkering; and chemical investigations of Mosel wine, by W. I. Baragiola.

Report of the chemical section of the Wellcome research laboratories, Gordon College, Khartoum, W. BEAM (*Khartoum: Dept. Ed., Sudan Govt.*, 1906, pp. 205-244, figs. 15).—Included in this report are analyses of Nile River water; the milk supply of Khartoum; several commercial dried milks; Sudan grains, including wheat, corn, sorghum, millet, lentils, *Vigna sinensis*, and *Dolichos lablab*; salt; limestone; gums; and other products. Notes are given on the determination of viscosity of gum solutions, the use of asbestos as a funeral shroud, on a new form of hydrometer, on the determination of crude fiber, and on a simple form of blast lamp for use with benzine. The hydrometer consists of the ordinary form provided with a float made of a hollow ring of glass, supporting an upright short section of amber colored glass tubing, at the top of which rather than at the surface of the liquid the reading is taken.

Annual report on the progress in agricultural chemistry, 1905, T. DIETRICH ET AL. (*Jahresber. Agr. Chem., 3. ser.*, 8 (1905), pp. XXXVI + 561).—This contains the usual abstracts of important articles on agricultural chemistry appearing during the year with titles of articles of less importance.

Drug legislation in the United States, L. F. KEBLER and E. T. RAGAN (*U. S. Dept. Agr., Bur. Chem. Bul.* 98, pp. 217).—This is a compilation of all the National and State laws in force governing the sale of drugs.

METEOROLOGY—WATER.

The classification of climates, R. DE C. WARD (*Bul. Amer. Geogr. Soc.*, 38 (1906), Nos. 7, pp. 401-412, figs. 3; 8, pp. 465-477, pls. 2, figs. 7).—"It is the object of this article to give a brief summary of the general climatic types which result from the control of land and water, and of altitude over the more important elements of climate." The author describes particularly Supan's climatic provinces, the classifications of Köppen and Hult, and Ravenstein's hygrothermal types.

He concludes that the broad classification of climates as marine, continental, and mountain, with the subdivisions of desert, littoral, and monsoon is convenient for purposes of indicating the interaction of climatic elements under the control of land, water, and altitude, but for detailed study some scheme of classification in which similar climates in different parts of the world are grouped together and geographic distribution receives particular attention is needed.

Supan's classification is considered rational, simple, and satisfactory; Köppen's botanical classification is of value, but particularly for students of plant geography rather than of general climatology. It is stated that this "classification has the great merit of recognizing the existing differences of climate between east and west coasts, and between coasts and interiors. The coordination of districts of vegetation and of climate, which this scheme so strikingly emphasizes, is a noteworthy fact in climatology." Hult's classification is not considered to have any advantages over that of Supan. Ravenstein's hygrothermal types are said to rest upon unsatisfactory data.

Changes of climate, R. DEC. WARD (*Pop. Sci. Mo.*, 69 (1906), No. 5, pp. 458-470).—A general discussion of this subject in which the conclusion is reached that there is no sufficient warrant for believing in considerable permanent changes of climate over large areas. An eleven-year period of change has been made out, of more or less certainty for some of the meteorological elements, and a thirty-five-year period has been somewhat more positively determined, but as yet it has not been possible to make practical use of these periodic changes in forecasting.

"It was formerly believed that climate changes locally, but progressively and permanently. It is now believed that oscillations of climate are limited in time, but occur over wide areas. Finally, it is clear that man, whether by reforestation or deforestation, by flooding a desert or by draining a swamp, can produce no important or extended modifications of natural climate, which is governed by factors beyond human control."

Climate [of Alaska], C. ABBE, JR. (*U. S. Geol. Survey, Prof. Papers No. 45*, pp. 133-200, pl. 1, map 1).—This is a section of a monograph on the geography and geology of Alaska, summarizing the available records of temperature, precipitation, and casual phenomena which have been published since the appearance of Dall and Baker's work in 1879. The climatology of Alaska as a whole and of different districts of the Territory is discussed.

The work of the Weather Bureau and its relation to transportation, E. H. BOWIE (*Sci. Amer. Sup.*, 62 (1906), No. 1611, pp. 2518, 2519).—This is a paper read before the St. Louis Railway Club, which discusses briefly the nature and value of the predictions of the Weather Bureau in relation to transportation.

The public weather service of the German Empire, GROHMANN (*Fühling's Landw. Ztg.*, 55 (1906), No. 18, pp. 612-616).—This article discusses briefly the uniform weather service which was established for the whole German Empire June 15, 1906, and which has 14 forecasting centers, namely, Königsberg, Bromberg, Breslau, Berlin, Dresden, Magdeburg, Hmenau, Weilburg, Hamburg, Munich, Stuttgart, Karlsruhe, Strassburg, and Aix-la-Chapelle.

Special attention is given to the weather maps and the general conclusion is reached that a wider dissemination of meteorological information is necessary to the understanding and use of these maps.

Meteorological observations at Storrs, and general weather and crop review, W. A. STOCKING, JR. (*Connecticut Storrs Sta. Rpt. 1905*, pp. 215-222).—This is a record of observations on temperature and precipitation during each month of 1904 at Storrs; rainfall during the six months ended October 31, 1904, at 20 places in Connecticut; summary of rainfall for the six months ended October 31 for 20 places in Connecticut during the 15 years 1889-1903; monthly mean temperature and monthly precipitation for 16 years (1888-1903); and dates of last and first killing frosts for 16 years. The total precipitation for the year at Storrs was 40.19 in., 7.24 in. less than the average for the past 16 years. The principal deficiency in rainfall occurred in May, July, and November. The mean temperature for the year was 44.8°, 2.2° lower than the average for the

past 16 years. Deficiencies in precipitation and rainfall were quite general throughout the State. At Storrs the last killing frost in the spring occurred April 24 and the first in the fall, September 22, giving a growing season of 150 days free from frost.

Meteorological observations, J. E. OSTRANDER, R. C. LINDBLAD, and T. A. BARRY (*Massachusetts Sta. Met. Buls.* 213, 214, pp. 4 each).—Summaries of observations at Amherst, Mass., on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during September and October, 1906. The data are briefly discussed in a general note on the weather of each month.

[**Meteorological summary for 1904-5**], E. BURKE (*Montana Sta. Rpt.* 1905, pp. 279, 280).—The usual summary of observations on temperature, precipitation, cloudiness, etc., is given.

Report on meteorological observations during the year 1905 (*Overzicht der Meteorologische Waarnemingen, gedaan in den Cultuurtuin te Paramaribo, in het Jaar 1905.* [1906], pp. 16).—Summaries of tri-daily observations at Paramaribo on atmospheric pressure, temperature, humidity, direction of wind, cloudiness, and precipitation are given.

Antigua meteorological returns, 1905 (*West Indian Bul.* 7 (1906), No. 3, pp. 259-263).—Data are given for average rainfall in Antigua from 1874 to 1905, inclusive, monthly rainfall at a large number of places in the island during the year 1905, and monthly temperature, pressure, dew point, and wind movement at the government laboratory, St. Johns, during 1905.

Notes are also given on a cyclonic disturbance which occurred north of Antigua August 31 and September 1, 1906, with a discussion of the rainfall of St. Croix in relation to sugar crops. The general conclusions arrived at in the latter case are that a small amount of rain evenly distributed gives better results than larger rains falling unevenly. The rainfall of July, August, and September decides the crop of the next year whenever the canes are in a healthy condition at the end of June. Rain falling in January to March of the year the crop is taken off seems to have no influence.

British rainfall, 1905, H. R. MILL (*London: Edward Stanford, 1906*, pp. 88+271, pls. 7, figs. 11; *rev. in Nature* [London], 75 (1906), No. 1931, p. 5).—This, the forty-fifth annual report on British rainfall, is compiled from observations by 4,096 volunteer observers in different parts of the British Isles. The distribution of the rainfall both in space and time is discussed as well as the relation of total rainfall during the year to the normal.

Original articles of special interest are a review of Hellmann's report on precipitation in the North German river basins, and a study of the relation of evaporation from a water surface to other meteorological phenomena, namely, temperature of air and soil, duration of sunshine and rainfall, relative humidity, and amount of rain at Camden Square.

The report shows in general that 1905 was exceptionally dry, the rainfall deficiencies for the year being for England and Wales 16 per cent, for Scotland 5 per cent, for Ireland 12 per cent, and for the British Isles as a whole 12 per cent. The average rainfall during the year was 28.8 in. for England and Wales, 43.04 in. for Scotland, 35.8 in. for Ireland, and 33.92 in. for the British Isles.

The observations on evaporation as related to other meteorological phenomena were made at Camden Square by means of a standard iron tank 6 ft. square and 2 ft. deep, the rim of the tank rising 3 in. above the surface of the grass-covered ground and the surface of the water being maintained nearly at the ground level. Measurements were made by means of a hook-gage resting on the rim of the tank and read by means of a vernier to the hundredth of an inch. The

results show that "when the rate of evaporation was below the average for the year, it followed the mean temperature; when it was above the average for the year it followed the sunshine and the black-bulb temperature, and that the wind appeared to have had but little effect upon it." The rainfall during the year at Camden Square was 22.97 in., the evaporation 16.14 in.

The mean of the records of evaporation at 11 different stations shows that the amount of evaporation increased steadily to July and then fell uniformly until the end of the year.

The rains of the Nile Basin in 1905, H. G. LYONS (*Cairo: Al-Mokattam Printing Office, 1906, pp. 40, pls. 9*).—This report includes tables and maps of monthly rainfall and data and diagrams of Lake Victoria levels, of Nile floods, and of gage readings for Lake Albert, Bahr el Ghazal, White Nile, Blue Nile, Atbara, and Nile.

The physiography of the River Nile and its basin, H. G. LYONS (*Cairo: National Printing Dept., 1906, pp. VIII+411, pls. 48, map 1*).—This monograph deals in an exhaustive manner with the dimensions, geology, climate (particularly rainfall and winds), and water régime (floods, river flow, lake levels, etc.) of the different parts of the Nile Valley. A bibliography of 216 references is given.

Hail, LOISEL (*Abs. in Rev. Gén. Agron., n. ser., 1 (1906), No. 6-7, pp. 250-254*).—This is a review of an article discussing the nature and origin of hail and the damage caused by hailstorms.

It is stated as a result of a number of observations that ordinary hailstones weigh from 4 to 5 gm., although some have been observed which weigh 600 gm., and a few which exceed 1 kg. in weight. Hailstorms are said to be most frequent in the spring and summer, June and July being the months of maximum frequency. They are associated with storm conditions in which electric phenomena are most evident, and it is believed electrical activity plays an important part in the formation of hail. It is stated that hail is formed at high elevations, probably at the summits of the cumulo nimbus storm clouds, which are usually from 4,000 to 5,000 meters high. Hailstorms are usually of very short duration, not exceeding, in the author's observations, 5, 10, or at most, 15 minutes. Contrary to the general belief it is claimed that the distribution of hailstorms is not affected by topography. Data are given showing the enormous loss from hail in France.

On hail and weather shooting, R. BAUR (*Ztschr. Angew. Chem., 19 (1906), No. 40, p. 1678*).—This is a note on a discussion at the recent meeting of the German Association of Naturalists and Physicians on the relative efficiency of different kinds of ordnance for this purpose.

The mechanics of water softening, J. J. ROYLE (*Jour. Soc. Chem. Indus., 25 (1906), No. 10, pp. 452-456, figs. 4; abs. in Bul. Soc. Chim. Paris, 3. ser., 36 (1906), No. 18-19, p. 1068*).—Apparatus for use in the lime-soda process of water softening is described.

Underground waters of Tennessee and Kentucky west of Tennessee River and of an adjacent area in Illinois, L. C. GLENN (*U. S. Geol. Survey, Water-Supply and Irrig. Paper No. 164, pp. 173, pls. 7, figs. 13*).—This report is based upon the results of a part of the summer's field work and of subsequent trips over various portions of the area dealt with, as well as upon correspondence with owners of wells and springs and well drillers.

The report deals with "an area in western Tennessee and Kentucky and southern Illinois in which the surface formations are for the most part unconsolidated deposits that were laid down in an embayment of the great sea that once existed in the Mississippi Valley. In Tennessee this embayment area in-

cludes the portion of the State between Mississippi and Tennessee rivers with the exception of a narrow strip along the west bank of Tennessee River. In Kentucky it includes all of the State west of Tennessee River with the exception of a narrow strip that extends along the west bank almost to Paducah. In Illinois it includes a large part of Massac, Pulaski, and Alexander counties."

The main topics discussed in the report are source of underground water, artesian conditions, physical features of region, geology, underground-water resources, mineral waters of western Kentucky, and methods and cost of well drilling.

A bibliography of 50 references to the most important articles on the geology and hydrography of the region described is given.

The effect of copper upon water bacteria, K. F. KELLERMAN and T. D. BECKWITH (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 100, pt. 7, pp. 19*).—The results of a study of the resistance of several species of bacteria commonly occurring in Potomac River water to copper sulphate solutions of various strengths are reported, as well as of the effect of carbon dioxide on the viability of *Bacillus coli* and *B. typhi*, and of the relation of copper sulphate treatment of water to filtration.

In the first case the results indicate "clearly that no danger to most of the common saprophytic bacteria can be expected from using concentrations of copper sufficiently strong to destroy *B. coli*."

It was found that the presence of carbon dioxide materially increased the resistance of *B. coli* and *B. typhi* in tap water and in triple-distilled water alone and with the addition of calcium carbonate.

Experiments on the use of copper sulphate in connection with filtration showed "that in mechanical filtration with alum it is necessary to limit the use of copper sulphate to treatment some hours before coagulation. When solutions of aluminum sulphate and copper sulphate are mixed and alkali or hard water is added in quantities sufficient to cause precipitation the copper is coagulated at once, while the aluminum is deposited on the copper and incloses it, with the result that the copper-alum coagulum is no more toxic than is the pure alum coagulum. When copper and iron salts are precipitated together the reverse of this seems to take place and the precipitate retains its toxic properties. . . . The presence or absence of carbon dioxide is probably important in this connection."

On the use of *Bacillus prodigiosus* as an indicator in water examination, R. HILGERMANN (*Arch. Hyg., 59 (1906), No. 2, pp. 150-158*).—Investigations of the behavior of this color-producing organism under different conditions are reported which indicate that it is not reliable as a quantitative means of ascertaining the bacterial efficiency of filters.

Prevention of stream pollution by distillery refuse based on investigations at Lynchburg, Ohio, H. STABLER (*U. S. Geol. Survey, Water-Supply and Irrig. Paper No. 179, pp. 34, pl. 1, figs. 5*).—"This report gives an account of investigations carried on near Lynchburg, Ohio, to discover feasible means of preventing the pollution of streams by distillery refuse. Lynchburg is in Highland County, Ohio, a few hundred yards east of the East Branch of Little Miami River and about 60 miles northeast of Cincinnati. It has a population of a little less than 1,000. Above and below Lynchburg the East Branch of Little Miami River flows through an agricultural district, and as the town has no sewerage system the stream is not seriously polluted except by the distillery refuse. The investigation was therefore confined to the following subjects: (1) The processes at the distillery and the sources of pollution; (2) the effect

of the pollution on the stream; (3) the economical disposal of distillery wastes in such way that there will be no pollution of streams."

As a result of practical trials evaporation of the distillery refuse, using the residue for cattle feed and the distillate as water for mashing, is strongly recommended.

SOILS—FERTILIZERS.

Soil analyses, E. A. MANN (*Jour. Dept. Agr. West Aust., 14* (1906), No. 2, pp. 122, 123).—Thirty analyses of soils from different parts of Western Australia are reported, with brief comments on the results.

"The principal features of these analyses are: (1) The large number of 'acid' soils. (2) The frequent deficiency in lime. (3) The generally low percentage of total fertilizing constituents. This deficiency is often made up by mechanical conditions favorable for the free penetration of the root system. (4) The relatively large proportion of 'available' to 'total' phosphoric acid and potash in some instances. (5) The lack of humus."

On the composition of soils of French Guiana, A. HÉBERT (*Compt. Rend. Acad. Sci. [Paris], 143* (1906), No. 1, pp. 64-66).—The results of analyses of 63 samples are briefly summarized, showing that the soils are very variable in physical characteristics and that there is generally a sufficient supply of nitrogen and a great deficiency of phosphoric acid, potash, and lime.

The soils of the Muganj steppe and their transformation into alkali soils, S. SACHAROV (*Zhur. Opuitu. Agron. (Russ. Jour. Expt. Landw.), 6* (1905), No. 2, pp. 176-242, figs 4; *Izv. Moscov. Sel'sk. Khoz. Inst. (Ann. Inst. Agron. Moscou), 12* (1906), No. 2, pp. 226-236; *abs. in Centbl. Agr. Chem., 35* (1906), No. 8, p. 567).—The geological origin and chemical and physical properties of 3 typical soils of this region are described in detail, as well as the characteristic vegetation on each. A considerable proportion of the soils is more or less impregnated with alkali of the neutral white kind composed of chlorids and sulphates of the alkalis and alkaline earths. The distribution of this alkali in the soil under different conditions and the influence of irrigation in causing its spread are discussed, the author comparing his observations on this subject with those of similar character reported by Hilgard.

A contribution to the study of the sand in tropical soils, A. VAN BILJERT (*Chem. Weekbl., 3* (1906), pp. 413-420; *abs. in Chem. Centbl., 1906, II, No. 6, p. 555*).—Determinations of the amount of hygroscopic moisture absorbed from a saturated atmosphere, of nitrogen absorbed from a solution of ammonium sulphate, and amount of matter insoluble in hydrochloric acid and potassium hydroxid of sands and sandy soils from Java are reported.

The author concludes in general from the data obtained that a chemical study of soils is of more importance than mineralogical and mechanical examination.

Influence of cultivation of the soil on the conservation of moisture and the yield of crops, D. CHOUCIAK (*Bul. Agr. Algérie et Tunisie, 12* (1906), No. 12, pp. 237-247, fig. 1).—An account is given of experiments in the Crimean Peninsula which show that cultivated fallow contained at the end of summer 4 to 6 per cent more moisture than uncultivated.

How long does lime last in the soil? A. D. HALL (*Jour. Bd. Agr. [London], 13* (1906), No. 6, pp. 321-330).—Data largely derived from observations at Rothamsted are presented to show that the fertility of many English fields to-day "is due to the liming and chalking that was done by the farmers of the eighteenth and earlier centuries."

It is shown, however, that the fertility due to this cause is being steadily

exhausted by cultivation and by percolating rain water. "For example, the Rothamsted soil, which at the beginning of the nineteenth century must have contained something like a hundred tons of chalk per acre, has now less than fifty, and many other soils which started with a smaller initial stock are beginning to run dangerously short. All over the country there is evidence that much of the land, especially on the heavier soils, is in need of liming, and though it would not be wise to return to the old wasteful dressings of 6 to 10 tons to the acre, a much smaller quantity, half a ton or so per acre, could be profitably applied at least once in the course of each rotation."

The chemical and physical action of salt water on soils, D. J. HISSINK (*Chem. Weekbl.*, 3 (1906), pp. 395-403; *abs. in Chem. Centbl.*, 1906, 11, No. 4, p. 352; *Jour. Chem. Soc. [London]*, 90 (1906), No. 528, 11, pp. 701, 702).—Investigations are reported which show that the chemical action of small amounts of salt water, as in case of lands occasionally overflowed by sea water, is in general beneficial in increasing the solubility of most of the soil constituents. The physical effects, however, are not so favorable, the salt water tending to puddle and compact the soil.

The effect of fertilizers on the reaction of soils, F. P. VEITCH (*Science*, n. ser., 23 (1906), No. 592, pp. 710-712).—See E. S. R., 17, p. 431.

On the insoluble alkaline compounds formed in dead leaves, M. BERTHELOT (*Ann. Chim. et Phys.*, 8, ser., 8 (1906), May, pp. 36-41).—Investigations are reported which show that dead leaves contain considerable amounts of alkaline compounds insoluble in water, particularly salts of potash, which exhibit the phenomena of double decomposition and equilibrium with solution of salts of weak acids, such as acetic acid.

On the insoluble alkaline compounds formed in the organic matter of soils, M. BERTHELOT (*Ann. Chim. et Phys.*, 8, ser., 8 (1906), May, pp. 41-45).—The experiments here reported yielded results similar to those obtained in the case of dead leaves noted above.

On the insoluble alkaline compounds formed by artificial humus compounds of organic origin, M. BERTHELOT (*Ann. Chim. et Phys.*, 8, ser., 8 (1906), May, pp. 45-51).—By repeated treatment with hydrochloric acid a humus compound was obtained from soil which contained from 3 to 4 per cent of nitrogen. When this substance was treated with potash solutions a salt was obtained which on prolonged washing lost the major part of its potash but still retained from 3.7 to 6.2 per cent of insoluble potash.

Similar results were obtained with dead leaves and with compost.

Experiments with wood charcoal, M. BERTHELOT (*Ann. Chim. et Phys.*, 8, ser., 8 (1906), May, pp. 51-57).—See E. S. R., 17, p. 842.

Irrigating sediments and their effects upon crops, R. H. FORBES (*Arizona Sta. Bul.*, 53, pp. 55-98, figs. 10).—This bulletin reports the results of a study of the fertilizing and physical effects of sediments upon soils, in continuation of previous work along this line (E. S. R., 14, p. 423).

In this investigation a study has been made not only of the effect of ordinary stream sediments but of mine tailings from concentrating plants. The streams of the Southwest carry unusually large amounts of sediments, particularly in times of flood. Measurements are reported which show that the Gila River at Florence carries an annual average of 19.23 tons of silt per acre-foot, the Salt River at McDowell 1.2 tons, the Colorado at Yuma 9.62 tons. The amounts of fertilizing materials in these sediments are calculated to be, for the Gila River, 214.3 lbs. per year of potash, 36.9 lbs. of phosphoric acid, and 28.1 lbs. of nitrogen; for the Salt River, 18 lbs. of potash, 6.6 lbs. of phosphoric acid, and 5.5 lbs. of nitrogen; for the Colorado River, 113.1 lbs. of potash, 10 lbs. of phosphoric

acid, and 4.8 lbs of nitrogen. Of course there are wide variations in amount and composition of the sediments at different times.

A study of mine tailings which find their way into the Upper Gila River shows that they differ but little from the natural sediments as regards potash and phosphoric acid, but that they are lacking in nitrogen and organic matter, the constituents most needed in the desert soils.

The most pronounced effect of the free use of irrigation water containing large amounts of sediment is the formation of a silt blanket which interferes with the penetration of irrigation waters and in other ways impairs the physical condition of the soil. Experiments on the effects of these silt deposits on the growth of alfalfa during the summer of 1905 on 3 fields situated respectively under the Colorado River near Yuma, under the Salt River near Phoenix, and under the Gila River near Solomonville, are reported. In case of the field on the Gila River the irrigation water used contained a large amount of tailings from the concentration of copper ores. Observations were also made on a number of alfalfa fields along the Upper Gila River.

The results show in general a marked injurious effect from the accumulation of sediments in alfalfa fields, but like results from the use of water rich in sediments were not in general observed in the case of corn, barley, and wheat. In the case of such crops the ground is cultivated in a manner impossible with alfalfa, and the sediment blanket is broken up, turned under, and incorporated with the soil. In this way the blanketing effect is lessened or entirely done away with and the sediments are left free to exert such fertilizing influence as they may possess. It is therefore concluded that "in all cases cultivation, as deep, thorough, and frequent as practicable, is the prime means both of utilizing beneficial sediments and of mitigating the effects of harmful ones."

As compared with the natural sediments the mine tailings were of little or no fertilizing value and were fully as injurious from the standpoint of the physical properties of the soil. Certain injurious effects which have been popularly ascribed to mine tailings are shown to be due to other causes, such as plant diseases of various kinds, which have no relation to the water sediments. It is believed, however, that sunburning of crops, which is common throughout the Southwest, is due largely to the use of turbid irrigating waters.

Methods of lessening sediments in irrigating waters, especially the use of settling basins, are briefly discussed, and it is stated that "it is probable that, to an increasing extent, settling basins will be found a necessary adjunct to irrigating systems in the Southwest." In this connection mention is made of settling basins at present in use along the Colorado and Gila Rivers, and a brief account is given of the remains of prehistoric settling basins along the Salt River.

Assimilation of nitrogen by leguminous plants (*Nature* [London], 74 (1906), No. 1923, p. 475).—A brief reference is given to experiments at Midland Agricultural and Dairy College of England with Hiltner's pure cultures on tares, peas, alsike clover, alfalfa, and crimson clover grown in pots of boiled, sterilized quartz sand.

Inoculation proved beneficial in all cases. A method of inoculation which consists in mixing dried sterilized soil with crushed healthy nodules from the roots of plants of the same kind as those which it is desired to inoculate is described.

On the influence of bacteria on the metamorphosis of nitric acid in the soil, J. STOKLASA, J. JELINEK, and A. ERNEST (*Ztschr. Landw. Versuchsw. Österr.*, 9 (1906), No. 8, pp. 847-851; *abst. in Chem. Ztg.*, 30 (1906), No. 90, *Reprint*, No. 43, p. 386).—This is an account of a continuation of previous studies (E. S. R., 18, p. 215) and deals with the evolution of carbon dioxide and free nitrogen in Giltay

nutrient solutions, with and without addition of glucose and citric acid inoculated with soils of different kinds, especially those used in sugar-beet culture.

The conclusion is reached as in previous investigations that the organic matter occurring in such solutions as those experimented with does not furnish a readily available source of carbon for the respiration processes of denitrifying organisms and consequently nitric acid is not reduced to an appreciable extent in such soils. The authors are of the opinion that the decomposition products of the carbohydrates under the influence of micro-organisms are lactic acid, alcohol, and carbon dioxide, the decomposition of nitric acid in presence of alcohol taking place according to the following formula: $C_2H_6O + 2N_2O_3 = 2CO_2 + 4N + 3H_2O$.

Investigations on anaerobic nitrogen-collecting bacteria, E. HASELHOFF and G. BREDEMANN (*Landw. Jahrb.*, 35 (1906), No. 3, pp. 381-414, fig. 1; *abs. in Chem. Ztg.*, 30 (1906), No. 57, *Repert.*, No. 21, p. 223; *Jour. Chem. Soc.* [London], 90 (1906), No. 528, II, p. 698).—The authors report studies of (1) the occurrence and distribution of anaerobic bacteria similar to Winogradski's *Clostridium pasteurianum* in soils and on the leaves of various cultivated plants; (2) the capacity of these organisms to fix free nitrogen; and (3) the characteristics of the organisms as compared with *C. pasteurianum*.

The *Clostridium* forms of organisms were found to be widely distributed in soils and on the leaves of forest trees; in fact they were found in all of the samples examined. Pure cultures were isolated from cultivated soils. Both mixed and pure cultures of the organisms showed rates of assimilation of nitrogen similar to those observed by Winogradski with *C. pasteurianum*.

Calculated to 1 gm. of dextrose or mannite the amount of nitrogen fixed was according to Winogradski (*C. pasteurianum*) 2 to 3 mg., according to Beijerinck (*Azotobacter*, mixed culture) as high as 6.93 mg., Vogel (*Azotobacter* in mannite solution) 8.52 mg., Gerlach and Vogel (*Azotobacter*, pure culture) 8.9 mg., Haselhoff and Bredemann (mixed and pure cultures) 0.42 to 2.74 mg.

A morphological description is given of the isolated organisms and experiments which have been undertaken to determine the agricultural conditions best suited to the activity of the organisms are referred to. The methods used in obtaining the *Clostridium* cultures are fully described.

Formation of crystals in cultures of denitrifying bacteria, H. B. HUTCHINSON (*Centbl. Bakt.* [etc.], 2. Abt., 16 (1906), No. 10-13, pp. 326-328; *abs. in Jour. Chem. Soc.* [London], 90 (1906), No. 525, II, p. 477; *Chem. Centbl.*, 1906, II, No. 7, p. 621).—"Cultures of bacteria from garden soil in Giltay solutions produced skins consisting of acicular crystals of magnesium phosphate and became strongly alkaline. Denitrification was not vigorous. The alkalinity, which is presumably due to production of sodium carbonate from the citric acid, became equal to that of a tenth-normal solution in four weeks. The alkalinity and the amount of crystals seem to increase with increased surface and aeration."

The new nitrogenous fertilizers, J. SEBELIEN (*Tidsskr. Norske Landbr.*, 13 (1906), No. 2, pp. 49-81).—The article contains a summary of recent fertilizer trials with calcium cyanamid and lime niter in comparison with nitrate of soda and ammonium sulphate, and also reports on similar experiments conducted by the author and B. R. Larsen at Aas Agricultural College. The fertilizing effect of lime niter and nitrate of soda was found to be approximately the same, the small variations observed being attributable to differences in the character of the soils experimented with.

Pot experiments were made with oats on sandy soil, with oats and barley

on sandy soil mixed with clay, and with mustard and carrots on sandy soil. In several instances lime niter produced somewhat better results than nitrate of soda. This was due to the lime which it contained in addition to its nitrogen, as shown by the fact that pots fertilized with nitrate of soda and calcium carbonate gave higher results than nitrate alone, and as a rule results similar to those obtained from a corresponding amount of lime niter.

The author concludes that there is no reason to expect any difference in the fertilizing effect of a lime niter free from lead, and a nitrate of soda free from perchlorate and similar poisonous substances.—F. W. WOLL.

Nitrogenous fertilizers in 1905, K. RORDAM (*Tidsskr. Landökonom.*, 1906, Nos. 7, pp. 401-408; 8, pp. 433-452).—A discussion of the various nitrogenous fertilizers on the market, and especially of calcium cyanamid and lime niter, their method of manufacture, comparative fertilizer value, and the prospects of their future importance.—F. W. WOLL.

The oxidation of atmospheric nitrogen in the electric arc, F. M. PERKIN (*Nature [London]*, 74 (1906), No. 1922, pp. 444-446, figs. 4).—A brief account of various methods of electrical oxidation of the nitrogen of the air, but particularly of the Birkeland and Eyde process as developed at Notodden, Norway.

The utilization of water power in the electro-chemical manufacture of fertilizers, CÔTE (*Ann. Soc. Agr. Sci. et Indus. Lyon*, 1905, pp. 215-271, figs. 4).—A general discussion of this subject from the standpoint of rural economies, the synthetic preparation of nitric acid and cyanamids, liquefaction of air, and manufacture of copper salts.

Calcium cyanamid (Kalkstickstoff), H. FRANK (*Pure Products*, 2 (1906), No. 8, pp. 446-454).—This is a translation of a lecture before the Agricultural Club of Berlin, which describes briefly the methods of preparing this substance and its use as a fertilizer.

Results of tests of calcium cyanamid as a fertilizer (*Risultati di alcune prove di concimazione con calciocianamide. Rome*, 1906, pp. 44, figs. 27).—This is a compilation of experiments with this material on a number of different crops by various investigators.

Lime nitrogen, nitrogen lime, and nitrate of lime, GERLACH (*Deut. Landw. Presse*, 33 (1906), No. 44, p. 365).—The use and value of these products are briefly discussed.

Chilean nitrate deposits (*Jour. Franklin Inst.*, 162 (1906), No. 2, p. 159).—A brief note is given on the opinion commonly held by Chilean miners that the formation of nitrate deposits is due to atmospheric electricity. It is stated that "there is a remarkable amount of mist surcharged with electricity in the Pampas, where the saltpeter is mined, so much so that telephones are deranged. Apparently the ozonized air disengages nitrate of ammonia, which combines with rock salt to form saltpeter."

The Chilean nitrate of soda industry and the new cartel, P. KRISCHE (*Fühling's Landw. Ztg.*, 55 (1906), No. 16, pp. 563-568).—A general discussion of the condition of this industry with special reference to the nitrate supply of Germany.

Mountains of saltpeter, H. H. DUNN (*Tech. World Mag.*, 5 (1906), No. 4, pp. 397-401, figs. 4; *abs. in Amer. Fert.*, 25 (1906), No. 3, pp. 10-12).—The deposits of nitrate occurring in Death Valley, California, are described.

The utilization of peat bogs for the intensive production of nitrates, A. MÜNTZ and E. LAINÉ (*Compt. Rend. Acad. Sci. [Paris]*, 142 (1906), No. 23, pp. 1239-1244; *abs. in Jour. Chem. Soc. [London]*, 90 (1906), No. 525, II, p. 476).—Experiments are reported which show that "when a 0.75 per cent solution of ammonium sulphate is passed over a peat bed impregnated with nitrify-

ing organisms, it becomes charged with nitrates to the extent of 0.82 per cent. This can be increased to 4.17 per cent by adding a further quantity of ammonium sulphate to the solution and again subjecting it to the nitrifying action, the operation being repeated 5 times. The most suitable temperature for the reaction is 30°, and the fuel necessary for maintaining this temperature is afforded by the air-dried peat. Further, the nitrogen contained in the peat, which amounts to 2 to 3 per cent, can be obtained in the form of ammonia to the extent of 1.79 to 1.612 per cent by distilling the peat in superheated steam, the other products of the distillation (hydrocarbons, water gas, tar, etc.) forming the fuel required for the operation.

"Peat, therefore, is singularly well adapted for the intensive production of nitrates, since it forms an excellent medium for the growth of the organism, supplies the fuel necessary for the various operations, and finally supplies the ammonia required for the production of nitrates."

Nitrate of soda and nitrate and nitrite of lime in field experiments at Parc des Princes, 1906, L. GRANDEAU (*Jour. Agr. Pral., n. ser., 11 (1906), No. 25-26, pp. 753-755*).—Comparisons of nitrate of soda with nitrate and nitrite of lime obtained from the Notodden factories in Norway on corn and potatoes are reported. The results show that in general the Notodden products compare favorably with nitrate of soda, and that there is no injurious effect from the use of the nitrite as a fertilizer.

The action of nitrite on plants, A. STUTZER (*Jour. Landw., 5½ (1906), No. 2, pp. 125-138; abs. in Chem. Centbl., 1906, II, No. ¼, p. 353*).—Experiments are reported which show that nitrite injuriously affects germinating seeds, but that the injury varies with the kind of plant. Young beet plants are especially affected. Red clover at the end of the germinating period is resistant. With older plants the nitrite is not injurious and is in some cases less effective, in other cases more effective than nitrate as a source of nitrogen. The author believes that in the preparation of nitrogen compounds by means of electricity effort should be made to obtain a product as free from nitrite as possible.

Use of ammonium sulphate as a fertilizer, BACHMANN (*Fühdling's Landw. Ztg., 55 (1906), No. 13, pp. 451-459*).—Experiments are reported in continuation of those of previous years (*E. S. R., 16, pp. 245, 860*) which show that in case of rye one early spring (end of March) application of ammonium sulphate gave on the whole better results on both loam and sandy soils than fall or late spring applications. The same was true in case of summer cereals and beets.

The action of ammonium sulphate, especially in case of later applications, is controlled to a large extent by the rainfall during the season. Results were not conclusive as to the best depth of application for summer crops, but indicated that it should probably be deeper on loam soils than on sandy soils.

Production of sulphate of ammonia (*Jour. Bd. Agr. [London], 13 (1906), No. 6, pp. 359, 360*).—The production of this material in the United Kingdom during 1905 is given as 269,114 tons as against 245,990 tons in 1904. The average price in 1905 was about \$61 per ton.

Use of gypsum in the recovery of ammonia as a by-product in coke making, H. WARTH (*Chem. News, 93 (1906), No. 2½28, pp. 259, 260; abs. in Jour. Soc. Chem. Indus., 25 (1906), No. 1¼, p. 686*).—The use of calcium sulphate is recommended for the recovery of ammonia from gas liquor when large quantities of sulphuric acid are not available.

In experiments reported a sample of gas liquor containing 2.6 gm. of ammonia per 100 cc. was well shaken with gypsum, allowed to settle, and the clear liquid drawn off. From this clear solution it was found possible to recover 97 per cent of the ammonia present in the original gas liquor, namely,

17 per cent by boiling the solution and absorbing the ammonia evolved in sulphuric acid and 80 per cent in form of crystallized ammonium sulphate by concentrating the residual solution.

In order to dispense entirely with the use of sulphuric acid, the gas liquor was first treated with gypsum, the solution drawn off and treated with ferrous sulphate, the precipitated ferrous sulphide removed, and the clear solution evaporated to obtain crystallized ammonium sulphate. In this way it was found possible to recover 95.4 per cent of the total ammonia.

Further results of fertilizer experiments with agricultural phosphate, H. BACHMANN (*Jour. Landw.*, 54 (1906), No. 3, pp. 301-307; *abs. in Jour. Chem. Soc. [London]*, 90 (1906), No. 528, II, pp. 702, 703).—Field experiments on two sandy soils with rye and beets in continuation of those previously reported (E. S. R., 17, p. 17) are here recorded. The results are not entirely conclusive, but indicate that amorphous agricultural phosphate (fine-ground raw phosphate) is almost equal to Thomas slag in the first and second years. The action of apatite ceased after the first year.

Composition of deposits of phosphate of lime in the United States, P. JUMEAU (*Ann. Chim. Analyt.*, 11 (1906), Nos. 6, pp. 211-216; 7, pp. 256-261; *abs. in Chem. Centbl.*, 1906, II, No. 8, p. 705).—This is a continuation of an article previously noted (E. S. R., 18, p. 22) and deals with the plate rock, soft and pebble phosphates of Florida, and with Tennessee, South Carolina, and various minor phosphate deposits, including among the latter those of North Carolina, Pennsylvania, Arkansas, Alabama, Wyoming, Porto Rico, and Canada. Statistics of production, composition, etc., are given.

Granite rock potash (*Amer. Fert.*, 25 (1906), No. 2, pp. 16, 17).—This is a reprint of an article by C. G. Hopkins, of the Illinois Station, which maintains that "while there is reason to believe that heavy applications of finely ground granite rock carrying a considerable percentage of potassium can be used with profit on certain soils, and for certain crops under suitable conditions, it is unfortunate that such misleading and exaggerated statements should be made as . . . are published in several daily papers."

It is shown that 1 ton of potassium chlorid, at \$40 to \$50 per ton, contains as much potash as 10 tons of granite at \$3 per ton. "At \$3 a ton for granite and \$50 a ton for potassium chlorid, the amount of insoluble potassium which can be purchased in a ton of granite for \$3 is no greater than the amount of soluble potassium which can be purchased in 200 lbs. of potassium chlorid for \$5. The fact that the granite is insoluble, and very slowly available, while the potassium chlorid is soluble in water and readily available, more than counterbalances the difference in cost. Furthermore, the cost of transportation and application of one ton of granite as compared with 200 lbs. of potassium chlorid will also, in most cases, more than counterbalance the difference in cost."

Experiments by the Maine and Vermont stations are cited to show that the potash of granite dust and ground feldspar has a rather low fertilizing value.

Potassium mining crisis, T. J. ALBERT (*Mo. Consular and Trade Rpts.* [U. S.], 1906, No. 309, pp. 77-80).—The conditions which render it probable that the combination which now controls the output and price will break down are briefly discussed.

The use of lime and magnesia as fertilizer, O. LOEW (*Landw. Jahrb.*, 35 (1906), No. 4, pp. 527-540; *abs. in Chem. Ztg.*, 30 (1906), No. 70, *Repert.* No. 29, p. 287).—Experiments tending to show the necessity of maintaining in the soil a certain relative proportion of lime and magnesia and of keeping the latter in the less injurious forms (preferably carbonate) are reviewed and discussed. The importance of applying magnesia in some cases of excess of lime in the soil is pointed out.

Analyses and valuations of commercial fertilizers, J. P. STREET, W. P. ALLEN, and V. J. CARBERRY (*New Jersey Stat. Bul.* 196, pp. 35).—This bulletin reports analyses of 265 brands of complete fertilizers, 102 samples of unmixed fertilizing materials, 5 home mixtures, and 26 special fertilizers examined during the spring of 1906.

Fertilizers and feeding stuffs act, 1906 (*Mark Lane Express*, 95 (1906), No. 3911, pp. 274, 275).—The text of the revised British act is given and the principal points on which it differs from the old are briefly summarized.

AGRICULTURAL BOTANY.

Flora of Colorado, P. A. RYDBERG (*Colorado Sta. Bul.* 100, pp. XXII + 448).—This catalogue of species is based mainly upon the collections of the agricultural college at Fort Collins and the herbaria at the New York Botanic Garden, with additional records secured from other sources. The author has presented keys to the genera and species and under the specific name gives briefly the habitat and distribution of the plant.

The publication as presented stands as a brief index of the present knowledge of the flora of the State, and it is believed that it will be of use to all systematic botanists, to the schools of the State, and to all interested in the economic study of Colorado plants or in the flora of the plains and mountains of Colorado.

Rôle of seed coats in delayed germination, W. CROCKER (*Bot. Gaz.*, 42 (1906), No. 4, pp. 265-291, figs. 4).—A study has been made of some of the causes of delayed germination which is reported in seed of many plants, and contrary to the common view that the cause is generally to be found in the embryo the author finds that the structure of the seed coats is the determining factor.

Specific instances are given of delayed germination due to various peculiarities of seed coats. The author finds that seed coats which exclude water are much more liable to delays in germination than are seed coats which exclude oxygen. In nature, growth of delayed seeds comes about by the disintegration of the seed coat structures by longer or shorter exposure to germinative conditions.

In the case of seeds of the hawthorn there were found to be characters in the embryo which delayed germination, and in these instances the germination finally comes about through long exposure to germinative conditions but not in dry storage. The phenomena in delayed germination in the case of the cocklebur, various species of *Plantago*, and other plants are described.

The influence of sunlight and diffused light on the development of sugar beets, S. STRAKOSCH (*Separate from Österr. Ungar. Ztschr. Zuckerindus. u. Landw.*, 1906, No. 1, pp. 11, figs. 2).—The sugar beet, it is claimed, can form all the starch necessary to its growth in very diffused light. Nevertheless direct sunlight stimulates the formation of substances in the plant such as starch. A lack of direct sunlight increases the nonsugars in the beet juice as well as reduces the total sugar content. The latter, however, is not influenced in the same proportion as is the total size of the beet root.

Under similar conditions there is a greater amount of intracellular respiration in normal leaves than in those grown in greatly diffused light, although the latter show a stronger epidermal transpiration. In comparing sun and shade produced leaves the stomata of those grown in full light were found to be larger, and relatively more stomata were found on the upper and fewer on the lower sides of the leaves.

Translocation of the results of assimilation was continued longer in the case of shade-produced leaves. With an increase in light intensity there was found a

diminution of monosaccharids as compared with disaccharids. Dextrose is associated with the monosaccharids of the beet leaves. There are indications that cane sugar is not an intermediate product of beet leaves, but is a reserve capable of translocation to other parts of the plant. This the author expects to investigate more fully.

Injurious action of acetates and formates on plants, K. Aso (*Bul. Col. Agr., Tokyo Imp. Univ.*, 7 (1906), No. 1, pp. 13-24).—The author states that free acetic and formic acids even in considerable dilution are injurious to plants, although it was not to be expected that the sodium and calcium salts of these acids in moderate concentration would prove injurious to phanerogams. The effect of various acetates and formates was found to differ very materially from that of the oxalates, and marked differences were observed in the behavior of acetates and formates toward flowering plants and algae.

Experiments were carried on with various algae, seedlings of sorghum, onions, peas, barley, young branches of oak, and other plants, to show that the acetates and formates of alkaline metals and calcium act injuriously on flowering plants in solutions of 0.5 per cent or over, while under the same conditions they are not injurious to the higher algae. Neutral potassium acetate of the same concentration is poisonous to both phanerogams and higher algae.

The poisonous action of acetates and formates is held to be caused by the hydrolytic dissociation of these salts into acids and bases in the living cells, whereby the base is absorbed by the proteids and the acid being set free injures the protoplasm.

Stimulating influence of sodium fluorid on garden plants, K. Aso (*Bul. Col. Agr., Tokyo Imp. Univ.*, 7 (1906), No. 1, pp. 83, 84).—Pot experiments with seeds of a number of plants were carried on, which showed the stimulating effect of small quantities of sodium fluorid. The flowers appeared first in the pots which contained 0.02 gm. sodium fluorid. But little difference was noticed, however, in the size of the flowers in the treated and untreated pots.

The stimulating action of calcium fluorid on phanerogams, K. Aso (*Bul. Col. Agr., Tokyo Imp. Univ.*, 7 (1906), No. 1, pp. 85-90, pl. 1).—In other experiments the author has found that sodium fluorid acts as a strong poison on seeds and seedlings, although it exerts a stimulating effect on their development when highly diluted.

The fact that in soil cultures sodium fluorid passes readily into calcium fluorid, which is but slightly soluble, renders it probable that the stimulating compound in soil cultures is not sodium fluorid, but calcium fluorid. In order to determine this, experiments were made with peas and barley, which showed that calcium fluorid is formed in the soil when sodium fluorid is applied, and that as it is slightly soluble in water it can act as a stimulant of plant growth.

The degree of stimulating action of manganese and iron salts on barley, T. KATAYAMA (*Bul. Col. Agr., Tokyo Imp. Univ.*, 7 (1906), No. 1, pp. 91-93, *dgm.* 1).—Investigations with oats, upland rice, barley, and wheat have shown that the stimulating effect of manganese salts is less on cereals than on leguminous plants. Experiments were conducted to determine the amount of manganese salt necessary to produce as favorable results on the common cereals as have been obtained with this salt when applied to peas.

When fractional doses of high dilution were applied as top dressing, the results showed that 0.01 per cent of manganese and iron sulphates produced a moderate increase in the harvest of barley, but that a further increase led to a general decrease in yield.

The micro-organisms of natto, S. SAWAMURA (*Bul. Col. Agr., Tokyo Imp. Univ.*, 7 (1906), No. 1, pp. 107-110).—Natto, which is a kind of vegetable cheese

prepared by the fermentation of boiled soy beans, contains large amounts of mucilage, and the viscosity of the mixture is especially esteemed.

A study was made by the author to determine the bacteria present, and although many species were found to grow on soy beans, the genuine natto could be produced only by the presence of 2 species, which are designated as Bacillus No. 1 and Bacillus No. 2. It is probable that for the formation of good natto cheese both species must be present.

In order to test for enzymes produced on soy beans by the bacteria, precipitates were made and tested, in which way it was found that the enzym was of a tryptic nature. Bacillus No. 2 also produced a diastatic enzym, and from these facts it is inferred that natto may have some beneficial influence on digestion.

The drug known as pinkroot, W. W. STOCKBERGER (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 100, pt. 5, pp. 8, pls. 2, figs. 2*).—The drug known as pinkroot (*Spigelia marilandica*) came into use in America about 1723, and because of its valuable properties soon came to occupy an important place in materia medica. Conflicting reports on its physiological effects appeared from time to time, and its use has greatly decreased.

The cause of the apparent loss of high efficiency has been a subject for study for some years, and it is demonstrated that a substitute has to a considerable degree replaced the true article. This explains in a large measure its unfavorable commercial and medical status.

Results are outlined in the bulletin of a detailed study of the pinkroot and its more important adulterants, which may serve to aid collectors and drug experts in distinguishing the plant from its sophistications.

International catalogue of scientific literature. M—Botany (*Internat. Cat. Sci. Lit., 4 (1906), pp. VIII+951*).—This is the fourth annual issue of the catalogue of scientific papers compiled and published by the International Council of the Royal Society of England, and includes the literature of 1904 with some titles omitted from previous issues. About 4,600 titles are enumerated, the plan of grouping being about the same as that previously noted (*E. S. R., 14, p. 637; 17, p. 752*).

FIELD CROPS.

Report of work at McNeill Branch Experiment Station, E. B. FERRIS (*Mississippi Sta. Rpt. 1905, pp. 31-35*).—The work of the station for the year is briefly noted.

The results of fertilizer experiments showed that on the land parked with cattle during the winter of 1902-3 there was a yield of 1,300 lbs. more of seed cotton per acre than on three check plats. As a fertilizer for cowpeas acid phosphate alone gave practically as good yield as a complete fertilizer, and drilling $\frac{1}{2}$ bu. of seed produced as much pea hay as the use of 1 bu. of seed per acre. Good stands of alfalfa, crimson clover, and hairy vetch are reported. The hairy vetch was sown in the fall of 1902 and is reported as being in a most promising condition. Inoculating the vetch field produced a more vigorous growth and a good stand.

Subsoiling at the station has not shown any very marked results. This year 35.7 bu. of corn and 900 lbs. of seed cotton were obtained on land prepared 5 in. deep, and 37.1 bu. of corn and 1,025 lbs. of seed cotton per acre on land broken 18 in. deep during the spring of 1903. Rotation tests now in progress for 3 years with cotton, corn, oats, and cowpeas resulted during the last year on the rotation plat in a yield of 904 lbs. of seed cotton per acre as compared with 724 lbs. on a plat similarly fertilized but growing cotton continuously for the same length of time.

The work with small fruits, vegetables, Bermuda grass, cassava, sugar-cane, and live stock is briefly outlined.

Five years' results on the sewage irrigation fields of Arad, J. GYÁRFÁS (*Ztschr. Landw. Versuchs. Osterr.*, 9 (1906), No. 9, pp. 859-890).—A history is given of the sewage irrigation field and its management is described.

Vegetable culture gave in general unsatisfactory results. Kale for forage, poppy, corn grown for grain, and potatoes were also unprofitable. The sunflower was observed to transpire greater quantities of water than any other crop grown on the field. It made a very luxuriant growth, but was unprofitable on account of the difficulties in the way of its use. Broom corn produced brush from 60 to 100 cm. long and of the required degree of fineness. The yield of hemp under sewage irrigation was lower than the average yield for the entire country, but the fiber secured was of proper quality. Barnyard millet made an extremely heavy growth, while sugar beets were not successful. Fodder beets were the only hoed crop which gave good returns. Ridge culture for the fodder beet produced better yields than level culture, and beets grown from the seed without transplanting were more successful than transplanted beets.

Errors in field tests due to lack of soil uniformity, G. HOLTSMARK and B. R. LARSEN (*Landw. Vers. Stat.*, 65 (1906), No. 1-2, pp. 1-22, *djms.* 4).—This article, previously noted in E. S. R., 17, p. 963, appears here in German.

The Svalöf method for breeding agricultural plants and its relation to the theory of selection, H. DE VRIES (*Separate from Arch. Rassen u. Gesell. Biol.*, 3 (1906), No. 3, pp. 345-358).—A detailed description is given of the method followed at Svalöf in improving agricultural plants. The matter presented is compiled with a view to discussing from a scientific standpoint the value of the principle of selection in plant improvement.

The chemical composition of Washington forage crops, R. W. THATCHER (*Washington Sta. Bul.* 72, pp. 27, *dgm.* 1).—The experiments in progress have for their object the determining of the chemical composition of the hay crops as now cured in the eastern sections of the State, the variations and composition of hay from the same plant when grown under different conditions and in different sections, the analyses of several of the leading forage crops of the State in different stages of maturity, and the effect of different conditions and methods of curing upon the chemical composition of the hay. These investigations will require several years of study, and this bulletin is a report of only the first year's work.

The samples analyzed are briefly described and the composition of grass hay, grain hay, hay from leguminous crops, fodders, silage, and root crops, as determined by analyses, is given in tables. The digestible nutrients in the feeding stuffs analyzed are also shown.

The analyses show that the common grass hays, grain hays, and alfalfa hay contain about the same amounts of total digestible nutrients, but in widely different proportions, the grass hays being richest in carbohydrates and alfalfa richest in protein, while the grain hays contain these substances in a fairly well-balanced proportion for a maintenance ration. The analysis of timothy hay shows a surplus of carbohydrates and that of alfalfa of protein. It is stated that neither timothy nor alfalfa can be fed alone without waste. Alfalfa hay from irrigated sections appeared to be richer in protein than that grown without irrigation. It was also found that the total nutrients of alfalfa hay were about the same regardless of the stage of growth at which the crop was cut, but the proportion of protein was much greater when the crop was cut early than when cut late. From these results it is concluded that the ripener crop gets the more nearly it approaches to a balanced ration and the safer and

more economical is its use alone; but attention is called to the fact that beyond full bloom the proportion of crude fiber increases rapidly, with a corresponding decrease in total digestible nutrients. Alfalfa hay from the first, second, and third crop had apparently about the same composition if cut at the same stage of growth.

Some reasons for failure with alfalfa, T. L. LYON (*Cornell Countryman*, *4* (1906), No. 1, pp. 3-6, figs. 3).—Experiments were conducted to determine the causes of failure in alfalfa culture, and the practical suggestions derived from the results were that at least a moderately fertile soil is needed for this crop, that the use of phosphate as a fertilizer is valuable in this connection, and that inoculation is futile unless the soil is in a condition to favor the growth of the bacteria.

Adulteration of alfalfa seed, B. T. GALLOWAY (*U. S. Dept. Agr., Office Sec. Circ. 20*, pp. 2).—This circular reports on the examination of 352 samples of alfalfa seed obtained in the open market. Of these 160 contained dodder seed, 9 were adulterated with seed of yellow trefoil, and 9 with bur clover. The quantity of yellow trefoil found in the adulterated samples ranged from 3.75 per cent to 47.05 per cent, and that of bur clover from 1.12 to 20.28 per cent. The quantity of total adulterants found varied from 7.65 per cent to 53.28 per cent.

Tables for the determination of the protein content of barley, E. GLIMM (*Bromberg and Leipsic: E. Hecht'sche, 1907*, pp. 272, figs. 4).—Tables are given for the ready calculation of the protein content of the dry matter of barley after the analytical results have been obtained. These tables are applicable in all cases where the water content ranges from 10 to 17.90 per cent.

Brief directions for the determination of nitrogen are also given.

Culture tests with brewing barley, J. BEHRENS (*Ber. Landw. Vers. Anst. Augustenb., 1905*, pp. 60-67, 90-109).—Cooperative culture tests showed that common local varieties of barley failed to equal in quality and producing capacity the introduced varieties with which they were compared. This is believed to be due rather to improper seed selection than to a defect in the varieties. Chevalier barley was so unsatisfactory in both quality and yielding power that the variety is not recommended for general cultivation. The best results in quality and quantity for 3 years were secured with Goldthorpe, Hanna barley standing next.

Continuous corn culture, G. E. ADAMS and H. J. WHEELER (*Rhode Island Sta. Bul. 113*, pp. 99-114).—In the spring of 1894 the station decided to devote an acre of land to the continuous culture of corn.

The soil was partly a silt loam and partly a light sandy loam. The first 2 years only chemical fertilizers were used, the maintenance of soil humus being placed upon the corn stubble remaining upon the field. The following 2 years half of the area was sown with crimson clover at the time of the last cultivation of corn and half to rye, in order to compare the merits of a leguminous and nonleguminous crop as a means of maintaining soil humus. Beginning with 1898, after the experiment had been in progress 4 years, the first quarter of the acre plat was sown to crimson clover and the third quarter to winter rye at the time of the last cultivation of the corn, while the second and fourth quarter acre received no cover crop. In 1899 the land was limed to insure the success of clover. The history of the land is given and the fertilizer treatment and the results secured in each year are recorded.

A summary of the results during the 12 years the experiment has been conducted shows that the gain from using clover as a cover crop, after deducting the cost of the seed, was \$50.24, or an average of \$4.19 per acre annually, as compared with \$4.28, or an average of \$0.36 an acre annually from using rye.

Cotton culture in its relation to climate near the limits of the cotton belt, W. R. ECKARDT (*Inaug. Diss., Univ. Jena, 1906, pp. 115*).—The relation of the different climatic factors to the culture of cotton in the northern and southern hemispheres is discussed.

Special attention is given to cotton culture in the United States and the climatic conditions of this country are compared with those of Europe. In his discussion on cotton growing in the southern hemisphere the author points out the favorable climatic conditions in the German-African colonies for the culture of this crop.

A new type of red clover, C. J. BRAND (*U. S. Dept. Agr., Bur. Plant Indus., Bul. 95, pp. 45, pls. 3, figs. 2*).—This bulletin describes the performance and characteristics of a strain of red clover obtained from Orel, in the Black Earth region of Russia. Cooperative experiments have been carried on with this strain and with other red clover secured from various sources in this country and Europe, in Minnesota, North Dakota, South Dakota, Nebraska, Indiana, Ohio, and the Province of Ontario, Canada, and the results are here discussed.

The average purity of seed used in the experiments was 98.13 per cent. The seed showing the highest percentage of purity was secured from Oregon, which was 99.68 per cent pure, while the seed grown in New York contained the highest percentage of impurities, 7.46 per cent, or 92.54 per cent of pure seed. The average germination of all samples was 87.07 per cent, the range being from 58.2 per cent for seed from Courland, Russia, to 99.12 per cent for seed from eastern Ohio. A detailed description of the experiments carried on in each State is given.

A description of the new Russian type is given and its advantageous characters discussed. The designation *Trifolium pratense foliosum* is proposed. It is stated that this variety is distinguished by the dustlessness of its hay, due to the almost complete absence of hairiness; by its heavy yield for the first crop; by its leafiness and the persistency of the basal leaves, on which character the proposed varietal name is based; by the succulence of its stems; by the greater palatability as compared with hay from domestic seed; and by a later period of maturity, the harvest of this new type coming from 10 days to 2 weeks later than that of our ordinary red clover.

Reports received during 1906 confirm the observations made during the previous year. Reports during the present year on the growth of this variety, also referred to as Russian clover No. 16, on a Nebraska farm show that the plant has a tendency to become perennial. Of the different kinds of seed sown in 1904 the Russian clover No. 16 was the only strain that had a full stand from the first seeding.

Seed of red clover and its impurities, E. BROWN and F. H. HILLMAN (*U. S. Dept. Agr., Farmers' Bul. 260, pp. 24, figs. 39*).—This bulletin describes red clover seed and also gives descriptions of the more common impurities in the American and European grown article.

The extremes of good and bad seed are shown by the analyses of two samples, one of which, imported at 5½ cts. per pound, contained about 18¼ per cent of seed that would grow, though most of this was so inferior that it would not produce vigorous plants, while the other sample contained more than 95 per cent of seed that would grow and was practically free from weed seed. It is pointed out that in order to sow the same amount of good seed it would require 5¼ lbs. of the poor sample to 1 lb. of the other, and that every time 150 weed seeds were sown with the good sample, 733,567 weed seeds would be sown with the poor one.

It is stated that the average seed grown in this country contains about 300,000 seeds to the pound, seed produced in England about 222,000, that produced in Chili about 190,000, and that very poor seed often contains as many as 490,000 seeds to the pound.

A short treatise on the culture and handling of flax, B. STEGLICH (*Dresden: C. Heinrich, 2. ed., pp. 15*).—Brief notes on flax culture with reference to climate, soil, rotation, cultivation, fertilization, seed, and harvesting are given, together with concise directions for retting, drying, and marketing the crop.

The influence of external conditions on hemp and hemp fiber, J. BEHRENS (*Ber. Landw. Vers. Anst. Augustenb., 1905, pp. 41-43*).—The results of the experiments here described indicate that the free access of light fails to influence the development of fiber in the hemp plant.

A comparison of Improved Ligowo and Provence Gray oats, F. RICHTER (*Prog. Agr. et Vit. (Ed. Fest), 27 (1906), No. 45, pp. 567-570*).—In culture tests of these varieties the Provence Gray yielded 2,450 kg. per hectare and the Ligowo 3,270 kg. The hectoliter weight of the Ligowo was 43.5 kg. and that of the Provence Gray 43 kg.

It is concluded from the results secured that Ligowo Improved might be recommended for general culture either as a winter oats in southern localities or as a spring variety in the more northern regions.

Orchard grass, R. A. OAKLEY (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 100, pt. 6, pp. 16, pl. 1*).—This bulletin describes the methods followed in growing orchard grass for hay, pasture, and seed in different sections of the country.

It is stated that orchard grass yields on an average from 10 to 12 bu. of seed per acre, which sells for \$1.25 a bushel. When sown for seed it is advised to sow 1 bu. of seed per acre, and when grown for hay or pasture to use more than this quantity. Red clover sown with orchard grass at the rate of 1 bu. to 5 or 7 acres is considered a profitable mixture. Orchard grass sown together with tall meadow oat grass and meadow fescue for hay and pasture also gives good results. The seed is harvested about June 15 to June 25. The average life of an orchard grass meadow is given as from 5 to 7 years.

Potato culture experiments, J. BEHRENS (*Ber. Landw. Vers. Anst. Augustenb., 1905, pp. 57-60*).—The results secured showed that there existed no definite relation between the weight of the seed tubers and the yield. The seed tubers weighing 100 gm. each gave a higher average yield than those weighing less, but the exceptions were very numerous. The starch content of the seed tubers and that of the product secured seemed to bear no relation to each other. The starch production of individual plants was also apparently independent of the starch content of the seed tubers.

Sugar beets in Kansas (*Quart. Rpt. Kans. Bd. Agr., 25 (1906), No. 99, pp. 32, figs. 6*).—A series of articles giving the history and the present status of the beet-sugar industry in Kansas, with a record of its progress since the passage of the State bounty law in 1901. General directions on the culture of the sugar beet are included, and growing sugar beets in the Arkansas valley in Kansas is described.

Report on fertilizer tests with sugar cane, C. LEMARIÉ (*Bul. Écon. Indo-Chine, n. ser., 9 (1906), No. 53, pp. 629-635*).—Fertilizer experiments were conducted on naturally poor soils, especially deficient in humus.

The results showed that minerals alone were ineffective and that where insufficient quantities of barnyard manure were used the returns were also unprofitable. A heavy dressing of barnyard manure gave a somewhat smaller yield, but was nevertheless more profitable than an application of barnyard manure together with commercial fertilizer. The author concludes that the first need of the soil is a supply of humus.

Sunflower culture and its profits in Russia, V. WALTA (*Fühling's Landw. Ztg., 55 (1906), No. 20, pp. 701-708, fig. 1*).—The history of sunflower culture in Russia is given, together with a description of the methods followed. The quan-

cities of plant food taken from the soil by the crop are shown and the cost of sunflower production, together with the yields of seed and oil, are discussed.

Fertilizer experiments with tobacco, J. BEHRENS (*Ber. Landw. Vers. Aust. Augustenb., 1905, pp. 34-41*).—A comparison was made of martellin and other potash salts as fertilizers for tobacco. No increase in the yield of leaf which might have been attributed to the use of the fertilizers was secured. The different forms of potash also were almost without influence upon the quality in this test with the exception of the sulphate, which seemed to have reduced the quality slightly. High topping of plants seemed to favor the quality of the leaf.

In a second fertilizer experiment the influence of different fertilizer treatment was studied. Tobacco receiving no potash in the fertilizer showed the lowest potash content, but did not rank lowest in burning quality. The leaf with a high potash content ranked lower in burning quality than the produce which contained less potash.

These results are interpreted as meaning that the potash content is not alone, nor even predominant, in controlling the burning quality. The tobacco grown on the check plot which received no fertilizer treatment stood lowest in ash, but not in potash. The highest ash content was secured on a plot receiving potash, phosphoric acid, and nitrogen, followed by the plots receiving potash and nitrogen, and potash, phosphoric acid, nitrogen, and lime. The burning quality of the leaf did not seem to increase with the content of potassium carbonate.

Species of tobacco, their phylogeny, quality, and uses, O. COMES (*Naples: 1905, pp. 231, figs. 68; abs. in Bot. Centbl., 102 (1906), No. 36, pp. 268-270*).—The great variability in the different species of tobacco due to various causes is discussed, their history, geography, and statistics are given, and the importance of new phylogeny of every species and strain, in connection with the improvement of the crop, is pointed out. It is stated that individuals originating from the same plant are early in maturing when grown from the grains which ripen earliest on the mother plant, while the individuals from the later maturing seed are likely to be late in maturing.

The form *Nicotiana tabacum harauensis* introduced into a strain by breeding gives aroma to the product, while the form *Brasiliensis* increases leaf production.

Characters determining the quality of wheat, A. CERHÁTI (*Ztschr. Landw. Versuchsw. Österr., 9 (1906), No. 10, pp. 899-972*).—The results of experiments with different varieties of wheat are reported and data with reference to the weight per hectoliter, weight per thousand kernels, mealiness or softness, and protein and gluten content in their relation to quality are tabulated. It is concluded that the quality of wheat can not be determined by means of the different characters which were studied, and that the only definite way of judging wheats is by their milling products.

It is stated that the weight per hectoliter is a valuable factor only when the wheats compared are of the same variety and were grown in the same locality. It is known that the same wheat varieties grown under the same environment yield more flour when their weight per hectoliter is high, but when the wheats are not of the same variety or have been grown in different regions no reliance can be placed upon this character in judging the flour content.

The weight per thousand kernels, which is referred to as the absolute weight, was found to vary considerably. A normally developed wheat has an absolute weight of 25 to 55 gm. Foreign varieties grown in these experiments, which produced flour of an inferior quality, were higher in absolute weight than the Hungarian sorts. The domestic varieties as a rule weighed less than 40 gm., while the foreign wheats in nearly all cases weighed over 40 gm. per hundred

kernels. It is pointed out that this result does not necessarily indicate that wheat is better in quality on account of its low absolute weight.

The absolute weight and mealiness were correlated to some extent, wheats with a high absolute weight also ranking high in mealiness, and those low in absolute weight standing low in mealiness. Although this was generally the case, in many instances wheats grown in the same region were found to be exceptions to this rule. The absolute weight and the protein content of the material under investigation were inversely proportional to each other, but attention is called to the fact that this can not be a definite rule, because the protein content of varieties of the same absolute weight may vary considerably in different seasons. The correlation between the absolute weight and the gluten content was less evident than between absolute weight and protein.

In quality the mealy or soft wheats were inferior to the hard glassy varieties. The increase in mealiness of the grain was generally accompanied by a decrease in protein and gluten, but in a few instances this was not the case.

Protein content and quality are correlated in that wheats high in protein are usually superior in quality. The average results of the different analyses reported indicate that with a few exceptions the gluten content increased with the protein content. It was observed that the quality of the gluten and not its quantity determined the quality of the wheat.

HORTICULTURE.

Horticulture department, R. W. FISHER (*Montana Sta. Rpt. 1905, pp. 281-284*).—This gives a brief outline of the work of the year, with some details in regard to thinning experiments with apples.

In one case with Duchess and Wealthy trees ranging from 8 to 15 years old about $\frac{3}{4}$ of the crop, or an average of 918 apples, was taken from each tree. It required 15 minutes to thin the fruit from one Duchess tree and 22 minutes from each Wealthy tree, the trees in the latter case being larger and with a heavier crop of smaller fruit. At these rates it is figured that it would cost \$7 to thin an acre of Duchess trees and \$9.60 an acre of Wealthies. In some other experiments it required 9 minutes to thin fruit on McIntosh trees planted 18 ft. apart each way. For thinning Alexander trees 14 minutes was required. In all cases marked benefit in the increased size of the apples as the result of the thinning was noted.

Report of the horticulturist, F. GARCIA (*New Mexico Sta. Rpt. 1905, pp. 27-31*).—A general outline of the work of the year, with some details of the cost of producing chiles. The cost per acre of preparing the land, sowing the seed, irrigating, hoeing, cultivating, etc. for green chiles was \$15.82, seed \$1, picking \$12.78, hauling to cannery \$4.50, making a total cost of \$37.10 per acre. The yield was 7,536 lbs., which sold at the cannery for $1\frac{1}{2}$ cts. a pound, leaving a net profit for this crop of \$75.94. For red chiles the cost of production was \$43.04 per acre and the net profit \$116.26.

The Casaba melon, C. C. ROYCE (*Pacific Rural Press, 72 (1906), No. 20, p. 308*).—Letters from this Department are quoted, showing that seed of the Casaba melon was sent to parties in California as early as 1869.

Dwarf fruit trees, F. A. WARCH (*New York: Orange Judd Co., 1906, pp. 125, figs. 34*).—A popular account for amateur fruit growers of the propagation, pruning, and the general management of dwarf fruit trees in the United States and Canada is given.

It is believed that dwarf fruits, while of but little commercial importance in this country, may find a place in the gardens and small grounds of people living

in cities and towns. Some of the advantages of the dwarf trees are the early bearing habit, small size, high quality of the fruit, suitability for suburban places, as orchard fillers and as illustrative material for school gardens, and for covering walls and fences. Among the disadvantages are the greater expense of the trees, greater care required in their management, and their shorter life.

Fruits for the Hawaiian Islands, W. T. BRIGHAM (*Hawaii. Forester and Agr.*, 3 (1906), No. 10, pp. 289-311, figs. 2).—In a paper read before the Farmers' Institute of Hawaii brief mention was made of about 100 tropical and subtropical fruits that either have been or should be cultivated in the Hawaiian Islands. The paper is followed by a brief discussion.

Suggestions on the renewal of the peach industry in New Jersey, G. F. WARREN (*New Jersey Stas. Bul.* 197, pp. 46, figs. 19).—During the period between 1890 and 1900 it appears that the number of peach trees in New Jersey decreased 38 per cent, due chiefly to the work of the San José scale but also to poor tillage and other causes. The present bulletin shows the adaptability of different portions of the State to the peach industry and encourages increased planting.

Directions are given for the culture of peaches from planting to marketing, together with results of experiments in planting different kinds of pits, pruning the tops to different degrees at transplanting time, dipping with lime, salt and sulphur mixture, and determining the amount of plant-food removed by a 10-year-old peach tree during its growth.

It appears that about three-fourths of the peach trees of the State are situated on the brownish-yellow, chestnut soils of the hills and mountains of North Jersey. Second in importance to this soil are the gravelly loams of South Jersey. Good peaches are also grown on the sandy trucking soils of the State.

Out of 620 pits of natural seedlings planted 108 trees were secured, while from 321 pits from budded trees only 7 trees were secured, indicating that in nursery work the pits of seedlings are best for growing stocks. One-year-old trees proved better than June-budded trees for transplanting in the orchard. When trees were dug and the roots exposed to the sun for 15 minutes to 1½ hours before planting the number of trees making a good growth was decreased from 33 to 66 per cent. If the trees must be planted when the ground is not moist it is advised that the roots be dipped into water before planting.

Owing to the wide spread of the San José scale it is advised that the tops of the trees be dipped in a lime, sulphur and salt solution before planting. Experiments were made in dipping trees in single and double strength solution, which showed that no injury results unless the buds have started into growth, in which case the buds are killed. If root lice are present the roots of the trees should also be dipped. The trees should be examined for borers and those found dug out. Measurement of the growth of twigs at different periods during the season indicated that about half the growth was completed by the middle of May and about four-fifths by the middle of June, showing that cultivation for the purpose of benefiting the tree should be done early in the season, commencing before the time corn is planted.

The total weight of the wood, prunings, roots, leaves, and fruit produced by a peach tree during 10 years' growth was found to be 616 lbs., of which about 2.8 lbs. was nitrogen, 0.76 lb. phosphoric acid, and 1.7 lbs. potash. It is calculated on this basis that an acre of trees set 16 by 15 ft. would utilize 516 lbs. of nitrogen, 838 lbs. of phosphoric acid, and 307 lbs. of potash in 10 years. The average per acre for the first 4 years would be 33 lbs. of nitrogen, 8 lbs. of phosphoric acid, 18 lbs. of potash, and for the last 6 years 64 lbs. nitrogen,

18 lbs. phosphoric acid, and 40 lbs. potash. The results here given are compared with like data secured at the New York Experiment Station and in Germany and correspond fairly well except in the matter of potash, which was slightly more than half of that reported by other investigators, due to the fact that the tree had produced only a comparatively small amount of fruit. It is stated that before an orchard of peaches is set out in New Jersey the soils in nearly all cases should be limed with 25 to 40 bu. per acre.

Trees at transplanting time were pruned to whips, 1 in. stubs, and 3 in. stubs, and by leaving two-thirds of the top. The trees pruned to whips at the time of planting, 1 in. stubs or 3 in. stubs, did equally well and made better and larger trees by fall than those on which two-thirds of the top was left.

The chief varieties grown in the State appear to be first Elberta, then Reeves Favorite, Mountain Rose, and Chair Choice.

Pruning peach trees, F. HORSEFALL (*Missouri Fruit Sta. Circ. 2, pp. 4*).—Popular directions for pruning peach trees are given.

Culture of the olive, L. DEGRULLY (*Ann. École Nat. Agr. Montpellier, n. ser., 6 (1906), No. 2, pp. 90-160, figs. 15*).—An extensive account of the propagation and culture of olives.

Growth and ripening of persimmons, W. D. BIGELOW, H. C. GORE, and B. J. HOWARD (*Jour. Amer. Chem. Soc., 28 (1906), No. 6, pp. 688-703, figs. 4, dgm8. 4*).—The text is given of a paper presented at the New Orleans meeting of the American Chemical Society held December 30, 1905, an abstract of which has already appeared (*E. S. R., 17, p. 612*). The paper has been reprinted as a separate.

Production and commerce of bananas and pineapples in Western French Africa, Y. HENRY (*Agr. Prat. Pays Chauds, 6 (1906), No. 43, pp. 284-295*).—An account of the suitability of French Guinea for the production of bananas and pineapples, with suggestions on shipping and marketing. Because of the low land values, cheap labor, and cheap water for irrigation, it is believed the country is specially favorable for the production of these tropical fruits.

Culture and commerce of the banana in Costa Rica, JORES (*Agr. Prat. Pays Chauds, 6 (1906), No. 43, pp. 298-303, fig. 1*).—The yearly production of bananas in Costa Rica is placed at 6,000,000 bunches, valued at \$1,160,000. The present article deals with the recent efforts of the government of Costa Rica and the United Fruit Company to develop this industry in the islands. The cost of production is placed at about 10 cts. per bunch.

Analysis of pineapples, G. A. CUADRADO (*Bol. Ofic. Sec. Agr. Cuba, 1 (1906), No. 6, pp. 427-434*).—The results secured in the analysis of pineapples are given, with an account of the chemical methods employed in making the analysis.

New wax article (*Mo. Consular and Trade Rpts. [U. S.], 1906, No. 313, pp. 109, 110*).—An account is given of the wax obtained from rafia palm, the same palm from which is gathered rafia fiber.

The wax is a by-product obtained in the production of the fiber, and has about three-fifths the value of the fiber. In one experiment 104 kg. of leaves gave 0.78 lb. of prepared wax. It is estimated that the average wax production would be about 100 gm. for every kilogram of rafia obtained. It is believed the wax will have a commercial value about equal to that of beeswax.

European grapes, F. GARCIA (*New Mexico Sta. Bul. 58, pp. 32, figs. 6*).—Notes are given on tests of 52 varieties of European grapes, with brief descriptions of the same and directions for the culture of grapes in New Mexico. A discussion on the crown gall diseases of the grapevine, by G. G. Hedgcock, of the Bureau of Plant Industry, is included.

The European or *Vinifera* grapes appear to be well adapted to culture in the Rio Grande Valley, where native or American grapes are but little grown. The Mission is the variety generally grown, but both earlier and later varieties are desirable for prolonging the season. The Chasselas group of grapes appears to be quite resistant to the crown gall, which is a prevalent disease there.

From tests at the station it appears that a rather light soil is preferable to heavy adobe for European grapes. As a protection against winterkilling the vine should be hilled in the fall. Irrigating the hilled vine during the winter was not found to be detrimental. From 4 to 6 irrigations in summer were sufficient to mature a crop.

Wild plant improvement, N. B. PIERCE (*Pacific Rural Press*, 72 (1906), No. 19, pp. 292, 293).—The author states that while there are 895 experiment stations and agricultural colleges and 252 important botanic gardens and arboreta now in the world, not one has been founded for or specifically devoted to the improvement of wild plants. It is believed that there is a large field for useful work in this direction, and in substantiation of this statement the work that might be undertaken with various species of cotton, grapes, figs, persimmons, olives, raspberries and blackberries, chestnuts and walnuts, clovers, millet, grasses, and the various grains, vegetables, flowers, and timber trees is suggested.

All the hollies worth growing, W. MILLER (*Gard. Mag.* [N. Y.], 4 (1906), No. 5, pp. 237-237, figs. 10).—This article sets forth the horticultural value of the various species of *Ilex*, including the red-berried evergreens, the red-berried deciduous species, the scarlet-orange group, and the black-berried group. Cultural directions are given for the various hollies, with a planters' guide to the species. *

Lawns and how to make them, L. BARRON (*New York: Doubleday, Page & Co., 1906, pp. 174, pls. 31*).—This book contains very full directions for the making of large and small lawns, renewing old lawns, fertilizing, grading, and general care of lawns, with accounts of the different species of grasses used for lawns and lawn mixtures, and of the machinery and tools used in the making and caring for lawns.

In the final chapter a tabular presentation is given, showing the essential differences in regard to soil requirements, character and uses, prices, weights, quantities to sow, etc., of 17 standard lawn grasses.

Pot fertilizer experiments with roses, F. WEBER (*Gartenflora*, 55 (1906), No. 20, pp. 529-533).—A fertilizer experiment was carried out with the variety *Fran Karl Druschki*, in which one pot was used as a control, one fertilized with pigeon manure dissolved in water in the proportion of 1:24, each pot receiving about 0.2 of a liter per week; one the same manure in the same proportion and amount per plant plus 3 gm. of sulphate of ammonia, and a fourth fertilized with 2 gm. of nitrate of soda, 1 gm. double superphosphate, and 2 gm. of chlorid of potash, all dissolved in 1 liter of water and applied at the rate of 0.2 of a liter per pot weekly.

The work was carried on at 5 different experiment stations and the results as regards growth, resistance to disease, and the production of flowers recorded for each station. Generally speaking, the smallest growth was made in the control pot. At 3 of the 5 stations the plants fertilized with minerals alone were most resistant to disease and insect attacks, while the average of the results secured at all of the stations showed that the minerals alone produced from 2 to 6 per cent more flowers than were obtained in any of the other pots.

Further development of etherization in the forcing of lilacs, F. LEIEN (*Möller's Deut. Gärt. Ztg.*, 21 (1906), No. 44, pp. 530-534, figs. 4).—An account

of the development of etherization in the forcing of lilacs in Germany is given, with the results of recent experiments by the author.

With the variety Marie Legraye it was observed that by the end of July the flower buds had already formed. When the plants were defoliated at this time and brought in a close, moist, warm air, they blossomed within 4 weeks without etherization. The plants did not blossom any sooner than this when etherized either before or after defoliation, neither did the plants produce bloom when brought into a warm, moist atmosphere unless they were first defoliated. When the plants were defoliated and left in the open, even in warm weather, they did not produce flowers. A moist temperature, as well as a warm one, seemed to be an essential condition of their blooming. It is believed that these observations make an important supplement to the theory of Johannsen on the degree of maturity and rest period of plants.

With the variety Charles X the flower buds did not develop so early nor did they respond when the plant was defoliated in a warm, moist atmosphere, as was the case with Marie Legraye. When this variety was defoliated and etherized July 27, a large number of the uppermost buds were killed, though many leaves were sent out from the lower buds. When etherized with 40 gm. of ether per hectoliter of space, with the leaves on, it produced several well expanded flower clusters 4 weeks later. With Charles X, as with the Marie Legraye, plants neither defoliated nor etherized did not produce flowers even though kept in a warm, moist atmosphere.

The results show that with Marie Legraye it is possible to have flowers from the beginning of August on, and with Charles X from about the first of September. At this time about 40 gm. of ether per 100 liters space can be safely used with the latter variety.

Epsom salts for azaleas, J. C. HOGENSON (*Gard. Mag.* [N. Y.], 4 (1906), No. 5, p. 228, figs. 3).—The author successfully grew azaleas in soils well supplied with lime by the use of sulphate of magnesia to counteract the lime.

In the experiment here reported 2 plants as nearly alike as possible were potted separately in a compost to which nearly a half ounce of lime was added to every 5 lbs. of soil. To one of the pots there was added in addition a quarter of an ounce of sulphate of magnesia to every pound of soil. The flower buds of the plant in the pot to which no sulphate of magnesia was added made a poor development, and finally turned brown and dried up without opening at all, while in the pot in which the sulphate of magnesia was added the plant made a good, vigorous growth and bore and abundance of flowers. Like results were also secured with rhododendrons.

FORESTRY.

Forest planting on coal lands in western Pennsylvania, S. N. SPRING (*U. S. Dept. Agr., Forest Serv. Circ.* 41, pp. 16).—A brief history is given of the original forest conditions of the coal lands in Pennsylvania, with an account of the development of coal mining and its effects on agriculture and forestry in the mining district. The injurious effects on all vegetation of coke production, due to sulphur gas, is briefly mentioned and the opportunity for forest planting on these lands discussed at considerable length.

A planting plan covering 456 acres was made for lands in this area and is given in detail. The plan, it is believed, will be generally applicable to the Connellsville basin in Pennsylvania. The chief trees recommended are red oak, chestnut, white oak, European larch, yellow poplar, hard maple, and hardy catalpa. The plan provides for the growing of nursery trees for restocking

this area. The total outlay per acre for forest planting is placed at approximately \$10.

Special attention is called to insects as obstacles to planting in western Pennsylvania, the more serious of these being a measuring worm and certain insects especially injurious to locust trees.

The utilization of tupelo, H. B. HOLROYD (*U. S. Dept. Agr., Forest Serv. Circ. 40, pp. 16, figs. 4*).—An account is given of the range and distribution of this wood, its uses, methods of logging and milling, the air and kiln-drying. With increasing knowledge as to the best methods of handling this timber has come an extension of the uses to which it is put. In 1905 it is estimated that 40,000,000 ft. of this lumber was cut.

The dry wood weighs about 32 lbs. per cubic foot and the shipping weight varies from 3,000 to 3,500 lbs. per thousand feet. The wood is strong, stiff, tough, and hard to split, but easy to work with tools. It takes glue, paint, or varnish well, absorbing but little of the material. The better grades of the wood are extensively used in England for interior finish and flooring.

Tupelo is much used in this country in the manufacture of boxes, laths, pumps, violin and organ sounding boards, drawers, panels, etc. It promises to be especially useful for tramways and as flooring for depots, warehouses, and other places subject to heavy traffic. As it takes preservatives well it is thought it may find use as cross-ties, street paving, and cross-arms.

Special care must be taken in piling tupelo. The front foundation of the pile should be at least $2\frac{1}{2}$ ft. high and have a slope of 1 in. for each foot of length. The best results have been obtained by making the pile 6 ft. in width and not over 16 or 17 ft. high. Cross strips should be made of thoroughly dry material, $1\frac{1}{4}$ to 2 in. wide and 1 in. thick. An 18-ft. pile should contain 7 of these strips, a 16-ft. pile 6, a 14-ft. pile 5, and a 12-ft. pile 4. The boards should be laid $2\frac{1}{2}$ to 3 in. apart. Between the top of the pile and the roof a space of about 6 in. should be left to admit plenty of air. The roof should extend a foot or two beyond each end of the pile and should be so constructed as to exclude the rain. At least 18 in. should be left between piles.

Experiments show that tupelo can be kiln-dried by the same methods and with the same success as red gum. "The lumber should enter a temperature of about 93° F. at the wet end of the kiln. The temperature gradually increases as the truck moves toward the dry end, where it should stand in a temperature of from 140° F. to 150° F. for 2 or 3 days." The lumber on the kiln truck should be so piled as to leave continuous open spaces in order to give an upward vent and aid the circulation. Tupelo lumber kiln-dried 15 days came out without molding, staining, or stick rotting. The loss in weight was about 33 per cent and the shrinkage in board measure 4.4 per cent.

Grades and amount of lumber sawed from yellow poplar, yellow birch, sugar maple, and beech, E. A. BRANIFF (*U. S. Dept. Agr., Forest Serv. Bul. 73, pp. 30*).—An endeavor was made to determine in typical localities and under good conditions of manufacture the graded yield and money value of yellow poplar, yellow birch, sugar maple, and beech.

The graded yield of yellow poplar was made in both Virginia and Tennessee, and of birch, sugar maple, and beech in the Adirondack hardwoods. In this work the saw crews were followed, the trees and individual logs in the trees measured and marked as they were felled, and the amount and grade of lumber produced by each log determined at the mill. In the case of yellow poplar 5,735 logs from 1,407 trees were thus traced through a Tennessee mill and the logs from 315 trees through a Virginia sawmill. The yield of firsts and seconds, saps, box boards, commons, and shipping and mill culls is shown in tables for

trees of different diameters ranging from 13 to 70 in., as is also the money value of the trees and the value of the lumber per 1,000 ft. Based on this work a log rule is given for southern hardwoods and the method of using in timber cruising the data obtained is described.

In the study of Adirondaek hardwood the inner portion of each 8-ft. log and each 16-ft. log was put into ties, the rest of the log being manufactured into lumber. Twelve and 14-ft. logs were made entirely into lumber. The graded lumber sawed from each of the different species is given in tabular form for trees of different diameters ranging from 13 to 31 in. and the results discussed in detail. The better grades of yellow birch are shown to increase from 13 per cent in a 13-in. tree to 58 per cent in a 31-in. tree, while the poorer grades drop from 86 to 40 per cent between the same diameters.

In a discussion of the profits from Adirondaek lumbering it is shown that if all birch and maple were cut down to and including 19 in. diameters the profits per acre would be \$8.14, of which \$7.48 would be from birch and 66 cts. from maple. Beech would not pay expenses. It is stated that "hardwood lumbering in the Adirondaeks is so expensive that as a rule it does not pay to cut any but the larger trees for lumber."

Cross ties purchased by the steam railroads of the United States in 1905, H. M. HALE (*U. S. Dept. Agr., Forest Serv. Circ. 43, pp. 6*).—Replies from 770 steam railroad companies, representing about 285,000 miles of track, are given, showing the number of cross ties used in 1905.

The total number reported is 77,981,227, of which 18.5 per cent were for use in the construction of new track and the remainder for renewals. Of the total number 44.5 per cent are made from oak and 23.5 per cent from pine. Standing next in importance to these species are cedar, representing about 7 per cent, and chestnut, about 5 per cent. Practically the only region in the United States where ties are produced as a major product of the forest is on the Pacific coast. In the east the farmer's woodlot is the chief source of supply.

Nearly 10 per cent of the ties purchased in 1905 were treated with preservatives. In the southern, lake, and central regions more hewed than sawed ties are used, but on the Pacific coast 82.3 per cent of the ties are sawed.

Experiments on the strength of treated timber, W. K. HART (*U. S. Dept. Agr., Forest Serv. Circ. 39, pp. 31, figs. 2*).—A summary is given of the results secured in an extensive study of methods of the influence of preservative processes upon the strength of woods. The preservatives used were creosote and zinc chlorid. Both green and seasoned timbers were treated in a high-pressure impregnating cylinder. The timbers used were loblolly and western yellow pine railroad ties 11 ft. long. The following conclusions from the work are drawn:

"(1) A high degree of steaming is injurious to wood. The degree of steaming at which pronounced harm results will depend upon the quality of the wood and its degree of seasoning, and upon the pressure (temperature) of steam and the duration of its application. For loblolly pine the limit of safety is certainly 30 pounds for 4 hours, or 20 pounds for 6 hours. (2) The presence of zinc chlorid will not weaken wood under static loading, although the indications are that the wood becomes brittle under impact. (3) The presence of creosote will not weaken wood of itself. Since apparently it is present only in the openings of the cells, and does not get into the cell walls, its action can only be to retard the seasoning of the wood."

Transverse strength of clanwilliam cedar (*Agr. Jour., Cape Good Hope, 29 (1906), No. 4, p. 448*).—Tabular results are given of the tests of a number of beams cut from dry trees of clanwilliam cedar.

Black wattle forestry in South Africa, W. HOLTZ (*Ber. Land u. Forstw. Deutsch-Ostafrika*, 3 (1906), No. 1, pp. 17, pls. 3).—A report is here given of the black wattle industry of South Africa, with an account of the culture, commercial importance, and uses of the forests.

Consumption of tanbark in 1905, H. M. HALE (*U. S. Dept. Agr., Forest Serv. Circ. 42*, pp. 4).—Statistics from 222 firms operating 477 tanneries were obtained, showing the consumption of tanbark in the United States in 1905.

The total amount of bark used during the year is placed at 1,104,045 cords, of which 73 per cent was hemlock and 27 per cent oak. The average price of the hemlock bark per cord was \$6.32 and of the oak bark \$10.44. Pennsylvania produced the largest amount of bark, 428,709 cords, followed by Michigan with 240,653 cords.

Other data show that the extract of quebracho, a tanning product obtained from a South American tree, has greatly increased during the last few years, amounting approximately to 87,000,000 lbs. in 1905, valued at \$2,480,000.

Wood used for pulp in 1905, H. M. HALE (*U. S. Dept. Agr., Forest Serv. Circ. 44*, pp. 11).—A report is made of the quantity and value of wood used for pulp manufacture in 1905.

The wood used for pulp amounts to about 4 per cent of the amount used annually for lumber. In 1905 there were 164 companies operating 237 mills. These used 3,192,223 cords of wood, from which was produced 2,084,482 tons of pulp. The amount of pulp produced from a cord of wood by different methods of manufacture was as follows: Mechanical 2,372 lbs., soda 1,033 lbs., and sulphite 1,009 lbs.

The wood most commonly used for pulp is spruce which in 1905 constituted more than 70 per cent of the total. Next to spruce stands poplar, followed by hemlock, pine, balsam, cottonwood, etc. Most of the wood in 1905 was reduced by the sulphate process, the proportions being sulphite 51 per cent, mechanical 34 per cent, soda 15 per cent. The amount of spruce and poplar imported in 1905 for pulp making was 645,428 cords. New York State leads in the production of pulp and in the importation of wood for this purpose.

The use of slabs for pulp making is reported by 138 establishments. It seldom constitutes, however, more than 10 per cent of the total amount of wood used by a single mill. About 85 per cent of the companies reporting carry on logging operations and only 5 companies depend wholly upon other states or Canada for their supply of wood. The average price of wood f. o. b. at the point of shipment is \$5.55.

The cultivation of *Ficus elastica*, the India rubber of the east, C. BALD (*Calcutta: Thacker, Spink & Co., 1906*, pp. V + 32, pls. 4).—*Ficus elastica* is considered the most promising species for cultivation in Ceylon. The present work is intended as a guide to those contemplating the establishment of rubber plantations and deals with soil, rainfall, elevation, planting, cultivation, etc.

DISEASES OF PLANTS.

A new anthracnose of alfalfa and red clover, S. M. BAIN and S. H. ESSARY (*Jour. Mycol.*, 12 (1906), No. 85, pp. 192, 193).—In a preliminary note on clover diseases (*E. S. R.*, 17, p. 567) the authors announced the discovery of a new clover disease in Tennessee caused by an undescribed species of *Colletotrichum*. Experiments are being carried on to determine the life history of the fungus, as well as breeding experiments with clover to secure resistance to the disease, and pending publication on these experiments the authors thought best to give a description of the species.

Since the publication of the preliminary note on this disease, opportunity has been offered to compare notes and specimens of a similar disease of alfalfa, and so far as the authors' observations go the fungi occurring on clover and alfalfa are identical. On both clover and alfalfa considerable injury is reported, and in the clover fields of Tennessee this disease appears to be the most destructive fungus disease known.

There appear to be in the case of clover 2 critical periods when the plant is especially subject to the disease. The first is when the seedlings encounter the first prolonged hot spell during summer, at which time the disease attacks the petioles. This appears to be the period of greatest injury. The other period of especial susceptibility is during the ripening of the seed, when the severest attacks are observed on the stems just at or slightly below the surface of the ground. Many flower heads are destroyed by attacks just below them, the host plant as a whole appearing usually to survive. The statements given are general in character and more detailed descriptions will be given later.

The name *Colletotrichum trifolii* n. sp. has been given the fungus, a technical description of which is appended.

Indian wheat rusts, E. J. BUTLER and J. M. HAYMAN (*Mem. Dept. Agr. India, Bot. Ser., 1 (1906), No. 2, pp. 1-52, pls. 5*).—According to the authors' investigation 3 distinct species of rust are prevalent in India, black rust (*Puccinia graminis*), yellow rust (*P. glumarum*), and orange rust (*P. triticina*), all three of these species attacking wheat, while barley is subject to attacks of the first 2 species.

In different districts of India the different species found on wheat vary, *P. triticina* being the most common in eastern districts, *P. graminis* in southern, and *P. glumarum* in the northern part. The only intermediate hosts for any of these rusts known in India are the barberries near Simla, which bear the acidia of *P. graminis*.

In India oats are not attacked by the black rust of wheat or barley, the particular physiological race of *P. graminis* which attacks oats apparently not having been introduced.

Studies were made of these different rusts, their distribution, relationship, host plants, etc., and from the data obtained it is believed that it would be possible to begin investigations on the production of resistant varieties of wheat on a rational plan. It is shown that in these breeding experiments the resistance to different species will have to be considered separately, since resistance to one particular rust does not imply resistance to others.

Flower infection by smuts, O. BREFELD and R. FALCK (*Untersuch. Gesam. Geb. Mykol., 1905, No. 13; abs. in Bot. Centbl., 101 (1906), No. 8, pp. 212, 213*).—As a result of prolonged experiments the authors have determined the means of smut infection and dissemination in the case of a number of species.

Infection experiments with loose smut of wheat show that the infection takes place in the flowers and not when the plant is in the seedling stage. The same is true for barley smut, and seed treatment for the prevention of these diseases is worthless. To combat these diseases selected seed from crops that are free from disease is the only practical means, and the seeds should be sown upon smut-free soils.

With oats there seems to be evidence of abundant infection during the seedling stages, and this is also the case with the millet smuts and some other species.

Previous investigations show the infection of corn by means of aerial conidia produced from smut masses in freshly manured soils (E. S. R., 7, p. 693).

Combating the stinking smut of wheat and rye, A. VOLKART (*Landw.*

Jahrb. Schweiz., 20 (1906), No. 8, pp. 445-490, figs. 3).—An extended account is given of experiments in treating seed wheat and rye with various fungicides for the prevention of the stinking smut. The fungicides tested were copper sulphate, Ceres powder, hot water, Bordeaux mixture, soda Bordeaux mixture, and formalin. The effect of these different solutions on the germination of the seed and their efficiency in preventing the smut are described at length.

In conclusion the author states that while all the treatments are more or less efficient, yet for general purposes the use of a solution of formalin is to be preferred.

The relation of the weather to rust of cereals, W. H. MORELAND (*Mem. Dept. Agr. India, Bot. Ser.*, 1 (1906), No. 2, pp. 53-58, *dgm.* 1).—The author has compiled data to show the influence of the character of the season on the rust of cereals: the amount of rain in October, which determines the wetness of the seed bed; the average humidity of January and February, and the average of January and February taken together.

It was found that the amount of October rainfall has no influence on determining the amount of rust on wheat. Where harvest is earliest the extent of rust varies with the humidity during January. Elsewhere the rust varies generally with the humidity of the months of January and February taken together.

The occurrence of a case in which barley was badly rusted while wheat was free from it will require some explanation other than weather relations.

Investigations on the disease of rice called brusone, U. BRIZI (*Ann. Ist. Agr. [Milan]*, 5 (1901-1904), pp. 77-95).—After briefly reviewing the various reputed causes of brusone of rice the author gives an account of experiments carried on with this disease. While he is not able to say definitely what are the causes of the disease, yet from his investigations he concludes that it is primarily due to some functional disturbance of the root system of the plants and is not caused by fungi or other parasites. It seems possible so to disturb the normal activities of the plant as to make it readily attacked by different fungi, but the disease can originate independently of all parasitic attacks.

Some fungus diseases of corn, L. H. PAMMEL (*Iowa Agr.*, 7 (1906), No. 2, pp. 47-50).—Popular descriptions are given of corn rust, bacteriosis, corn wilt, and leaf browning.

Recent investigations on potato and tomato diseases, O. APPEL (*Jahresber. Ver. Vertreter Angew. Bol.*, 3 (1904-5), pp. 122-136, figs. 2).—Notes are given of recent observations on a number of diseases of potatoes. Among them are the speck rot of tubers due to *Stysanus stemonitis*, a disease attributed to *Spondylocladium atrovirens*, injury due to mites, a Fusarium disease, the rot caused by *Phytophthora infestans*, a leaf rolling disease caused by a Fusarium that is said to be similar to but not identical with *F. oxysporum* (E. S. R., 15, p. 1088), a bacterial disease of potatoes, and black shank of potatoes.

The early and late blight of potatoes and how to combat them, W. J. GREEN and C. W. WARD (*Ohio Sta. Circ.* 58, pp. 4).—Descriptions are given of the early and late blight of potatoes and suggestions for their prevention. The circular is issued in advance of a bulletin on the same subject.

Fungus diseases of sugar cane in Bengal, E. J. BUTLER (*Mem. Dept. Agr. India, Bot. Ser.*, 1 (1906), No. 3, pp. 53, pls. 11).—A preliminary report is given of the principal fungus diseases which affect sugar cane in Bengal. The cause and characters of the different diseases are briefly described and recommendations made for combating them so far as means are known.

The diseases described are red rot or red smut (*Colletotrichum falcatum*), smut (*Ustilago sacchari*), *Diplodia cacaoicola*, *Cytophora sacchari*, pineapple disease (*Thielaviopsis ethacetica*), black rot (*Sphoronama adiposum*), brown

leaf spot (*Cercospora longipes*), ring spot (*Leptosphaeria sacchari*), and sooty mold (*Capnodium* sp.). Of these diseases the red rot or red smut is by far the most destructive. The author believes this disease is carried in the majority of cases by cane cuttings that are planted. The selection of sound cane and of resistant varieties, the destruction of diseased material, and the avoiding of ratooning are recommended as possible means of control.

In addition to the above, brief notes are given on a number of other diseases that are not common or are as yet unreported from Bengal, although probably existing there or liable to introduction.

Gumming of the sugar cane, N. A. COBB (*Hawaii, Planters' Mo.*, 25 (1906), Nos. 1, pp. 13-36, figs. 10; 2, pp. 57-68, figs. 2).—This is a reprint of Hawaiian Sugar Planters' Station, Division of Pathology and Physiology Bulletin 3 (E. S. R., 17, p. 778).

Preliminary notes on root diseases of sugar cane in Hawaii, L. L. BRAIN (*Hawaii, Planters' Mo.*, 25 (1906), Nos. 3, pp. 104-121, figs. 11; 4, pp. 153-166, fig. 1).—This is a reprint of Hawaiian Sugar Planters' Station, Division of Pathology and Physiology Bulletin 2 (E. S. R., 17, p. 778).

Pear blight, F. M. ROLFS (*Missouri Fruit Sta. Circ.* 3, pp. 4).—Attention is called to the bacterial blight of pears. The life history of the organism and mode of infection are described and methods of treatment suggested.

The use of Bordeaux mixture for the control of *Cycloconium* on the olive, O. TOBLER and U. ROSSI-FERRINI (*Atti R. Accad. Econ. Agr. Georg. Firenze*, 5, ser. 3 (1906), No. 3a, pp. 327-337).—The results of a series of experiments in spraying olive trees for the prevention of attacks of *Cycloconium oleaginum* are given, which show that while in general the appearance of the tree is improved by the use of the fungicide, yet marked differences are to be noted in the effect on the yield of different varieties. The experiments cover a period of 3 years with a number of varieties, and the results are tabulated.

Treatment for fumagine of olive, D. VIDAL (*Prog. Agr. et Vit. (Ed. l'Est)*, 27 (1906), No. 43, pp. 509-515).—An account is given of experiments that have been carried over a number of years for the prevention of fumagine of olives, and the author states that the most efficient treatment is one that is directed against both the fungus and the insect which it follows.

Spraying the trees with Bordeaux mixture to which either turpentine or a resin soap mixture was added gave splendid results. Where a tobacco decoction was added to the Bordeaux mixture the results obtained were less favorable.

In general, a Bordeaux mixture containing 2 per cent copper sulphate is preferred, and the turpentine may be poured into the preparation, after which it is to be vigorously stirred. The annual or biennial pruning of the trees facilitates the preventive treatment, and it is thought that by continuing it for 5 or 6 years olive orchards could be cleared of these pests.

Notes on gooseberry mildews, E. S. SALMON (*Gard. Chron.*, 3, ser., 40 (1906), No. 1035, p. 294).—The occurrence of the European gooseberry mildew (*Microsphaera grossularia*) on red currants is noted, this fungus having heretofore been reported in Europe as attacking only gooseberries. Attention is also called to the fact that the American gooseberry mildew (*Spharotheca mors-urae*) has been reported during the present season as occurring on red currants in Ireland and in Denmark.

For the prevention of injury by these fungi spraying with potassium sulphid is recommended.

American mildew in Sweden (*Gard. Chron.*, 3, ser., 40 (1906), No. 1033, p. 262).—An account is given of means which have been adopted in Sweden to exterminate the gooseberry mildew (*Spharotheca mors-urae*). The minister of

agriculture has granted a sum of about \$2,250 toward the publication in newspapers of a full description of the disease, with instructions for ridding gardens of this pest.

It is recommended that all infected bushes be dug up and burned and to prevent the spread of the mildew by spraying the bushes with a strong mixture of sulphur. The importation, transplanting, or sale of gooseberry bushes is prohibited until the end of the year 1907. Growers will be compensated for the loss of stock, preference being given those who have cultivated them for nursery purposes.

Attention is called to the fact that this fungus occurs on related species, particularly on some of the currants, and in one instance it is said that the fungus has been found on raspberries.

The American gooseberry mildew in 1906, E. S. SALMON (*Gard. Chron.*, 3, ser., 40 (1906), No. 1036, pp. 301, 302).—A warning is given to English gooseberry growers of the danger of introduction of the American gooseberry mildew (*Spharotheca mors-ura*), which is reported as being very prevalent in parts of Ireland.

Attention is also called to the occurrence of this fungus in Germany and Sweden, and the means that are taken to combat its spread.

A disease of grape stocks, P. MAGNUS (*Ber. Dcut. Bot. Gesell.*, 24 (1906), No. 7, pp. 402-406).—A discussion is given of the reported occurrence of rhizomorphs of *Armillaria mellea* on grape stocks, and the author announces the identification of the basidiomycetes, *Collybia velutipes*, and *Marasmius borealis* on material submitted for study. The latter species is believed to be in all probability a saprophyte.

A new Plowrightia from Guatemala, W. A. KELLERMAN (*Jour. Mycol.*, 12 (1906), No. 85, pp. 185-187, pl. 1).—A disease of the American century plant (*Agave americana*) is described, which attacks the living leaves at a few points, the infection proceeding rapidly until the entire leaf may be involved.

The fungus appears to be an undescribed species of Plowrightia, and the author has designated it as *P. williamsoniana* n. sp. A technical description is given.

A blister blight of tea, H. H. MANN (*Indian Tea Assoc.* [Pamphlet] 3, 1906, pp. 13, pls. 5).—A serious outbreak of blister blight on tea in Upper Assam has drawn especial attention to this disease on account of the completeness of the destruction which it causes in a very short time and of the local character of its appearance.

The disease is caused by the fungus *Erobasidium vexans*, which can be found sporadically on tea leaves throughout the year, but becomes epidemic only from April to June. The infection is carried from season to season by these sporadic leaves, and germination appears to take place only on a wet leaf or stalk. It usually requires about 10 days from germination to become visible on the leaves, and in about 2 or 3 weeks the disease reaches the characteristic white stage.

As a rule the least healthy and vigorous bushes are those most subject to the blight, the best plants generally being less affected, and on this account the author recommends measures that will tend to increase the vigor of the plants.

The occurrence of Lasiodiplodia on cacao and mangoes, VERA K. CHARLES (*Jour. Mycol.*, 12 (1906), No. 84, pp. 145, 146).—A brief account is given of an investigation of diseased wood and fruits of cacao which were sent to this Department from Brazil for examination. Subsequent consignments showed the same disease to be present in San Domingo and also on the fruit of mangoes that probably came from Florida. In both instances the fruits were found

to be infected with a species of *Lasioidiplodia*, but whether the fungus is *L. tuberculata* or a new species is yet to be determined.

It is thought possible that this fungus may be connected with the witches' broom disease, which is so destructive to cacao, but as yet this has not been established by cultural experiments.

A bacterial disease of oleander. C. O. SMITH (*Bot. Gaz.*, 42 (1906), No. 4, pp. 301-310, figs. 4).—An examination was made during the autumn of 1905 of some diseased oleanders which were sent to the pathological laboratory of the University of California.

These plants were affected with large, hard, woody knots on stems and leaves, and their appearance suggested the possibility of their relationship with the olive disease known as olive knot or tuberculosis. Cultural experiments were carried on with the organisms causing the disease and reciprocal artificial inoculations were made from the olive to the oleander. It was found that the disease in both is caused by the same organism. The cultural characteristics of the organisms isolated from both plants are essentially alike in all respects.

The *Alternaria* blight of ginseng. H. H. WHETZEL (*Cornell Countryman*, 4 (1906), No. 2, pp. 33-41, figs. 9).—The cultivation of ginseng, having become of considerable economic importance, has led to a study of a number of diseases, and the author describes the *Alternaria* blight, which has proved exceedingly destructive in some localities. The species of *Alternaria* has not yet been determined, but from experiments it has proved to be truly parasitic and constantly associated with the disease.

A description is given of the effect of the fungus on the host plant, particular attention being paid to the destruction of the seed crop. For the prevention of injury it is recommended that the plants be sprayed with a 4-6-10 solution of Bordeaux mixture, to each 100 gal. of which is added about a gallon of a resin-soda mixture.

Infectious chlorosis of some mallows. E. BAUR (*Sitzber. K. Preuss. Akad. Wiss.*, 1906, No. 1; abs. in *Bot. Centralbl.*, 103 (1906), No. 2, p. 21).—An account is given of experiments with a form of chlorosis observed upon certain species of Malvaceae.

The investigations show that it is infections within certain groups, but no organism of any kind could be found associated with it. The disease is attributed to the probable action of some of the metabolic products of the weakened plant.

A new disease of *Erythrina*. J. M. JANSE (*Ann. Jard. Bot. Buitenzorg*, 2, ser., 5 (1906), pt. 2, pp. 153-197, pls. 6).—For a number of years a destructive disease of *Erythrina*, an important coffee shade tree, has been observed in Java, and studies have been carried on to determine its cause.

The disease has been found to be due to bacteria, the principal point of attack being the roots, but very characteristic effects are produced in the trunk, branches, and leaves. The bacteria seem to secrete two enzymes, one of which attacks the lignified cells, while the other dissolves the cellulose.

Studies upon some chromogenic fungi which discolor wood. G. G. HEDGCOCK (*Mo. Bot. Gard. Ann. Rpt.*, 17 (1906), pp. 59-114, pls. 10, figs. 3; *Jour. Mycol.*, 12 (1906), No. 85, pp. 204-210).—This investigation was undertaken primarily as a study of chromogenic fungi which are concerned in the color reactions which take place in stained timber and also on account of the losses to the lumber industry due to the lowering of the grade of lumber in piles through the action of many wood-staining fungi. Attention has been given not only to those which deeply penetrate wood and stain it, but also to those which discolor it superficially.

In his investigations the author found about 20 species of fungi, and these are grouped according to the effect on the wood as follows: Wood-bleuing fungi—*Ceratostomella* 8 species; wood-blackening and wood-browning fungi—*Graphium* 7 species, *Hormodendron* 2 species, *Hormiscium* 1 species; and wood-reddening fungi—*Penicillium* and *Fusarium* 1 species each. These different species are described at length, technical descriptions of the organisms and their effect on the timber being indicated, and in addition notes are given on a few species which have not been sufficiently studied for definite characterization.

Dilute sulphuric acid as a fungicide, H. KRAEMER (*Proc. Amer. Phil. Soc.*, 45 (1906), No. 183, pp. 157-163, fig. 1).—On account of the efficiency as a fungicide of sulphur when gently heated over steam pipes, the author was led to investigate the action of heat on sulphur and found that when gently heated sulphur gives off large quantities of sulphuric acid. The efficiency of sulphur as a fungicide when used in greenhouses is believed to be due to the sulphuric acid, as relatively little sulphurous acid is formed under greenhouse conditions.

In order to determine whether sulphuric acid has a fungicidal value, the author conducted a series of spraying experiments, a preliminary report of which has already been given (*E. S. R.*, 18, p. 249). Strengths varying from 1 part to 200 to 1 part to 10,000 were used, and the stronger solutions proved to be quite injurious to many kinds of plants. It was found that there was a considerable difference in the resisting power of plants when sprayed in this manner, but most of them could withstand strengths of 1 part to 500 or 1 part to 1,000 without serious injury.

Subsequent to these experiments, an opportunity was offered of treating a rose garden for mildew, in which the bushes were sprayed on 6 successive mornings with a solution containing 1 part of sulphuric acid to 1,000 parts of water. Within a week the mildew had disappeared entirely and the young leaves which were putting forth showed no signs of injury. At the same time a parallel experiment was carried on, using copper sulphate, 1 to 1,000, and roses sprayed with this solution had the tips of the young leaves considerably injured.

During 1904-5 an opportunity was given of testing sulphuric acid, 1 to 1,000, on roses grown in the greenhouse, with the result that the mildew was completely eradicated and the new growth was vigorous.

The author concludes that dilute solutions of sulphuric acid may have a beneficial effect on the plants treated, apart from their fungicidal action. Inasmuch as the antiseptic properties of sulphurous acid are well established, he believes that possibly the combination of sulphurous and sulphuric acid would be more effective than sulphuric acid alone.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Parasitism and mutualism in nature, L. LALOY (*Parasitisme et Mutualisme dans la Nature*. Paris: F. Alcan, 1906, pp. VIII + 284, figs. 82).—In this volume the author has attempted to present a discussion of various interrelations between animals of different groups and between plants and animals. The discussion, therefore, covers parasitism in general, the parasitism of plants upon animals, and of animals on plants, and the various relations which have been demonstrated to exist in the plant and animal generally between individuals of different sorts. The subject of mimicry also receives consideration.

The bird, its form and function, C. W. BEEBE (*New York: H. Holt & Co.*, 1906, pp. XI + 496, figs. 371).—The author has studied the anatomy and

physiology of the bird from the standpoint of the purpose and use of the various structures observed in birds.

The subjects discussed in the volume include the framework of birds, their food, various features of the external anatomy, and numerous anatomical peculiarities observed in various groups of birds with suggestions of the purpose which these structures serve. Attention is given throughout the discussion to the relationship of birds to their environment.

Rabbits and their destruction, W. G. DOWLING (*Agr. Gaz. N. S. Wales, 17 (1906), No. 8, pp. 805, 806*).—The destruction of rabbits is recognized as a difficult problem in those parts of Australia where their numbers have become excessive. In the author's opinion the best results will be obtained by using net fences to exclude them from certain areas and by cutting off the water supply from their habitats during the summer months.

Animal poisons, E. S. FAUST (*Die Tierischen Gifte, Brunswick: F. Vieweg & Son, 1906, pp. XII + 248*).—The literature relating to the various kinds of animal toxins has been systematically consulted by the author and critically discussed in connection with numerous bibliographical references.

In an introductory chapter the author treats of the nature of animal toxins and their effects and therapeutic uses. The greater part of the volume is occupied with specific discussions of the toxins found in mammals, reptiles, batrachians, fish, mollusks, arthropods, worms, echinoderms, and celerenterates. Particular attention is given to the poisons produced by certain snakes and the therapeutic treatment of their bites as well as to bee stings and the toxins contained in fish and mollusks.

Game laws for 1906, T. S. PALMER and R. W. WILLIAMS, JR. (*U. S. Dept. Agr., Farmers' Bul. 265, pp. 54, figs. 4*).—The purpose of this bulletin is to present in a brief form a summary of the game laws of the United States and Canada regulating seasons, shipments, sales, and licenses in connection with hunting. The information along this line is brought down to date to include the laws passed in 1906.

Zoological yearbook, 1905, P. MAYER (*Zool. Jahresber., 1906, pp. VIII + 560*).—As in previous reports by the author the zoological literature of 1905 is reviewed in a systematic manner in connection with elaborate bibliographies.

Some results of experiment station work with insecticides, E. V. WILCOX (*U. S. Dept. Agr., Office Expt. Stas. Rpt. 1905, pp. 239-280*).—A summary account is given of the more important contributions of experiment station entomologists to the study and practical application of standard insecticides, particularly lime-sulphur-salt wash, petroleum oils, hydrocyanic-acid gas, arsenicals, and soaps, as well as special insecticide methods.

Proceedings of the eighteenth annual meeting of the Association of Economic Entomologists (*U. S. Dept. Agr., Bur. Ent. Bul. 60, pp. 206, pls. 3, figs. 10*).—Most of the articles printed in these proceedings have already been noted in an account of the meeting at which the papers were read (*E. S. R., 17, pp. 619-621*). The following notes are on papers or discussions which have not previously been noted.

A report was submitted by the committee on nomenclature (pp. 25-28). This committee presented a list of the more important injurious insects with their preferred common and scientific names for the purpose of securing uniformity among entomologists in the use of these names.

A paper by P. V. Theobald contained a discussion of the currant root-aphis (pp. 166-170). *Schizoneura fodicus* attacks the roots of the currant, causing galls which somewhat resemble those of the woolly aphis. The biology of the pest is described. The best treatment is to be found in the use of bisulphid of carbon.

C. Fuller in a paper on The Plague Locust of Natal (pp. 171-174) referred to the work which has been done in Natal in controlling *Acridium purpuriferum*. The best poison for these pests appears to be arsenite of soda at the rate of 1 lb. and sugar 4 or 5 lbs. per 15 gal. of water.

The feeding habits of *Lepisma saccharina* were studied by H. Garman (pp. 174-176). According to the speaker's experiments the silver-fish does not feed upon starch or sugar, but preferably upon animal products, such as glue used in binding books and in the mounting of photographs. Occasionally silk is attacked by the silver-fish, but this is also an animal product of a nitrogenous nature.

Twenty-first report of the State entomologist on injurious and other insects of the State of New York, 1905, E. P. FELT (N. Y. State Mus. Bul. 104, pp. 45-186, pls. 10, figs. 48).—As is customary in these reports, a brief account is presented of the general features of entomological work during the season.

The author has continued to give attention to the grape rootworm, and finds that by the thorough application of arsenicals, combined with the use of beetle catchers and with cultivation of the soil to kill the pupae, badly infested vineyards may be protected until they recover from the attacks of the grape rootworm. In some cases, however, vineyards have practically been ruined by this pest. The insect is more injurious on loose sandy soils than on heavy clay soils. The use of arsenicals alone will ordinarily not give complete satisfaction.

An account is also presented of outbreaks of the army worm and of the life history and injurious attacks of various species of grass webworms belonging to the genus *Crambus*. In fighting the San José scale, lime-sulphur washes were used as prepared according to 11 different formulas. The general results were very similar where external heat was applied in preparing the wash, but the author prefers a formula calling for 20 lbs. of lime and 15 lbs. of sulphur in 50 gal. of water, boiled at least 30 minutes.

During the season notes were made and are recorded in the report on codling moth, apple maggot, rose beetle, scurfy scale, white grubs, and various insect pests of shade and forest trees. The shade-tree problem of the State is discussed, with especial reference to the insects which are concerned in injuring these trees. A test was made of the Caucasian bee. This bee appeared to be quite healthy and reasonably gentle, but was not received early enough in the season to give it a fair test.

The mosquito problems of the State are also mentioned with reference to campaigns of draining and insecticide work against these pests. A number of gall insects are described and notes given on the malformations caused by these insects on various plants.

Report of State entomologist of Georgia for 1905. The crop pest law of Georgia, R. I. SMITH (Ga. Bd. Ent. Bul. 20, pp. 161-195).—During the year under report considerable inspection work was done and entomological information was also spread through the agency of farmers' institutes. Particular attention is given in this report to a discussion of the most important insect enemies of peach, apple, pecan, cotton, grain, and garden crops.

A copy is also given of the crop pest law of Georgia and of the regulations of the Georgia State Board of Entomology.

Means of combating grain insects, I. F. HOFFMAN (Illus. Landw. Ztg., 26 (1906), No. 80, pp. 690-692, figs. 6).—Notes are given on the habits and injurious attacks of a number of grain insects, particularly the granary weevil.

In combating these pests the author has had the best success from the use of carbon bisulphid and anilin milk. The carbon bisulphid proved effective in

all cases, but was subject to some disadvantages as compared with anilin milk. The latter preparation is made by adding anilin oil to water in the proportion of 1:15. The mixture is then sprayed or painted on the cracks and walls of the granary and the fumes produced exercise a fatal effect upon insects for a long time thereafter. The author states that it is perfectly safe for human beings to work for a period of 2 hours in the fumes produced from such treatment, but that a longer period might cause nervous disturbances or other signs of poisoning.

The brown-tail moth and how to control it, L. O. HOWARD (*U. S. Dept. Agr., Farmers' Bul. 264*, pp. 22, figs. 10).—A general account is presented of the introduction, distribution, appearance, and life history of the brown-tail moth with particular reference to injury to forest and other trees and the effect produced by the barbed hairs of the caterpillars upon the skin of human beings.

Among the natural enemies of this pest a number of birds are mentioned, particularly cuckoos, orioles, vireos, and blue jays. Native parasites are known to attack them and recently an effort has been made to introduce European parasites. It is too early to predict the results of this importation.

In combating the pest by artificial remedies the best results follow the practice of destroying the caterpillars in their winter nests. These webs or nests may be readily observed as soon as the leaves fall and should be removed before the caterpillars again become active in the spring. If this is not done resort should be had to arsenate of lead or Paris green. The essential features of the recent Massachusetts law regarding the brown-tail moth are given.

Codling moth and fruit fly, A. H. BENSON (*Queensland Agr. Jour.*, 17 (1906), No. 3, pp. 155-157).—While the codling moth is not excessively injurious in Queensland, it is generally distributed throughout the colony, and the author believes that it can not be eradicated. For controlling the pest a destruction of infested fruit and spraying with arsenicals are recommended.

It is believed that the control of the fruit fly can only be accomplished by growing the best varieties of fruit which will pay for the expenditure of time and energy in their care. All infested fruit must then be gathered and destroyed.

Two important scale insects and their control, W. T. CLARKE (*Alabama College Sta. Circ. 1*, pp. 8).—Attention is called to the increasing development of the fruit industry in Alabama and to the injuries caused to this industry by the San José scale and the new peach scale.

The same method of attack is available for both of these pests. For this purpose the author recommends the use of lime-sulphur-salt wash prepared according to the formula 30-20-5-60.

A new Retinia attacking Austrian pine, A. COSENS (*Canad. Ent.*, 38 (1906), No. 11, pp. 362-364).—*Retinia austriana* is described as a new species. The insect is said to attack Austrian pine by burrowing in the cortical layer of the tree and thus piercing the resin ducts and causing an exudation of gum. The injury to infested trees is quite serious, although the pest is partly controlled by parasites.

Mealy bugs, W. W. FROGGATT (*Agr. Gaz. N. S. Wales*, 17 (1906), No. 8, pp. 770-779, pl. 1).—Particular attention is given to a discussion of the appearance and habits of various species of *Monophlebus*, *Pallaooccus*, *Icearya*, and *Callipappus*.

A revision of the Tyroglyphidæ of the United States, N. BANKS (*U. S. Dept. Agr., Bur. Ent. Bul. 13, tech. ser.*, pp. 34, pls. 6).—A number of the species of mites belonging to this family attack stored food products or living plants,

while others are parasitic on injurious insects. The group is, therefore, of considerable economic importance.

Analytical tables are presented to assist in the identification of genera and species, and all species known to occur in the United States are described. A number of these are described as new.

The wing veins of insects, C. W. WOODWORTH (*Univ. Cal. Pubs., Ent., 1* (1906), No. 1, pp. 152, figs. 101).—The views which have prevailed regarding the origin and homology of insect wings have been greatly at variance, and the author therefore undertook a comparative study of this problem for the purpose of presenting, if possible, a more satisfactory system of classification. The development of the wings and veins was given careful attention, and the origin and position of the veins are discussed for each order of insects. The author's views are compared with those of other investigators, and a bibliography of the subject is appended to the bulletin.

The conclusions reached from this study are that the wings are developed purely as a means of flight and that the dominant factors in their development are mechanical necessities. These factors determine the location of the wings and of the veins, the position of the latter being quite different in different orders of insects. It is believed, therefore, that it is not possible to maintain a strict homology in any wing vein throughout the whole series of insects. The author proposes, nevertheless, to use general terms for these veins in a somewhat elastic manner, recognizing the fact that veins of the same name may not be strictly homologous.

Introduction of parasites, C. HARPER (*Jour. Dept. Agr. West. Aust., 14* (1906), No. 3, pp. 175-178).—A controversy having arisen regarding the desirability of expending money in the collection of parasites, the advisory board of the department of agriculture of Western Australia investigated the matter and reports that, in their opinion, the evidence thus far accumulated is in favor of putting forth a reasonable amount of effort to secure all possible parasites of the more important injurious insects.

Some flagellate forms found in the intestinal tracts of diptera and other genera, A. LINGARD and E. JENNINGS (*London: Adlard & Son, 1906, pp. 25, pls. 5*).—A microscopical examination was made of the intestinal contents of the common house fly, *Stomoxys calcitrans*, mosquitoes, and other insects. In this study particular attention was given to the morphology of the flagellate organisms found in the intestines of flies and upon the influence of the food which they received upon the number and character of these organisms.

The breeding habits of the tsetse fly, E. A. MINCHIN (*Nature [London], 74* (1906), No. 1930, p. 636).—The author quotes from the letter of A. G. Bagshawe a statement that the latter has succeeded in finding the pupæ of tsetse flies in the soil about the roots of bananas in a large plantation.

Observations indicate that the adults can fly to a distance of 1 mile from the place where they originate.

The extirpation of the tsetse fly, E. A. MINCHIN (*Nature [London], 75* (1906), No. 1932, p. 39).—The presence of the tsetse fly in considerable numbers was noted in a locality where banana plantations were supposed not to exist. Later such plantations were found, and the author suggests that if the tsetse fly breeds only in banana plantations it might be practicable to combat them by introducing jungle fowl and other birds which would feed upon them in such places.

Analyses of Paris green, J. P. STREET (*New Jersey Stas. Bul. 195, pp. 12*).—A copy is given of the law of New Jersey regulating the sale of Paris green. In accordance with this law, 30 samples of Paris green were analyzed and 20

were found to be of undoubted purity. No sample contained more than 3 per cent of free arsenious acid, but 3 samples did not contain the required 50 per cent of arsenic in combination.

The requirements of the law are so moderate that it is believed all manufacturers can easily conform to them by giving attention to the matter.

Report of the inspector of fumigation appliances, 1905, P. W. HODGETTS (*Toronto: Ontario Dept. Agr., 1906, pp. 7*).—An inspection was made of the larger nurseries in the province of Toronto. In some localities the San José scale is spreading rapidly and effective means have not been taken for controlling it. In general the fumigation appliances of the various nurserymen were found to be satisfactory.

Report of the commission on the rearing of silkworms for 1905, GOMBROT (*Ann. Soc. Agr. Sci. et Indus. Lyon, 1905, pp. 340-346*).—The members of the commission appointed for the encouragement of the silk industry report that they have traveled quite extensively throughout the territory under their supervision and have assisted in furthering the industry of raising silkworms by expert advice and the use of government subsidies allowed for this purpose.

The production of silk and other details are presented in a tabular form.

FOODS—HUMAN NUTRITION.

Standards of purity for food products (*U. S. Dept. Agr., Office Sec. Circ. 19, pp. 19*).—The food standards given are intended to supersede and supplement those contained in publications previously noted (E. S. R., 16, p. 894; 17, p. 1096).

Standards for tea and coffee have been added and some additions have been made to the standards previously published for meat and meat products, milk and milk products, fruit and fruit products, flavoring extracts, and edible vegetable oils and fat, and a few modifications have also been made in the text.

Rules and regulations for the enforcement of the Food and Drugs Act, L. M. SHAW, J. WILSON, and V. H. METCALF (*U. S. Dept. Agr., Office Sec. Circ. 21, pp. 20*).—The rules and regulations recommended by the committee appointed from the Departments of the Treasury, Agriculture, and Commerce and Labor regarding the enforcement of the Food and Drugs Act, approved by Congress June 30, 1906, are embodied in this circular, as well as the full text of the Food and Drugs Act.

Some experiment station work relating to the food and nutrition of man, R. D. MILNER (*U. S. Dept. Agr., Office Expt. Stas. Rpt. 1905, pp. 225-237*).—Attention is directed to the large amount of work which has been done by the experiment stations, aside from that carried on in cooperation with the nutrition investigations of the Office of Experiment Stations. Numerous examples of the work are cited, particularly of studies pertaining to production and distribution of food, improvement in yield and quality of cereals, improvement in character of dairy products, food preservation and preparation, and food adulteration.

“Although the stations have already performed in the aggregate a large amount of work along the lines referred to in the present article and in related lines not mentioned, the indications are that similar work will be undertaken still more extensively in the future. For example, there is a growing opinion that the energies of the station should be directed toward the solution of the problems of the various industries for the utilization of farm crops as well as toward the production of the crops; that more attention should be devoted, for instance, to the study of the technology of the preparation and preservation

of butter, cheese, evaporated fruits and canned goods, macaroni, and other prepared cereal products, etc. Studies on canning and preserving, the manufacture of special cereal foods, and other lines of work which have to do with the preservation and distribution of food products bear an important relation to both producer and consumer."

The nutritive value of bread as compared with breakfast foods, R. HARCOURT (*Amer. Food Jour.*, 1 (1906), No. 10, pp. 18, 19).—Results of digestion experiments with corn meal farinas and several commercial breakfast foods are reported and compared with average results obtained by other investigators with cereal goods and with bread.

The author concluded that the special foods studied were less thoroughly digested than white bread. From the data presented it is evident, in his opinion, "that corn meal, rolled oats, and bread are among our most economic foods. It is, however, true that rolled oats, or even the farinas, do not agree with everyone, and that the predigested goods may be useful food for people who have difficulty in digesting starch. They may also have a place in a hurry-up breakfast. It is evident that a curious name of a much advertised food does not indicate a high nutritive value, and the intelligent buyer who has to consider economy will hardly pass by the old forms of breakfast foods and bread unless their own actual experience has demonstrated that these newer foods have a superior value to them."

A proposed method for examining bleached flour, R. H. SHAW (*Jour. Amer. Chem. Soc.*, 28 (1906), No. 6, pp. 687, 688).—The commercial processes for bleaching flour artificially very generally make use of the higher oxides of nitrogen, and when devising a method for the detection of bleaching it was assumed that some nitro body might exist either as residual nitric oxid or as a nitro starch compound.

The proposed method consists in extracting the flour with boiling alcohol, cooling, filtering, evaporating nearly to dryness, extracting the residue with a mixture of equal parts of alcohol and ether, and filtering. The filtrate is evaporated to a sirup-like consistency and distributed in a film over the porcelain dish used and a drop of sulphuric acid solution of diphenylamin is allowed to trail over the film. In the tests reported this left a blue path in every case where the flour used had been artificially bleached, while no coloration was perceptible in unbleached flour.

"A flour bleached by a process using ozone alone as a bleaching agent would probably not respond to the diphenylamin test. Such a process, however, is not used in the West to the writer's knowledge. It is also possible, but highly improbable, that a flour might be found which, fresh from the wheat, would yield the blue color when tested. To decide these points a much larger number of samples will be examined."

A contribution to the history of the use of bark bread, F. T. DILLINGHAM (*Bul. Bussey Inst.*, 3 (1906), pt. 5, pp. 120-128).—The inner bark of trees, particularly conifers, has been frequently used by inhabitants of northern countries as a food in times of dearth. The data on the subject are summarized, as well as the results of studies of nine samples of bark.

It was found that the barks apparently contain decidedly smaller quantities than wood of mannan (the constituent on which it was assumed the food value would depend). "It is not to be denied, as yet, that the mannan in bark bread may be of real importance for human sustenance; but, to all appearance, further work will be needed to account completely for the physiological significance of this kind of food."

Rolled oats, T. MACFARLANE (*Lab. Inland Rec. Dept. [Canada] Bul.* 127, pp. 12).—To determine whether the flaked and rolled oats manufactured and sold

in Ottawa were of inferior quality, as had been claimed, 155 samples were collected and analyzed.

Of these 64 samples showed a crude fiber content higher than 2 per cent, "and this would seem to indicate that with regard to 11.3 per cent of the oat-meal samples now offered for sale in the Dominion the quality might be improved. At the same time none of the samples were found to contain the large amount of oat hulls originally complained of, and in the absence of any standard, it is impossible to characterize any of the samples as adulterated."

From fuller analyses which were made of a number of the samples it appeared that the oat-meals contained on an average 12.3 per cent protein and 4.67 per cent fat.

Experiments with simple food stuffs, L. JACOB (*Ztschr. Biol.*, 48 (1906), No. 1, pp. 19-62).—Previous investigations on animals fed with single food stuffs, although contradictory in some ways, in general led to the conclusion that as compared with the ordinary mixed diet such a diet is harmful, the absence of appetizing qualities in the diet rendering it monotonous and unpalatable.

In the investigations reported starch, olive oil, casein, sugar, salts, and crude fiber were among the materials employed. No bad results followed the use of a diet of such foods in experiments with pigeons and rats. The author notes, however, that appetite is very important and that often animals used for experimental purposes refuse food, lose weight, and even die on a diet which is nutritious, but which has become unpalatable.

Is freshly slaughtered beef palatable and wholesome? J. HLADIK (*Ztschr. Hyg. u. Infektionskrankh.*, 54 (1906), pp. 130-146; *abs. in Ztschr. Fleisch u. Milchhyg.*, 17 (1906), No. 1, p. 23).—Numerous and long-continued experiments led the author to conclude that cooked meat eaten in considerable quantity did not produce any digestive disturbance and that freshly slaughtered meat was palatable if well prepared.

Canned meats, T. MACFARLANE (*Lab. Inland Rev. Dept. [Canada] Bul.* 123, pp. 26).—Of the 322 samples of canned and potted meats and similar products examined 15.8 per cent were found to contain boric acid. This was the only preservative identified, though others were looked for. The quantity found was small "not exceeding the limit fixed by the English parliamentary commission of 0.5 per cent," and was probably added in the form of borax.

Potted meats and bologna sausages, T. MACFARLANE (*Lab. Inland Rev. Dept. [Canada] Bul.* 125, pp. 10).—Microscopical examination showed the presence of foreign starch and consequently cereal meal of some sort in 90 samples of potted meats referred to in an earlier bulletin (see above).

The author points out that such addition can not be considered adulteration if the fact is indicated by the name of the article. "It may be that this is done by the use of the word 'loaf' in a great many instances. But the words 'potted,' 'deviled,' etc., do not justify the addition of flour or corn meal, and articles with such names can not be regarded as otherwise than adulterated if they have received additions of cereal products."

Data are also given regarding the composition of commercial goods containing cereal products intended for use in the manufacture of potted meats and similar products.

Only one of the samples of potted meats was found to contain foreign coloring matter. Of 32 samples of bologna sausage examined, 5 contained added preservatives and 11 artificial dyes.

Experiments on the digestibility of fish and poultry, R. D. MILNER (*Connecticut Storrs Sta. Rpt.* 1905, pp. 116-142).—Following the usual methods the digestibility of canned salmon, fresh cod steaks, canned chicken, and fresh roast duck were studied with 4 healthy men as subjects, the special foods fur-

nishing an integral part of a simple mixed diet. The digestibility of the fish and poultry alone was calculated; the average results follow:

Coefficients of digestibility of fish and poultry—average of four tests.

Kind of food.	Protein.	Fat.	Energy.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Salmon (canned).....	96.23	97.01	85.63
Cod.....	95.93	97.40	80.27
Chicken (canned).....	96.74	97.13	85.35
Duck.....	94.66	97.32	91.14

"From the results of 16 experiments in which canned salmon, fresh cod, canned chicken, and roast duck made up in turn a considerable portion of the diet, it appears that these foods are very completely digested, the coefficients of digestibility being approximately those previously found for other animal foods. The foods containing a considerable proportion of fat were apparently as completely digested as those in which the percentage of fat was relatively small. The number of kinds of poultry and fish investigated and the number of experiments carried on with each are too small to warrant further conclusions."

Composition of tamarind pulp, O. REMEAUD (*Jour. Pharm. et Chim.*, 6. ser., 23 (1906), No. 9, pp. 424-430).—Analyses were made of commercial crude and purified tamarind pulps and of pulp prepared by the author from fruit collected at Saigon.

The "dry extract" ranged from 62.8 to 73 per cent, the ash from 2.8 to 3.3 per cent, and the total acidity, calculated as tartaric acid, from 11.7 to 15.9 per cent. Tartaric acid, acid potassium tartrate, and invert sugar were identified as prominent constituents of the fruit.

Coffee, coffee products, and coffee surrogates, E. FRANKE (*Kaffee, Kaffee-konserven und Kaffeesurrogate*, Vienna and Leipzig: A. Hartleben, figs. 32; *rev. in Österr. Chem. Ztg.*, 9 (1906), No. 20, p. 281).—The preparation of coffee for the market is described, as well as the manufacture of coffee products and of coffee substitutes from figs, grains, malt, etc.

Preserved food products, J. DE BRÉVANS (*Les conserves alimentaires*, Paris: J. B. Baillièrè & Sons, 1906, 2. ed., pp. VIII + 467, figs. 74).—This handbook discusses the general principles of food preservation, the preservation of products of animal and vegetable origin, adulteration of products made from meat, milk, butter and eggs, vegetables and fruits, and the analysis of preserved foods.

Food preservatives, A. MCGILL (*Lab. Inland Rev. Dept. [Canada] Bul.* 126, pp. 32).—Data regarding the character and effects of food preservatives are summarized and discussed, such a collection of information being regarded as a necessary preliminary to the making of regulations under the provisions of the Canadian Adulteration Act regarding the limits within which preservatives may be used.

General results of the investigations showing the effect of salicylic acid and salicylates upon digestion and health, H. W. WILEY (*U. S. Dept. Agr., Bur. Chem. Circ.* 31, pp. 12, fig. 1).—Elaborate studies were made of the effects of salicylic acid taken with food for a period of 30 days, the experimental period being preceded and followed by normal periods of 10 days' duration. Salicylic acid was given in small and increasing doses, beginning with 0.2 gm. and increasing to 2 gm. per day. The diet was varied so as to give a choice of meats and vegetables with bread, butter, milk, coffee, and tea. Foods of the best quality and free from added preservatives or coloring matter were used.

The young men who served as subjects were under medical supervision during the entire experimental period. The amount and composition of the excreta were determined and the food products were analyzed. Special studies were made of the sulphur occurring in the urine, and especially of the relation of sulphur compounds to nitrogen. Microscopical studies were made of the urine and of the blood, and "all possible precautions, in view of the magnitude of the work, were observed in securing a complete chemical and clinical control of each one of the young men engaged in the experimental work." The general deductions are based on results obtained with 9 subjects.

The data reported "show very clearly that salicylic acid and salicylates appear to exert an exciting influence upon the activities which take place in the alimentary canal, stimulating the organs to greater effort, and this stimulation leads at first to increased digestion and absorption of the foods which are introduced into the stomach. In the light of the data which are exhibited salicylic acid may be said to increase the solubility and absorption of the food in the alimentary canal, so that larger parts of the nutrients taken into the stomach actually enter the circulation." This belief "is perhaps to a certain extent undeserved."

"This work is offered as an unbiased study of all the data recorded, both of those which appear to be in favor of the use of salicylic acid and those which appear to be against its use, and leads to the inevitable conclusion that salicylic acid is a substance which, when added to foods even in small quantities, exerts a depressing and harmful influence upon the digestion and health and the general metabolic activities of the body. Further, there appears to be no necessity for its use, as food can be preserved in unobjectionable ways without its aid. Its indiscriminate use would tend to carelessness in the quantities employed, thus increasing the dangers to which the consumer is subjected. Also its use in the preservation of foods tends to induce carelessness and indifference on the part of the manufacturer, as when a chemical antiseptic is employed many of the processes necessary to the proper selection, cleaning, and preservation of foods may be omitted. The addition of salicylic acid and salicylates to foods is therefore a process which is reprehensible in every respect and leads to injury to the consumer, which, though in many cases not easily measured, must finally be productive of great harm."

It was found on an average that the dry matter of the food consumed was equivalent to 0.9 per cent of the body weight.

Diet and dietetics, A. GAUTIER, edited and trans. by A. J. RICE-OXLEY (*London: Archibald Constable & Co., Ltd., 1906, 2. ed., pp. XII+552, figs. 10*).—In this general treatise on food and nutrition the author considers the principles which underlie the subject, methods of experimenting, characteristics of the nutritive value of different foods, diet in different circumstances of health and disease, and related questions. Many of the author's investigations are summarized and numerous references are made to the literature of the subjects discussed.

Food and dietetics, ALICE P. NORTON (*Chicago: American School of Household Economics, 1905, pts. 1, pp. 1-61, figs. 9, charts 4; 2, pp. 62-116, figs. 10, chart 1; 3, pp. 117-187, figs. 16*).—The proportion of total income expended for food and in other ways, characteristics of different animal and vegetable foods, composition and digestibility of food, special diets, dietaries, and dietary standards, and related questions, are discussed in the form of a series of lessons designed for instruction by correspondence.

Accuracy in dietetics, D. ROBERTS (*Jour. Amer. Med. Assoc., 46 (1906), No. 16, pp. 1162, 1163*).—In order to facilitate the calculation of the nutritive value of rations the author has prepared a table showing the weight, protein content,

and fuel value of household measures (glassful, teaspoonful, tablespoonful, etc.) of a number of common food materials.

Dietary studies of a week's walking trip, H. L. KNIGHT (*Connecticut Storrs Sta. Rpt. 1905, pp. 143-163*).—An account was kept of the food eaten by 2 young men during a 7 days' walking trip. Each carried about 25 lbs. of luggage and covered about 20 miles per day.

Generally speaking the foods selected were those supplying nutritive material in small bulk. One of the subjects obtained on an average 86 gm. protein and 3,189 calories of energy per day and the other 56.6 gm. protein and 1,866 calories of energy.

A portable ration for soldiers in battle and on the march, L. L. SEAMAN (*Jour. Amer. Med. Assoc., 46 (1906), No. 21, pp. 1606-1608*).—An efficient ration for soldiers in battle and on the march, it was pointed out, must furnish proximate constituents in necessary proportion, must be easily digested and palatable, and have a minimum waste.

In the author's opinion, smoked beef is a valuable constituent of such a ration as it is easily digested and palatable, may be eaten raw or cooked, and does not become distasteful as soon as canned roast beef or corned beef. For the carbohydrate constituent of the ration he suggests a mixture of 7 parts rice and 3 parts barley meal, cooked, dried, and ground. Tea or coffee is regarded as an essential part of the proposed ration, which also includes sugar, chocolate, salt, and pepper. The calculated protein content is 93.29 gm. and the energy value 2,672 calories.

The nutritive requirements of the body, F. G. BENEDICT (*Amer. Jour. Physiol., 16 (1906), No. 4, pp. 409-437*).—A general discussion of theories of metabolism with special reference to recently published work of a number of investigators.

The author concludes that the evidence which has been presented is far from sufficient to warrant the assertion that the amounts of protein ordinarily consumed should be permanently and materially diminished, and believes that there is evidence to show that permanent reductions are decidedly disadvantageous and, indeed, not without possible danger.

Basing his deductions upon the results obtained by the respiration calorimeter (E. S. R., 15, p. 698) and the fact that the law of the conservation of energy obtains with the animal body, the author points out that the energy intake can be diminished only as the energy output or the muscular activity is diminished. "These facts make any proposition to lower food consumption unaccompanied by decreased muscular activity impracticable."

ANIMAL PRODUCTION.

Live stock (*Quart. Rpt. W. Va. Bd. Agr., 1906, No. 3, pp. 132, figs. 33*).—A number of papers by different authors on the feeding and care of live stock, diseases and their treatment, and related questions, and a summary of the laws of West Virginia relating to infectious and contagious diseases of animals.

Storage barn, sheds, feed lots, and other equipment for feeding experimental cattle in carload lots, H. W. MUMFORD and E. S. GOOD (*Illinois Sta. Bul., 110, pp. 303-324, figs. 6, dym. 9*).—The general plan of the experimental plant used at the station for beef cattle feeding experiments is described and a detailed description given of the construction of the storage barn, methods of preparing and handling feed, and of the construction and operation of the feed lots, the sheds and feed carrier system and of the corn crib and engine house, as well as a general summary of the cost of the plant as a whole.

"The general plan of the experimental feeding plant at this station, for the feeding of 200 head of beef cattle in carload lots, and individually, consists of a storage barn facing east and west and two rows of feed lots connected by a paved alley, lying east and west from the west side of the storage barn. South of the feed lots is a corn crib 144 feet in length, and north of the storage barn is a 20 by 28 foot engine house. On the west side of the barn and north of the alley are stock scales.

"There are twelve feeding lots in the two rows mentioned, seven of which are situated on the south side of the alley and five on the north side. All face to the south and all are paved with brick with the exception of three lots on the north side of the alley, one of which is used for experimenting with cattle fed in an ordinary earth lot. The sheds on the south side of the alley are open on the south side, while those on the north side are inclosed and provided with large sliding doors. None are paved.

"Feed carriers convey the concentrates and chaffed roughage from the second floor of the storage barn to the lots on the south side of the alley."

Maintenance rations for beef-breeding cows, H. W. MUMFORD (*Illinois Sta. Bul. 111, pp. 324-342, figs. 4*).—Using 3 lots of 10 grade cows 3 to 6 years old, corn silage, shock corn, and corn stover were compared with a view to securing data regarding the relative value of cheap feeds available on Illinois farms for maintaining beef-breeding cows during the winter season. The corn feeds were supplemented by clover hay and oat straw, except that for about the first two-thirds of the period no clover hay was used in the corn-stover ration.

To determine whether ensiling the corn is more valuable for winter feeding than curing it, the amount of corn and its accompanying coarse fodder was made the same in the silage and shock corn rations. "In the selection of the feeds to be fed, an effort was made to use such as are not looked upon as cash crops of the farm, but more in the nature of by-products of low commercial value."

In 140 days the average gain on the silage ration was 1.07 lbs. per cow per day, the amounts eaten being 16.65 lbs. silage, 3.5 lbs. clover hay, and 9.56 lbs. oat straw. On shock corn the gain was 0.758 lb. per cow per day, the feed eaten being 8.7 lbs. shock corn, 3.5 lbs. clover hay, and 10.83 lbs. oat straw. On corn stover the gain was 0.41 lb. per cow per day, the feed eaten being 21.67 lbs. corn stover and 5.15 lbs. oat straw when the cows received no clover hay, and when stover hay was used 10.29 lbs. corn stover, 1.56 lbs. clover hay, and 8.19 lbs. oat straw.

As the experiment progressed the cows fed silage and shock corn were in better condition and more contented than those fed the corn stover, and, furthermore, the character of the feces indicated that in the latter case there were digestive disturbances. No such disturbances were noted with the cows fed the silage and the shock corn.

"The corn plant, fed either in the form of shock corn or silage, supplemented with a limited amount of clover hay, proved satisfactory rations for wintering beef-breeding cows." "Under the conditions of this experiment, silage produced 41 per cent greater gain in live weight than an equal acreage of shock corn."

For a part of the test the cows were allowed free access to loose salt, and a record was kept of the amount consumed. The average daily consumption was 0.08 lb. on the silage ration, 0.12 lb. on the shock-corn ration, and 0.10 lb. on the corn-stover ration.

Two of the cows fed corn silage and 2 fed shock corn dropped calves and were removed from their respective lots. At the end of the test the oldest calf was 70 days old, and in no case had they been given other feed than the milk of

their dams. The average gain of the calves ranged from 1.49 lbs. per head per day to 1.98 lbs., both extremes being found with calves from the corn silage lot. The average daily cost of keeping the silage-fed cows which calved was 7.56 cts. and those fed shock corn 6.84 cts. Before calving the average daily cost was 5.8 cts. and 5.5 cts., respectively.

"In this test it took approximately twice as much feed to maintain a cow when suckling a calf as it did during her pregnancy. . . .

"Corn plant fed in the form of silage is more palatable than if fed in the form of shock corn, which may be the cause of its being more efficient for the maintenance of beef-breeding cows.

"The yield of crops used in this test was 57.9 bushels of corn and 2 tons stover per acre; and for crops purchased, viz. clover hay and oat straw, yields of $1\frac{1}{2}$ and one ton, respectively, were assumed.

"On the above basis approximately one acre of land is sufficient to produce the crops necessary to support a breeding cow 140 days in winter, and this acreage should produce a considerable amount of grain in addition to that necessary for the maintenance of one cow.

"The product of one-third acre of land is sufficient to maintain a cow 140 days in winter, if we regard the surplus grain produced as offsetting an acreage proportionate to its market value."

Feeding experiments with cattle, E. R. LLOYD (*Mississippi Sta. Rpt. 1905, pp. 11-13*).—In a comparison of cotton-seed hulls with corn silage for beef production, it was found that 6 steers in 45 days made a total gain of 451 lbs. and consumed 240 lbs. of silage, 1,482 lbs. of hulls, 1,350 lbs. of hay, and 1,752 lbs. of cotton-seed meal and corn chops. A similar lot fed the silage ration gained 570 lbs. and ate 2,973 lbs. of silage, 240 lbs. of hulls, and the same quantities of the other feeding stuffs as the first-mentioned lot. "The results show 1 lb. of hulls equal to 1.58 lbs. of ensilage. This indicates ensilage to be the cheaper feed."

Some data are recorded regarding the cost of rearing and wintering cattle and regarding pasture gains. The estimated total cost of raising a "feeder" to the end of the third year was \$23.75, the average weight of the steer 930 lbs., and the calculated net profit \$13.45. The feed required to finish the steers cost on an average \$11.42 per steer, making the estimated net profit when the finished animals were sold, \$14.10.

The cost of growing and finishing young cattle was studied with 5 calves, which ran with their dams through the first winter without additional feed, then were pastured through the summer and wintered as yearlings on hay, and finished and sold the following winter when 28 months old. The cost of feeding to the beginning of the finishing period was \$12.99 per head and during the finishing period \$12 per head. Taking into account the cost of marketing, the net profit per steer was calculated to be \$17.26. During the 155 days of the fattening period the "best daily gain was 2 lbs.; the smallest daily gain was 1.65 lbs."

The estimated cost of wintering a breeding herd of 18 cows and a bull was \$84.10, or \$4.66 per cow. The cattle had access to a rick of hay, and from December 29 to April 1 were fed a little cotton-seed meal and hulls and as much shredded fodder as they would eat up clean. The above estimate includes the purchased feed hulls and cotton-seed meal, but does not take into account the home-grown hay.

As regards gain made on pasture, it was found that 3-year-old steers which had been wintered on hay without grain gained 209 lbs. per head on an average when pastured from April 1 to November 15. Yearling steers which had been fed during the winter on corn, cotton-seed meal and hulls made an average gain

of 45 lbs. per head on pasture, and young heifers which had been wintered on hay without grain gained, on an average, 191 lbs. on pasture.

For several years wheat has been included in the station's system of crop rotation for producing hay. It is cut in the dough stage and cured, the land being then plowed and planted to corn or to cowpeas. To determine the effect of grazing, on the yield of wheat hay, 8 calves were pastured on a plat of 3.75 acres for one month. They averaged 350 lbs. in weight "and made fair gains on the wheat without other food." The grazed wheat headed out and was ready to harvest 10 days later than a similar plat which had not been grazed, the yield of hay from the two plats being respectively 1,210 lbs. and 1,812 lbs. per acre.

Steer feeding, A. SMITH (*Mississippi Sta. Rpt. 1905, pp. 18, 19*).—A test was undertaken to compare stable feeding with feeding in an open yard and to study the relative merits of a mixed ration of hay, corn meal, wheat bran, cotton-seed meal and cotton-seed hulls with a ration of cotton-seed meal and hulls alone. Seven steers fed the mixed ration in the stable for 96 days made an average daily gain of 2.00 lbs. at a cost of 8.5 cts. per pound. Three steers fed a ration of the same character under the same conditions made an average daily gain of 1.35 lbs. per head at a cost of 10.7 cts. per pound.

A similar lot of 5 steers fed cotton-seed meal and hulls in the stable gained, on an average, 1.93 lbs. per head per day, the cost of a pound of gain being 6.1 cts. Five steers kept in an open lot but with access to shelter when fed the mixed ration made an average daily gain of 2.8 lbs. per head per day at a cost of 9.1 cts. while a similar lot fed meal and hulls in an open lot without shelter gained 1.52 lbs. per head per day at a cost of 8.2 cts. per pound.

The calculated net profit from the cattle used in the above tests was \$79.87.

"The results of the experiments serve to show that good cattle can be fed at a profit and that higher prices can be obtained for cotton-seed products, corn, and hay by feeding the same to a good type of beef cattle than by selling in a cash market and at the same time the fertilizer material may be retained on the farm to increase the productiveness of the soil."

Sheep, E. R. LLOYD (*Mississippi Sta. Rpt. 1905, p. 14*).—As shown by the recorded data for 4 years, the average cost of wintering sheep at the station has been \$1.14 per head. The estimated profits from a flock of 22 sheep for last year were \$42.36 and none of the breeding ewes were sold. "There is ready sale for early lambs at good prices. Sheep could easily be made one of the most profitable lines of live stock farming for the average farmer in this State."

Grazing hogs, E. R. LLOYD (*Mississippi Sta. Rpt. 1905, pp. 13, 14*).—Cowpeas without grain have so far given better results, it is stated, than any of the other crops tested at the station. In 1903 the cowpeas were grown on thin hill land and an acre produced 350 lbs. of pork. In 1904 the crop was grown on good valley land and produced 483 lbs. of pork per acre. The pigs were turned on the pasturage when the cowpeas were ripe and were fed no grain in addition to the pasturage.

Alfalfa without grain has been found "to be little more than a maintenance ration for hogs." The pigs used in the test, which covered 2 years, ranged from 3 to 24 months in age.

Ensilage for hogs; dipping for horses (*Natal Agr. Jour. and Min. Rec., 9 (1906), No. 5, pp. 485-488*).—Silage, presumably corn, has been found a satisfactory feed for horses at the Mooli River Remount Depot. The winter ration consisted of 4 lbs. of silage chopped with 2 lbs. of alfalfa or other forage, an ounce of salt, and a few pounds of crushed corn.

It is stated that dipping horses has been successfully practiced and is followed by freedom from ticks and skin diseases.

Farm poultry, with the results of some experiments in poultry houses and fattening chickens, W. R. GRAHAM (*Ontario Agr. Col. and Expt. Farm Bul. 151, pp. 40, figs. 25*).—The rearing, feeding, and management of chicks are discussed on the basis of station experience. The rearing of market fowls, housing poultry, the use of trap nests, construction of fattening crates, the use of the cramming machine, dressing and shipping poultry, egg preservation, and related topics are also spoken of and some experimental work is briefly summarized.

The effect of different housing conditions upon egg production is shown by the fact that during January, February, and March some 50 hens kept in a warm house laid 946 eggs, while a similar lot in a house with a cloth front laid 1,092 eggs. The hens in a cold house laid 1,021 eggs and those in a house with movable windows 1,035 eggs. During the same 3 months of the preceding year the hens in the warm house laid 607 eggs, those in the house with cloth front 718 eggs, in the house with movable windows 819 eggs, and in the cold house 1,074 eggs.

According to the author, "every hen should be allowed at least 6 sq. ft. of floor space. Each bird of the Plymouth Rock, Wyandotte, and such breeds, requires about 9 in. of perch room; Leghorns, etc., about 8 in.; and Brahmas 10 in. Roosts should be made low or near the ground. There are several reasons for this. Fowls of the heavier breed can not fly high, and those of the lighter breeds frequently injure the soles of their feet in jumping from high perches."

In the author's experience, "the best results are obtained from keeping 20 to 25 birds in a flock. Some succeed with 60 to 75 in a flock, but these are the minority."

As regards egg production of different breeds, it was found that 13 Plymouth Rock hens laid 693 eggs, the average cost per dozen being 6.02 cts., and during the same time an equal number of Andalusians laid 834 eggs, the cost per dozen being 5.34 cts.

In general, hens over 2 years old, the author points out, are seldom good layers. "Leghorns, Minorcas, etc., are sometimes good during their third and fourth years; but, generally speaking, the Rocks and such fowls are of little or no use as layers after the second year, being much inclined to become excessively fat.

"For summer egg production the lighter breeds of late-hatched pullets of the heavier breeds are best. Do not expect a hen that has laid well all winter to lay exceptionally well during the summer."

Wet and dry feeding and other similar topics are considered. As regards practice at the Ontario Agricultural College, it is stated that for the last year or two mashes have been little fed, such materials being very largely replaced by sprouted grain. "So far as we can see at the present time, the sprouting does not improve the feeding qualities of the grain very much, with the exception of oats. The palatability of oats is increased considerably. We have made the oats equally as palatable by soaking them in warm water about six hours. At the present time our plan of feeding is to feed whole grain in the litter in the morning, using about one to two pounds for twenty birds, the latter amount when they are laying heavy; at noon feed mangels, clover hay, and meat food in the winter time. If we have no meat, a small quantity of grain is scattered in the litter on the floor. In the summer time no grain or feed of any description is given. At night they are fed all the sprouted grains, either oats or barley, sometimes wheat, they will eat. During very cold weather in the winter they

are fed occasionally corn, either in the morning or evening. Where this is given, it is scattered in the litter."

As regards the merits of natural and artificial hatching, the author is of the opinion that as good results can be obtained with the incubator as with the hen.

In a test of the gains made by chickens fattened in July it was found that 12 Plymouth Rocks fed in a crate gained on an average 2.1 lbs. per head and required 3.2 lbs. of grain per pound of gain. Under similar conditions 8 high-grade Leghorns made a gain of 1.28 lbs. per bird, requiring 3.4 lbs. of grain per pound of gain. When dressed, they were somewhat plumper than the Plymouth Rocks, owing to their being mature, but they were rather small.

The author points out that the majority of buyers regard crate-fed birds as superior to those fed loose in pens. His own preference is for feeding in crates, as it takes less room, and he believes that the poultry can be thus fed with less labor and will produce a more even product. "No matter which method is followed, cockerels should be fed for 2 weeks or more before they are killed and sold."

Tests of the relative value of different grain rations extending over a number of years are summarized. In general, the smallest and most expensive gain was made on a mixture of corn meal and pearl oat dust 2:1, and the largest and cheapest gain on corn meal, ground buckwheat, and pearl oat dust 2:2:1. Skim milk was fed in addition to the grain in all cases.

Data are recorded which show the exact quantities fed to fattening birds, the general principle of such feeding being light rations at the beginning with a gradual increase until all the feed is given which will be eaten up clean. No feed is left before the birds longer than 10 minutes after it is placed in the trough. Some data are also given regarding the relative gains made by individual birds in 3 weeks.

From a summary of data on the relative value of whey, skim milk, and numerous feeds for fattening chickens, it appears that gain was most cheaply made on a mixture of equal parts of corn meal, oatmeal, and shorts mixed with whey, the cost being 4 cts. per pound, and was most expensive (6 cts. per pound) on a mixture of equal parts of corn meal, shorts, and oatmeal, with 30 per cent of pork scrap, water being used to wet up the ration.

"Sour skim milk, i. e., milk that is thickened, is, without doubt, the best liquid to mix with grain rations where a uniform product is wanted, and more so where white-fleshed chickens are in demand.

"Sweet skim milk has not a feeding value for grown chickens equal to sour milk.

"Whey is a better food than is generally considered. The results appear to indicate that it aids digestion.

"Whey and pork scraps have not given the results expected.

"Where pork scrap and beef scrap can be procured at reasonable cost, say 2 cents or less per pound, they are good value, especially where a yellowish flesh is in demand.

"Grain mixtures only, mixed with water, are not economical, considering this test."

Poultry experiments, G. M. GOWELL (*Maine Sta. Bul.* 130, pp. 101-132, pls. 5).—Additions to the station poultry plant are described, as well as a recently established poultry farm; methods for the selection of breeding stock are outlined; detailed accounts are given of methods of feeding chickens and hens followed at the station, and experiments are reported.

In a test to determine the effects of early maturity on laying, it was found that a lot of chickens selected in July and August because they were evidently about to begin laying, gave an average of 180 eggs per bird in a year, as com-

pared with 144 eggs per bird from all the station pullets. The large number of eggs laid by the selected early pullets, and the fact that few of them were poor layers, in the author's opinion, shows the advantage of selecting early layers for breeding purposes.

As regards the feed required for raising broilers the station records show that cockerels hatched in April and May, when 11 or 12 weeks old, weighed 2.25 lbs. dressed, and pullets 1.75 lbs. On an average both pullets and cockerels had eaten 9 lbs. of grain, 1 lb. of beef scrap, and 0.25 lb. of grit. The estimated cost of feed required to raise a 2-lb. broiler was 23 cts. "To make broiler raising most profitable, warmed houses should be used and the birds raised early enough to be all marketed while high prices are obtainable."

The dry-feed system of feeding referred to in earlier publications (E. S. R., 17, p. 388) is discussed and data recorded regarding the amounts eaten per hen during the past year, which were grain and meal mixture 90 lbs., oyster shell 4 lbs., dry cracked bone 2.4 lbs., grit 2 lbs., charcoal 2.4 lbs., and clover 10 lbs.

Succulent feeds are supplied to the station poultry throughout the year. In a test beginning January 1 and covering 4 months mangel-wurzels and cut clover were compared with 2 lots of 100 hens each. The lots were fed and cared for alike, except that one received 17 lbs. of mangels per day and the other 5 lbs. of clover leaves and heads. On mangels the average egg yield was 63.9 eggs per hen and on clover 59.6 eggs.

"The slight difference between the yields of the two lots can hardly be regarded as indicating greater value for the mangold ration.

"The vigor and apparent healthfulness of the two lots were equally good. In the general feeding both mangolds and clover are used daily. Formerly it was thought necessary to steam or wet the clover with hot water, in order to get good results from it. It is now cut and fed dry, in the bottom of cement barrels, cut off about ten inches high. About 5 pounds are eaten daily, by 100 hens, with very little waste. Apparently as good results are gotten from it as when it was scalded, the labor of preparation being very much lessened."

Using 50 year-old Barred Plymouth Rock hens, which had been kept by themselves since they were 12 weeks old, the time required to establish fertility in eggs when hens are first mated was studied. All the eggs laid the first day of mating were found to be infertile. Eggs laid the second day showed fertility in different degrees. From 21 eggs laid the third day 10 chicks were hatched. "The eggs laid during the days immediately following the fourth day of mating yielded rather more than 50 per cent of good chicks, which is about the percentage usual in the general incubation work here, which, however, is done earlier in the season, when conditions are supposed to be not as favorable."

It is commonly believed that eggs from hens which have been laying for a long time are less likely to hatch than those produced earlier in the laying period. To test this point, eggs laid the first 10 days of each month from January to October by 40 hens were incubated. The percentage which hatched ranged from 24 in February to 61 in April. The percentage was also noticeably high (52 to 58 per cent) in July, August, and September. "From this test there appears no support of the theory that long-continued laying reduces the chick-producing capacities of the eggs."

The effects of long and short mating periods upon the proportion of eggs which hatched were also studied. From pens where the males and females ran together all winter 3,240 eggs were incubated and 1,529 chicks were hatched, an average of about 1 chick to 2.13 eggs. From pens where the males and females had not been together until the mating season began 2,160 eggs were incubated and 1,075 chicks hatched, or about 1 chick to 2 eggs.

"These slight differences in results should not be interpreted as meaning that there are advantages in the short over the long matings. . . .

"While the results of this test may not be convincing, the 1,500 birds employed and the large number of eggs incubated, with the satisfactory average yields of a chick from 2 eggs, does furnish data sufficient to remove scruples regarding the fitness of long-mated birds for breeders."

Poultry investigations at the Maine Agricultural Experiment Station, C. D. Woods and G. M. GOWELL (*U. S. Dept. Agr., Bur. Anim. Indus. Bul. 90, pp. 42, pls. 5, figs. 2*).—This is a revision of a bulletin of the Maine Station (E. S. R., 15, p. 1104). The new material which has been incorporated consists very largely of descriptions of the station poultry plant, the methods followed in poultry experiments, and the way in which data are recorded.

Poultry division, F. B. LINFELD (*Montana Sta. Rpt. 1905, pp. 253, 254, figs. 2*).—A brief account of the station poultry and the eggs laid. Hens kept in a small and inexpensive colony house with a drop curtain front and having quite a free range made the best record, producing on an average 165 eggs per bird per year. A new poultry building at the station is described.

Preserving eggs, R. W. THATCHER (*Washington Sta. Bul. 71, pp. 14*).—The relative value for preserving eggs of 10 per cent and 5 per cent solutions of water glass, of a mixture of limewater and salt brine (the limewater being made by mixing a pound of quicklime and 0.5 lb. of table salt with 4 qts. of boiling water), and of a commercial egg preservative were studied. The eggs were placed in stone jars, 50 to a jar, and the liquids poured over them until they were entirely submerged. The eggs were examined at intervals for 8 months.

"These experiments show that eggs can be kept in good condition for home use at least eight months by immersing them either in a water-glass solution or in limewater and salt brine. Those preserved in water glass this year appeared to come out in better condition than those kept in the lime and salt mixture. Other experimenters have succeeded in keeping eggs to their entire satisfaction in solutions of water glass as dilute as 5 per cent, but the author's experience this year was that a stronger solution gave a better preservation. It seems probable that a solution halfway between the two which were used . . . would be better than either of these, since it would doubtless give a better product than the weaker solution and would not deposit sediment, thereby gradually losing strength, as the stronger solution did."

The author calculates that a pound of water glass properly diluted is sufficient to cover 12 to 15 doz. eggs and that the cost of the preservative would be less than one cent per dozen.

"Each day's gathering of eggs may be packed immediately after gathering by placing them in the jar and pouring over them just enough of the solution to cover them. This is better than to hold the eggs for several days, at the risk of their becoming stale, in order to have a sufficient number to fill the entire vessel at one time.

"Eggs packed by . . . [the water glass] method will keep for some time after they are removed from the preservative solution. The author has used some which have been out of the solution for four weeks without being able to detect any deterioration in quality."

DAIRY FARMING—DAIRYING—AGROTECHNY.

Modern dairy farming, H. L. PUXLEY (*London: L. V. Gill; New York: C. Scribner's Sons, 1906, pp. 238, pls. 8, figs. 32*).—This is designed to be a practical handbook for the beginner in dairy farming. It deals not only with such matters as the selection and management of cows, the milk supply, butter

making, and cheese making, but also with the production of various field crops, veterinary remedies, and pig feeding.

The book embodies the results of considerable practical experience and for this reason will doubtless be found very useful, but unfortunately for an elementary treatise it is not entirely free from mere theories or loose statements. For instance the author considers it possible that "in good germs the valuable and health-giving properties of milk reside." And again, "the spores of most bacilli are as easy to destroy as the bacilli themselves."

Report of the dairy commissioner for the Dominion of Canada, 1906 (*Rpt. Dairy Comr. Canada, 1906, pp. 157, pls. 24*).—This report on the progress of the dairy industry in Canada contains considerable statistical matter, results of experiments in the cool curing of cheese, notes on the management of cheese-curing rooms, directions for coating cheese with paraffin, classifications and standards for butter and cheese, plans for cheese factories and creameries, a reprint of a bulletin on creamery cold storage, an account of a visit to Europe in the interests of Canadian dairying, and other articles of a like nature.

Annual report of the association for the development of the dairy industry of Hoorn, 1905 (*Verslag Ver. Exploit. Proefzuivelboerderij Hoorn, 1905, pp. 35*).—This report includes notes and observations on the use of pure cultures in dairying, milk with abnormal properties, ripening of Edam cheese, hay extract, etc.

Report of the experiment station and dairy institute at Kleinhof-Tapiau, 1905-6, HITCHER (*Ber. Vers. Stat. u. Lehranst. Molke. Kleinhof-Tapiau, 1905-6, pp. 12*).—An account is given of the work of this institute during the year including data on the production of the dairy herd at the institute and of other herds in that region.

Dairy department, W. J. ELLIOTT (*Montana Sta. Rpt. 1905, pp. 285-288*).—In this report are given the amount and cost of feed and the returns from milk and butter for each of the 15 cows in the station herd during the year. The average profit per cow over cost of feed was \$49.20.

Report of dairy department, A. SMITH (*Mississippi Sta. Rpt. 1905, pp. 20-22*).—This report includes a monthly record of 15 cows for 1 year, a brief statement concerning experiments in sheltering cows, and making cheese. The results of a brief trial indicated that exposure to stormy weather caused a shrinkage in the yield of milk. The work with cheese, according to the author, shows that good cheese can be produced in the State.

Preliminary observations on protein supply of dairy herd, T. I. MAIRS (*Pennsylvania Sta. Rpt. 1905, pp. 96-104*).—During 1905 the station herd of 34 cows was divided into two lots, one of which was fed more protein than the other. Records are given of the individual cows for January to May, 1905, and for comparison for the year 1904. The results so far obtained are not considered as warranting any definite conclusions.

Testing cows for advanced registry, C. L. BEACH (*Connecticut Storrs, Sta. Rpt. 1905, pp. 24-32, figs. 3*).—This gives the results of official tests of 6 cows for advanced registration and also milk and butter fat records for 1 year of individual cows in 5 dairy herds. The production of butter fat by individuals ranged from 135 lbs. to 421 lbs., and by herds from 190 to 319 lbs.

On the influence of grooming cows and adding certain mineral substances to feeds upon the yield and quality of the milk, LIPSCHITZ (*Nederland. Weekbl. Zuivelbered. Veentecht, 12 (1906), No. 11; abs. in Milchev. Zentbl., 2 (1906), No. 10, p. 462*).—The thorough cleaning of cows did not result in an increased yield of milk, as was found in Russian experiments (E. S. R., 17, p. 72). The feeding of 50 gm. of salt per cow daily was found to be excessive. The digestion of the animals was unfavorably influenced and

the ash content of the milk was increased. An allowance of 15 to 30 gm. is recommended. The feeding of 50 gm. of calcium phosphate in the form of bone meal decreased rather than increased the yield of milk. The ash content of the milk was increased.

Some experiment station work relating to the production and sale of pure milk, H. W. LAWSON (*U. S. Dept. Agr., Office Expt. Stas. Rpt., 1905, pp. 281-301*).—A review of station publications relating to sanitary milk production.

Inspection of dairies, C. HARRINGTON (*Ann. Rpt. Bd. Health Mass., 37 (1905), pp. 519-526*).—This is a report on the inspection of 2,151 dairies in Massachusetts during the 7 months ended September 30, 1905. Of the whole number of dairies inspected 1,720 were found to possess one or more objectionable features. The nature of these defects is briefly set forth.

Studies of market milk, W. A. STOCKING, JR. (*Connecticut Storrs Sta. Rpt., 1905, pp. 16½-21¼*).—The author has been studying for 2 years the sanitary condition of milk as produced and delivered by individual dairymen. In this paper are given the detailed results of numerous examinations of milk as delivered by 30 producers from September to March to a shipping station to be sent to Providence, Rhode Island.

The composition of the milk was found to be satisfactory. In other respects, the milk was considered very poor. "In fact it was found to be impossible to keep most of this milk sweet long enough to get it to the city even when placed in cars and iced as soon as received." In general the dirt content increased with the number of bacteria present. The milk examined was considered by the author as representing about the poorest quality produced in Connecticut.

Milk hygiene investigations, W. RULLMANN and R. TROMMSDORFF (*Arch. Hyg., 59 (1906), No. 3, pp. 224-265*).—This is a detailed account of investigations on the presence and significance of leucocytes and streptococci in milk. Brief reference has already been made to other articles by these authors in which the substance of the work was reported (*E. S. R., 17, pp. 1007, 1008*).

Milk contamination in collection and transit, J. S. LLOYD (*Vet. Rec., 19 (1906), No. 941, pp. 41-44*).—This is an abstract of an address in which were discussed methods of examining milk for impurities and the sources, effects, and means of prevention of its contamination.

Fecal material and bacteria in milk, J. WEBER (*Chem. Ztg., 30 (1906), No. 84, pp. 1035, 1036*).—In an address the author stated that only 10 per cent of cow manure added to milk can be recovered as dry insoluble matter. Means of securing milk with a minimum amount of bacterial and other contaminations were discussed.

Destruction of tubercle bacilli in the manufacture of milk powder by the Just-Hatmaker method, W. HOFFMANN (*Arch. Hyg., 59 (1906), No. 3, pp. 216-223, fig. 1*).—The results of inoculation experiments with guinea pigs showed that bovine tubercle bacilli are destroyed in the manufacture of milk powder by the Just-Hatmaker process.

A contribution to the question of feeding young animals raw v. boiled milk, R. EICHLÖFF (*Milchz. Zentbl., 2 (1906), No. 10, pp. 458-462*).—A comparative study was made of the bones and blood of 8 puppies, 4 of which were fed raw milk and 4 milk which had been boiled for 15 minutes. While the results of the experiments were not considered very conclusive they seemed to indicate certain abnormal changes in the tissues of the puppies fed boiled milk.

An effort was made to determine if injurious substances are developed in the process of heating. Milk heated for 150 minutes over a naked flame showed the presence of 0.0126 per cent of ammonia. The same process resulted

also in the production of 0.000204 gm. of sulphuric acid in 100 cc. of milk. Phosphorus was also detected in the distillate from heated milk, but whether in the free form or as phosphoric acid was not ascertained.

On the phosphorus and calcium of human milk, A. W. SIKES (*Jour. Physiol.*, 34 (1906), No. 6, pp. 464-480, figs. 5).—The author analyzed 79 samples, finding P_2O_5 during the first 14 days after the commencement of lactation to vary from 0.0140 to 0.0522 per cent and to average 0.0297 per cent, and the calcium to average 0.0301 per cent. The nonproteid phosphoric acid averaged 0.0169 per cent and the proteid phosphoric acid 0.0124 per cent. The ratio of the proteid phosphoric acid to the total phosphoric acid averaged 42.3. Assuming that the proteid in human milk averages 2 per cent, the phosphoric acid in this would be 0.62 per cent. The calcium combined with the proteid bore a ratio to the total calcium of 84:100. Calcium averaged 1.06 per cent of the total proteid.

Infantile mortality and goats' milk, W. WRIGHT (*Lancet [London]*, 1906, 11, No. 18, pp. 1212, 1213).—Among the reasons offered in this effort to show that goats' milk is superior to cows' milk for infant feeding are the greater ease with which goats' milk is digested, the natural cleanliness of the animals, and their practical immunity toward tuberculosis.

Feeding experiments with perhydrase milk, A. BÖHME (*Deut. Med. Wchenschr.*, 32 (1906), No. 43, pp. 1729-1733).—The results of a number of tests indicated that milk treated with hydrogen peroxid according to the method of Much and Römer is suitable for feeding infants over 3 months of age. The superiority of the perhydrase milk over boiled milk was indicated by a greater increase in weight and the rapid disappearance of rachitic symptoms.

Some bacteriological dairy investigations, II. WEIGMANN, T. GRUBER, and H. HUSS (*Milchw. Zeitbl.*, 2 (1906), No. 10, pp. 441-451, pls. 2).—Bacteriological investigations were made of several faulty cheeses, a sample of abnormal cream, and bitter milk. The organisms considered responsible for the troubles were isolated from the different samples. A brown coloration in the interior of 2 types of cheese was attributed to the effect of *Bacterium casci fuscii*, the growth of which is illustrated in plates.

The application of mechanical refrigeration to ice cream manufacture, J. H. HART (*Jour. Franklin Inst.*, 162 (1906), No. 5, pp. 397-403).—A description of the methods employed in the manufacture of ice cream.

Report of the jury on the examination of pasteurizing apparatus at the third international dairy exposition at Brussels, 1904 (*Rapport du jury chargé d'examiner les appareils de pasteurisation ayant participé au concours organisé à l'occasion de la 3me Exposition Internationale de Laiterie à Bruxelles, Avril 1904. Brussels: E. Dacm, 1906, pp. 70, figs. 29*).—This gives the results of tests of 11 pasteurizers.

Our butter analysis (*Country Life [London]*, 20 (1906), No. 515, pp. 689, 690).—The editor of *Country Life* secured 1 sample each of what was believed to be the best Danish, the best Italian, the best Brittany, and the best English butter procurable in London, marked the samples respectively A, B, C, and D, and submitted them to F. J. Lloyd for examination. The analyses are as follows:

Analyses of butter.

Source.	Water.	Fat.	Casein.	Salts.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Danish.....	12.55	84.91	0.71	1.83
Italian.....	14.64	82.97	1.39	1.00
Brittany.....	13.64	84.88	.86	.62
English.....	11.99	87.03	.72	.26

The results of examinations made when the samples were first obtained and after 16 days, including the bacteriological data, were considered decidedly in favor of the English butter. Notwithstanding the low percentage of salt, this showed superior keeping qualities and was pronounced the cleanest and best sample.

Annual report of the experiment station for cheese making at Lodi, 1905, C. BESANA ET AL. (*Ann. R. Staz. Sper. Caseif. Lodi, 1905, pp. 127*).—This contains a review of the work of the station during the year, a report of experiments in feeding skim milk to pigs, investigations on the ripening of cheese, analyses of rice products, a study of the potable waters of Lodi, and other articles.

In the investigations on cheese ripening by G. Cornalba, chemical analyses were made of Grana and Provoloni cheese. The results showed that in Grana cheese, ripening proceeds from the center outwards. In the ripened cheese only a small quantity of the casein is in a soluble form. The quantity of ammonia which is formed from the soluble casein, however, is considerable and this represents a considerable portion of the soluble nitrogen. The volatile acids are represented principally by caproic, acetic, and butyric acids, the latter predominating. The fat does not undergo appreciable changes. The volatile fatty acids are not saponified by the ammonia. In Provoloni cheese as in Grana considerable ammonia is formed from the soluble casein. In the ripened cheese two volatile acids are present—caproic and butyric. The process of ripening is also centrifugal.

On the influence of the addition of different substances to cows' milk upon the coagulation of the milk with rennet, C. SMELIANSKY (*Arch. Hyg., 59 (1906), No. 3, pp. 187-215*).—The literature of this subject is reviewed and experimental work reported.

Either the time required for coagulation or the character of the coagulum was affected by pasteurization, dilution of the milk with water, the addition of mucilaginous substances obtained from grains, and the addition of various salts, including sodium carbonate, sodium chlorid, potassium carbonate, and calcium chlorid. The different kinds of sugars tested, on the contrary, were without influence.

The action of rennet on casein, E. PETRY (*Beitr. Chem. Physiol. u. Path., 8 (1906), No. 8-10, pp. 339-364*).—The author discusses briefly some of the literature of this subject and reports studies of the chemical properties of the cleavage products resulting from the action of rennet, the conditions of rennet action, the effect of rennet upon various proteids, and the relation of milk coagulation to the proteolytic action of the rennet ferment. Two distinct actions of rennet are recognized, one resulting in the formation of paracasein, and the other proteolytic.

Nature and conditions of rennet action, K. SPIRO (*Beitr. Chem. Physiol. u. Path., 8 (1906), No. 8-10, pp. 365-369*).—The author discusses the digestive action of rennet upon casein solutions.

The national fruit and cider institute (*Nat. Fruit and Cider Inst., Long Ashton [Eng.], Rpt. 1906, pp. 32*).—In order to determine whether apples are sufficiently ripe for cider making it is suggested by F. J. Lloyd that a test be made for starch, which is absent in mature apples.

B. T. P. Barker reports analyses of ciders made from different varieties of apples and discusses the characters of the fruit which are most valuable for cider making. The factors considered of primary importance are the characteristic flavor of the variety and the rate of fermentation of the juice. Other characters which are of minor importance only are the chemical composition of the fruit, the yield of juice, the characters of growth, such as the abundance

and yield of fruit, and the season of flowering and ripening. Extensive tests have been made of numerous varieties of apples for cider making. The results indicate that a particular variety yields the same type of cider regardless of the source of the apples. Very few varieties are believed to possess all the characteristics necessary for the production of first-class cider. Experiments in blending were also conducted.

On the cause of the production of aldehydes in wine and the quantity which is present in certain wines of Tuscany, N. PASSERINI (*Staz. Sper. Agr. Ital.*, 39 (1906), No. 3, pp. 221-240).—Aldehydes are considered a normal product of alcoholic fermentation. They are produced by aerobic ferments rather than anaerobic. The amount of aldehydes in wine is increased by the treatment of the must with sulphites. The presence of oxydase derived from *Botrytis cinerea* is not believed to be a cause of the formation of aldehydes.

In the wines of Tuscany the aldehyde content varied from 1 to 60 mg. per liter. Wines with a high alcoholic content contained usually the largest amount of aldehydes and white wines contained more than the red.

On the influence of temperature on the odor and taste of wine, J. WORMANN (*Landw. Jahrb.*, 35 (1906), No. 5, pp. 741-836).—The temperature of wine is considered of considerable importance in judging, inasmuch as it has an influence upon the odor and taste of the wine. Numerous experiments were conducted for the purpose of determining the most favorable temperature for testing a considerable number of wines.

Clarification of sugar with iron compounds, H. C. P. GEERLIGS (*Meded. Proefstat. Suikerriet West-Java, 1906, No. 92, pp. 8*).

The inorganic constituents of cane juice in their relation to the sugar content of the juice, H. C. P. GEERLIGS (*Meded. Proefstat. Suikerriet West-Java, 1906, No. 93, pp. 33*).

Modern soaps, candles, and glycerin, L. L. LAMBORN (*New York: D. Van Nostrand Co.; London: Crosby, Lockwood & Son, 1906, pp. XX + 688, figs. 225*).—This is "a practical manual of modern methods of utilization of fat and oils in the manufacture of soap and candles, and of the recovery of glycerin."

VETERINARY MEDICINE.

Annual report on investigations in the field of veterinary medicine, ELLENBERGER ET AL. (*Jahresber. Vet. Med.*, 25 (1905), pp. IV + 436).—As in previous summaries of this series the authors have brought together abstracts of all veterinary literature of the year available to them. The literature is classified as usual according to the nature of the articles and the volume is provided with a complete name and subject index.

Annual report of veterinary department of station, J. C. ROBERT (*Mississippi Sta. Rpt. 1905, pp. 25, 26*).—A brief account is given of the work of the station on Texas fever, blackleg, anthrax, glanders, milk fever, and peavine disease.

Some complaints had been received that peavines occasionally poison or cause the death of cows. An examination of cow peas failed to show the presence of any poisonous substance.

Second report of the Wellcome research laboratories at the Gordon Memorial College, Khartoum, A. BALFOUR (*Khartoum: Dept. Ed., Sudan Govt., 1906, pp. 255, pls. 21, figs. 106*).—The larger part of this report is occupied with accounts of recent researches in the Wellcome laboratories on mosquitoes, tsetse flies, and other biting insects, various insect pests injurious to cultivated crops, and on trypanosomiasis and other diseases of man and animals in the Anglo-Egyptian Sudan.

In view of the proposed extension of irrigation work in the neighborhood of Khartoum the author advises that a dry belt 1 mile in width be preserved around the city in order to prevent the infestation of the city with mosquitoes. Notes are given on methods of destroying mosquitoes in pools, swamps, houses, and ships. The different species of tsetse flies are described with particular reference to their agency in transmitting blood parasites. An account is also presented of plant lice on sorghum and other plants and of locusts, species of *Simulium*, horse flies, and other injurious insects.

Hamogregarina balfouri is reported as occurring in the jerboa and other mammals. A report is also made on the prevalence of trypanosomiasis in cattle, mules, and human beings and on blood examination and related subjects.

The report of the chemical laboratory (pp. 205-244) is noted elsewhere in this issue.

Tuberculosis of the food-producing animals, D. E. SALMON (*U. S. Dept. Agr., Bur. Anim. Indus. Bul. 38, pp. 99, pls. 9*).—The author has presented a discussion of the chief problems relating to tuberculosis. Statistics are given on the prevalence of tuberculosis in the United States and Europe and the extent of losses from this disease. The cause and pathology of tuberculosis are considered in detail and notes are given on the tuberculin test.

Particular attention is devoted to a consideration of the intertransmission of tuberculosis between man and animals and recent experiments in immunization of cattle to the disease. The author concludes that bovine tuberculosis may be communicated to human beings, particularly children, and that man may also become infected from tuberculous hogs, sheep, goats, and other animals but not from poultry. It is believed that human tuberculosis is transmissible to animals only in a relatively small percentage of cases.

With reference to the immunization of cattle to tuberculosis, the author calls attention to the fact that great progress has been made along this line, but that the results are not as uniform as could be desired. The methods now in use, however, are capable of great improvement.

The State may aid materially in the eradication of tuberculosis by requiring a tuberculin test, inspection of all slaughtered animals, and the payment of a reasonable compensation. Some help may also be derived from the establishment of breeding herds known to be free from the disease and maintained in healthy surroundings.

The living sources of tuberculosis, CADÉAC (*Jour. Méd. Vét. et Zootech., 57 (1906), July, pp. 397-399*).—While many means are known by which tuberculosis may be transmitted from one animal to another, it is impossible under ordinary circumstances to transmit the disease to any serious extent without a close association of affected and healthy animals. Such close contact makes it possible for contagion to be spread through either the respiratory or digestive organs.

Notes are given on the usual course of tuberculosis in cattle, goats, dogs, rabbits, sheep, and birds, with special reference to the stage of the disease when it is most infectious.

The avenues of infection with tuberculosis and the means of defense on the part of the organism, A. CALMETTE (*Rev. Sci. [Paris], 5, ser., 6 (1906), No. 9, pp. 257-265*).—The controversy concerning the usual mode of infection with tuberculosis is critically considered.

In the author's opinion, the most frequent source of infection is through the alimentary tract, especially the intestines. Tubercle bacilli introduced into the alimentary tract may penetrate through the walls of the intestines without leaving any lesion, and after they reach the lymphatic vessels they may be sur-

rounded by leucocytes and carried by these corpuscles into various parts of the body. The author believes that nearly all internal localizations of tuberculous infection are of intestinal origin.

Resorption of dead tubercle bacilli, A. MARMOREK (*Berlin. Klin. Wchnschr.*, 43 (1906), No. 36, pp. 1179, 1180).—Different samples of cultures were subjected to temperatures ranging from 100 to 120° C. for periods of 1 to 60 minutes, and experiments carried out on guinea pigs and rabbits with relatively large quantities of dead tubercle bacilli showed conclusively that these bacilli may be absorbed by the experimental animals without the production of an abscess at the point of inoculation.

In order to secure a resorption of the dead tubercle bacilli without the formation of an abscess it is necessary to carefully pulverize the material before making an injection, as if relatively large masses of dead tubercle cultures are deposited under the skin in experimental animals an abscess is sure to follow.

In general it is found that rabbits possess a much more striking power of absorbing the bodies of tubercle bacilli than guinea pigs, and therefore will endure a large quantity of tubercle bacilli without showing the development of extensive inflammation or abscesses.

The action of bovine and human tubercle bacilli upon anthropoid apes, E. VON DUNGERN and H. SCHMIDT (*Arch. K. Gesundheitsamt.*, 23 (1906), No. 2, pp. 570-587).—A series of inoculation experiments was carried out upon anthropoid apes, during which tubercle bacilli of human and bovine origin were used.

It appeared that the bovine bacilli were fully as virulent for the gibbon as human tubercle bacilli. Since the gibbon is considered as very closely related to man, it is argued that the results obtained may be looked upon as applicable also to man. Further experiments will be made along this line. When human tubercle bacilli were fed to gibbons, tuberculous foci appeared in the lungs, while after feeding bovine bacilli the alimentary tract and mesenteric glands were chiefly affected.

Protective vaccination against Texas fever, GRAFFUNDER (*Berlin. Tierärztl. Wchnschr.*, 1906, No. 36, pp. 656-659).—As a result of the study of this disease in Germany, the author concludes that a complete immunity can not be produced by 1 or 2 vaccinations.

It is recommended that the vaccination be done on calves from 6 weeks to 1 year old and preferably during the winter. The size of the vaccine dose varies from 5 to 15 cc.

Piroplasma bigeminum in Texas fever in Lolland, A. F. FOLGER (*Maanedsskr. Dyrlæger*, 18 (1906), No. 5, pp. 230-235, fig. 1).—Historical references are made to the literature of this subject with particular reference to the biology of the blood parasite and the use of hemoglobin in treating the disease.

Redwater in cattle, G. H. WOOLDRIDGE (*Agr. Students' Gaz.*, n. ser., 13 (1906), No. 1, pp. 2-12, pls. 3).—The author describes in some detail the symptoms and post-mortem appearances which may be observed in acute and chronic cases of Texas fever. The means of transmission as well as curative and preventive treatments are also discussed.

The cattle tick in its relation to southern agriculture, A. MAYER (*U. S. Dept. Agr. Farmers' Bul.* 261, pp. 22).—In the author's opinion the chief difficulty in the way of improving the cattle industry of the South is the presence of the cattle tick. It is recognized that the cattle tick on the range country is by no means so serious as on improved pastures in which the infestation has become continually worse.

Attention is called to the injury to cattle from parasitism with ticks. Aside from the agency of these pests in transmitting Texas fever, beef cattle badly

infested with ticks do not reach the size which they otherwise would attain. Milch cows sometimes abort as the result of excessive infestation or occasionally do not breed until 3 or 4 years old.

From a practical standpoint, the author finds some objection to the method of feed-lot rotation, but believes that the method of starving out the ticks is practicable and promises results.

Rinderpest in South Africa, G. TURNER (*Jour. Trop. Vet. Sci.*, 1 (1906), No. 3, pp. 269-283).—A brief account is presented of different methods which have been used in immunizing cattle against rinderpest.

Some of these methods suffer from the disadvantage that the immunity produced is of very short duration. In order to bring about a longer immunity, the author used serum from animals which have been repeatedly hyperimmunized. Reports have been received regarding the use of this serum on 108,000 cattle, in which the loss amounted to 1.3 per cent.

The importance of forage in the distribution of anthrax, P. SPISSE (*Stat. Sper. Agr. Ital.*, 39 (1906), No. 3, pp. 213-220).—In preventing the distribution of anthrax it becomes necessary to study carefully all possible means for the diffusion of this disease. According to the author's experiments, it is impossible for plants which grow in the soil over the buried carcasses of animals dying of anthrax to carry the contagion. Forage, however, which in any way becomes contaminated may serve as a means of transmitting the disease, especially in the presence of a lesion in the digestive tract.

Inoculation experiments with *Actinomyces asteroides* in guinea pigs, H. NAKAYAMA (*Arch. Hyg.*, 58 (1906), No. 3, pp. 297-312, pls. 4).—The literature relating to the biology and forms of actinomyces is critically discussed in connection with numerous bibliographical references.

The author undertook an elaborate series of experiments for the purpose of studying the biological forms under which actinomyces occurs, and also the effect of actinomyces on guinea pigs with particular reference to the problem of supersensitiveness. In the course of the experiments it was found that guinea pigs will endure a single inoculation with enormous quantities of actinomyces. In fact, the organism appears not to be able to cause death with acute symptoms of infection from the first inoculation. About 1 week after the first inoculation, however, a condition of excessive susceptibility to the disease is noted, and any further inoculation at this time results in the very rapid spread of the infection, and death. This stage of supersensitiveness persists for only 3 weeks, after which the animal returns to a normal condition, provided no second inoculation is given during the period.

The author believes that the condition of supersensitiveness observed in his experiments is sometimes present in the case of infection with tuberculosis, and may be held to account for the failure of immunization experiments in such cases.

Septic pneumonia of calves, RÜHM (*Wehnschr. Tierheilk. u. Viehzucht*, 50 (1906), No. 36, pp. 702-705).—The author observed 15 calves so badly affected with septic pneumonia that at the age of 3 months they were no larger than they should have been at 1 month. The 15 calves were given the serum treatment, and all recovered entirely. In addition a young calf, not affected, was vaccinated and appeared to be rendered immune to the disease.

Notes are given on the symptoms and pathology of the disease.

Infectious catarrhal bronchitis and pneumonia in cattle, MARTENS (*Berlin. Tierärztl. Wehnschr.*, 1906, No. 36, pp. 655, 656).—Cattle are not commonly supposed to be affected with an infectious pneumonia similar to that which prevails in the horse. The author, however, observed a number of cases and made a study of the symptoms and course of the disease.

The symptoms were very similar to those of pneumonia in the horse, including fever and a catarrhal discharge. The mild cases ran a course of 6 to 8 days, while in more serious cases the disease persisted for 4 to 6 weeks. A favorable outcome took place in all cases, but 1 animal was slaughtered for further observation. In this case there was a pronounced hepatization of the lungs, and the bronchi were filled with a catarrhal secretion.

The symptoms in general might cause a supposition of pleuro-pneumonia, but the incubation period was not longer than 8 days, while in pleuro-pneumonia it is ordinarily several weeks.

The treatment of infectious vaginal catarrh of cattle by means of salves, SCHWEIKERT (*Berlin. Tierärztl. Wchnschr.*, 1906, No. 35, pp. 639, 640, fig. 1).—The method of treating this disease, previously recommended by the author, consists in the local application of antiseptic salves by means of a syringe especially designed for this purpose. A number of veterinarians suggested the desirability of having a syringe constructed in such a way as to be separable into two parts for greater convenience of carrying. This has been done, and the apparatus promises to be more convenient than a solid syringe.

Epizootics of cowpox among dairy cows, FRÉGER (*Jour. Méd. Vét. et Zootech.*, 57 (1906), July, pp. 385-392, fig. 1).—While cowpox is a benign disease and does not lead to serious results with the cows, it may nevertheless cause great annoyance in outbreaks of unusual extent. A number of such outbreaks are described by the author.

It was found that if the ordinary vaccine obtained from pustules on the udder was used in vaccinating cows in the region of the perineum the pustules rapidly disappeared on the udder and the cows became noninfectious. The author believes, therefore, that the distribution of the disease may be rapidly checked by adopting this method of treatment.

Warble flies and their control by law, R. OSTERTAG (*Ztschr. Fleisch u. Milchhyg.*, 16 (1906), No. 12, pp. 407-413).—The life history of *Hypoderma bovis* is described in considerable detail and notes are given on the injury caused by this pest to cattle hides. It is estimated that this insect causes in Germany a loss of 6,000,000 to 8,000,000 marks.

Tanners have suggested the desirability of a law compelling stock raisers to remove and destroy all larvæ of warble flies found in the skin of cattle. In a few instances where this has been tried, particularly in Ireland, good results have been observed.

Trephining the skull for *Cœnurus cerebralis bovis*, F. BRAUN (*Wchnschr. Tierheilk. u. Viehzucht*, 50 (1906), No. 24, pp. 461-463).—Some unsatisfactory experiences in operating to remove this parasitic worm are related by the author.

In one case the animal showed violent cerebral symptoms after an apparently successful removal of the parasite and had to be killed. The author, therefore, recommends against such operations since the parasite is usually located deep in the tissue of the brain and since frequently there may be several cysts in the same brain.

A disease of sheep in Ayrshire (*Jour. Bd. Agr. [London]*, 13 (1906), No. 5, pp. 291-293).—Parasitic gastritis appears in sheep during the months of May and June, attacking most frequently ewes with young lambs. The first symptoms observed by the attendant are a lagging behind of affected sheep, a disinclination to eat, and suspension of rumination. In many cases the animals are found dead or die suddenly after the symptoms appear. Occasionally the affected sheep rally from the first attack, but the disease reappears with greater severity during the second season. The losses are estimated at from 3 to 10 per cent.

Affected animals must be considered as a source of infestation and should be removed from the rest of the flock. Some benefit is also derived from administering a tonic.

The microscopic changes in the nervous system in cases of chronic dourine as compared with those found in sleeping sickness, F. W. MOTT (*Proc. Roy. Soc. [London], Ser. B*, 78 (1906), No. B522, pp. 1-12, pls. 4).—In chronic dourine the nerve cells of the spinal cord show decided color changes, and the blood vessels exhibit evidence of inflammation, with small hemorrhages. The nerve tissue of the spinal cord becomes infiltrated with lymphocytes and all blood vessels are surrounded with small round cells. These pathological conditions are compared with those which are observed in sleeping sickness.

The destruction of *Trypanosoma brucei* in the spleen, A. RODET and G. VALLET (*Compt. Rend. Acad. Sci. [Paris]*, 142 (1906), No. 22, pp. 1229-1231).—An experimental study was made of this disease in dogs and rats. The authors found that the blood parasites are rapidly destroyed in the spleen. In fact, the spleen appears to be the most important organ in this work, although it is assisted to some extent by other organs belonging to the lymphatic system.

The treatment of trypanosomiasis with benzidin colors, M. NICOLLE and F. MESNIL (*Ann. Inst. Pasteur*, 20 (1906), No. 6, pp. 417-448).—Recently much interest has arisen in the study of the effect of various dyes upon blood parasites, particularly those of nagana, surra, and mal de caderas. The authors have made an elaborate study of the chemical composition and action of thirteen dyes belonging to the benzidin group.

The authors worked with mice which were first inoculated with one or the other of the diseases mentioned above and then given hyperdermic injections of one per cent solution of the dyestuffs in doses of one c. c. It was found that dichlorobenzidin and tolidin after one injection caused the total disappearance of the blood parasites in many cases. The action of the coloring matters was not the same when used in treating the three diseases.

Diseases caused by palisade worms in horses, F. GLAGE (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 1 (1906), No. 4-5, pp. 341-375).—A careful study was made of the anatomical characters and biology of *Sclerostomum edentatum* and *S. hidentatum*.

These worms in various stages are frequently found together in the same horse or colt, and for this reason some difficulty of identification is experienced, particularly in the larval stages. The author believes, however, that the 2 species are distinct, and offers good evidence as a basis for that belief. The parasites in question may appear in various tissues of the host, causing injury by direct removal of the blood, a production of hemorrhages, and mechanical injuries, particularly in the peritoneum. Occasionally chronic cases of general cachexia are observed as a result of infestation with these parasites.

Protective vaccine against rabies, O. HELLER (*Die Schutzimpfung gegen Lyssa*. Jena: Gustav Fischer, 1906, pp. 142).—The literature relating to rabies is critically discussed in connection with an extensive bibliography which occupies pages 92-142.

The author was chiefly concerned during his investigations in determining the cause of rabies as far as possible, and in obtaining a nonvirulent vaccine. As a result of these studies the conclusion is reached that rabies is not a bacterial disease. It appears that immunity to rabies may be brought about by the use of the material which constitutes the organism of rabies, together with the toxic substances which are produced in animals as a result of infection with rabies.

The methods heretofore used in obtaining vaccines for the control of rabies have not made it possible to obtain a vaccine which was not infectious. This has been accomplished, in the author's opinion, by the method and apparatus used by Macfadyen. After the virus has been treated with the fine sand used in this method, it loses its infectiousness, but still remains toxic, and is effective in producing immunity to rabies. Its effectiveness was shown by the author in a number of experiments on rabbits and dogs.

RURAL ENGINEERING.

Practical information for beginners in irrigation, S. FORTIER (*U. S. Dept. Agr., Farmers' Bul. 263, pp. 40, figs. 25*).—The purpose of this bulletin is to give new settlers in the arid region, particularly those coming from the humid sections of the East, such information as will enable them most successfully to adapt themselves to their changed conditions.

The writer discusses first the selection and location of an irrigated farm, with particular reference to the character and depth of soil and its topographical features, and then takes up the question of water supply, on which helpful suggestions are given as to the legal procedure necessary in the acquirement of a water right. Farm ditches are considered with respect to their capacity, form, grade, location, and the simple structures necessary.

Preparation of land for irrigation under the various systems and for various crops is described in detail, after which the methods of irrigation of the several crops receive attention. Following these, hints are given as to the best means of preventing waste of water and as to the right quantity to apply.

Drainage is advised as a means of combating most of those evils arising from rise of ground water, but economy in use of water and thorough cultivation are likewise recommended.

Reading courses in irrigation, E. MEAD (*California Sta. Circ. 20, pp. 7*).—In this circular a course of study in irrigation is outlined for the university extension in agriculture, Berkeley, Cal. A list of questions on irrigation practice and institutions is given, together with an outline of the regular course in irrigation engineering at the University of California.

Drainage investigations, C. G. ELLIOTT (*U. S. Dept. Agr., Office Expt. Stat. Rpt. 1905, pp. 197-210*).—The studies and experiments included in these investigations may be classified as follows:

"(1) Work connected with improving small natural streams and providing sufficient and adequate artificial outlets for the drainage of large areas of fertile land hitherto deficient in natural drainage which is projected and executed under the provisions of State drainage laws.

"(2) The protection of overflowed lands bordering alluvial streams, and their interior drainage after protection works have been constructed.

"(3) The solution of problems connected with the underdrainage of soils of widely different character and subject to diverse climatic conditions.

"(4) The protection and subsequent management of tidal lands, which when thus improved may be valuable for agriculture.

"(5) The drainage of lands in the arid region which under irrigation have become saturated and in consequence unproductive, and the prevention and removal of alkali occasioned by such saturation."

Of these various lines of investigation only those features of the work which are perplexing and difficult for the landowners to carry out for themselves are investigated. In some instances this Office has assisted engineers in perfecting plans and in uniting the people to carry them out. In other cases the Office has gone further and made preliminary drainage surveys and general plans for the

drainage of land in cooperation with the owners or counties where there was not sufficient understanding of the matter to either make the surveys or develop a plan of work.

Careful investigation has been made of drainage in connection with the construction of levees and the interior ditching and draining of protected land, an instance being investigations in the valley of Neosho River, Kansas. The erosion of hill lands, which is a constant menace to the stability and continued productiveness of farms, has received attention, and experiments in the drainage of a tract of such lands in Georgia have resulted in the complete restoration of their original value.

The increased tendency toward intensive production is directing the attention of owners of land in the Middle West and South to the attainment of this end by the aid of underdrainage. Difficulties have been encountered, however, in the Red River Valley of Minnesota and the Dakotas, where it is now conceded that more complete drainage than that offered by surface drainage is desirable, but where the probable efficiency of tile drains in such soils and in a climate where the ground freezes to a depth of 6 ft. is problematic. To secure information on these questions this Office proposes to establish experimental plats in the localities named, where drain tiles will be laid in various ways to determine the particular method of use giving the best results.

The prevention of damage by rise of alkali in the irrigated soils of the West is being experimented upon in Utah, Washington, and Nebraska, where such work as has already been done has shown uniformly beneficial results.

Preliminary investigations have also been made in the Kankakee Valley, Indiana, in the examination of the country and collection of information bearing upon the problems encountered in the reclamation of the Kankakee Marsh.

Report of progress of stream measurements for the calendar year 1905 (*U. S. Geol. Survey, Water-Supply and Irrig. Papers Nos. 165-178, pp. 155 + 166 + 101 + 128 + 164 + 153 + 116 + 113 + 283 + 105 + 133 + 194 + 142 + 273 + 250*).—The report consists of 14 papers published separately as parts 1 to 14. The parts cover the following subjects:

Pt. 1, Atlantic Coast of New England Drainage, H. K. Barrows and John C. Hoyt; pt. 2, Hudson, Passaic, Raritan, and Delaware River Drainages, R. E. Horton, N. C. Grover and J. C. Hoyt; pt. 3, Susquehanna, Gunpowder, Patapsco, Potomac, James, Roanoke, and Yadkin River Drainages, N. C. Grover and J. C. Hoyt; pt. 4, Santee, Savannah, Ogeechee, and Altamaha Rivers and Eastern Gulf of Mexico Drainages, M. R. Hall and J. C. Hoyt; pt. 5, Ohio and Lower Eastern Mississippi River Drainages, M. R. Hall, F. W. Hanna, and J. C. Hoyt; pt. 6, Great Lakes and St. Lawrence River Drainages, R. E. Horton, F. W. Hanna, and J. C. Hoyt; pt. 7, Hudson Bay and Upper Eastern and Western Mississippi River Drainages, F. W. Hanna and J. C. Hoyt; pt. 8, Missouri River Drainage, C. C. Babb, M. C. Hinderlider, and J. C. Hoyt; pt. 9, Meramec, Arkansas, Red, and Lower Western Mississippi River Drainages, M. C. Hinderlider, J. M. Giles, and J. C. Hoyt; pt. 10, Western Gulf of Mexico and Rio Grande Drainages, T. U. Taylor and J. C. Hoyt; pt. 11, Colorado River Drainage above Yuma, M. C. Hinderlider and G. L. Swendsen; pt. 12, The Great Basin Drainage, M. C. Hinderlider, G. L. Swendsen, and H. Thurtell; pt. 13, Great Basin and Pacific Ocean Drainages in California, and Colorado River Drainage below Gila River, W. B. Clapp and J. C. Hoyt; pt. 14, Columbia River and Puget Sound Drainage, D. W. Ross, J. T. Whistler, and T. A. Noble.

Geology and water resources of Owens Valley, California, W. T. LEE (*U. S. Geol. Survey, Water-Supply and Irrig. Paper No. 181, pp. 28 + VI, pls.*

6).—A report of field studies made in the region including Owens Valley, part of Mono Lake and Salt Wells Valleys, and the slopes of the adjoining mountain ranges. The conclusions bearing upon irrigation are as follows:

"Owens Valley is a barren desert except where it is reclaimed by the use of water entering as mountain streams. Abundant rainfall occurs in the Sierra Nevadas, yielding for this valley an annual water supply of about 400,000 acre-feet. As the streams enter the valley, they pass over unconsolidated detritus, into which much of the water sinks.

"Flowing wells occur in Owens Valley, but the limits of the district in which such wells are obtainable are undetermined.

"A large amount of underground water exists without hydrostatic pressure sufficient to produce flowing wells, but power for pumping this water can be produced from the mountain streams and transmitted to the valley at moderate cost.

"Owens Lake has been decreasing in volume for several years, with a corresponding increase in the density of its water. The salinity has reached a point at which the more insoluble salts precipitate. The change is probably due to the loss by evaporation of water diverted for irrigation and not to an increase in the aridity of the climate, as originally supposed.

"The proposed Owens Valley reservoir, being located in the fault zone at the base of the Sierra Nevada, would be especially liable to injury from crustal movements."

Turbine water-wheel tests and power tables, R. E. HORTON (*U. S. Geol. Survey, Water-Supply and Irrig. Paper No. 189, pp. 131, pls. 4, figs. 33*).—A discussion of turbine water wheels, with special reference to their use as water meters. Various types of wheels are described, results of various tests are given, and manufacturers' tables of power, speed, and discharge are included.

The development of the test for the cementing value of road material, A. S. CUSHMAN (*Engin. Rec., 53 (1906), No. 25, pp. 760-762*).—A paper read before the American Society for Testing Materials.

The author reviews the earlier attempts to develop a test for the cementing values of the dust of abraded material. These first tests consisted in general of mixing road dust with water and molding the dough into small briquettes, which, after being dried, were tested to destruction by repeated impacts of a hammer weighing 1 kg. and falling 1 cm. Certain discrepancies having been found in the results obtained by this method, more care was taken in the mixing. It was found that the binding power could be increased by prolonged kneading, corresponding to the characteristics of dolomite in actual use, the binding power of which has been observed to increase after it has been on the road some time. Later still, a method of wet grinding was introduced, the "charge of rock dust being ground with approximately 20 per cent by weight of water in a ball mill for 3 hours." By this method the binding power was increased, confirming the idea general among road engineers that the more wet rolling to which the rock-road material can be subjected, the better the resulting road.

The latest developments in grinding are porcelain pebble mills which have been substituted for the heavy and cumbersome ball mills. A recent series of experiments has developed a field of investigation which, according to the author "promises to be of great interest both on the theoretical and practical sides." "It appears that the addition of lime or limestone will greatly increase the cementing value of an acidic rock like granite." The results that are shown in the table were obtained by mixing together limestone and granite rock powders of known cementing value and grinding the mixture with water.

Cement values of mixed rock dusts.

Limestone.	Granite.	Combina- tion.
20	6	82
26	7	53
22	9	56
13	10	22
27	3	110
26	7	38

In the opinion of the writer, these results indicate that "the road builder should blend his material, so as to bring about the greatest amount of decomposition possible among the road particles on which he depends for the formation of the bonded surface of his road."

The construction of sand-clay and burnt-clay roads, W. L. SPOON (*U. S. Dept. Agr., Office Pub. Roads Bul. 27, pp. 19, pls. 4, figs. 5*).—This bulletin discusses the investigations made by the Office of Public Roads on the use of a mixture of sand and clay for the improvement of roads, and upon the utilization of burnt clay for road construction.

By the use of a proper mixture of sand and clay it has been found possible to construct roads through localities where the prevailing soil is either sand or clay or an objectionable mixture of both. These roads are well adapted for light traffic, are less noisy, less dusty, and more resilient than the average macadam road. The best sand-clay road is one in which the wearing surface is composed of sand, and in which the spaces between the particles are entirely filled with clay. Such a mixture is best secured by thoroughly mixing the right proportion of the two ingredients with water. In practice the clay is first spread on the road and the larger lumps broken up. The surface is spread with a few inches of sand immediately after a hard rain, and the mixture then thoroughly stirred by a turning plow or disk harrow. The cost of sand-clay roads varies with local conditions, but may be taken at \$300 to \$800 per mile, the character of the foundation, whether sand or clay, making no difference in the cost.

In the improvement of roads through "gumbo" soils of the Yazoo district of Mississippi, simple burning of the clay upon the road surface was resorted to. Wood, procured adjacent to the road, is used as fuel, 1 cord being required per 8 linear ft. of a 12-ft. road. After deeply plowing the road transverse furrows are formed, across which the wood is laid. Lumps of clay and more wood are piled on this. A third layer of wood parallel to the first is then put on and finally covered with a layer of finer clay to a depth of not less than 6 or 8 in. Fifteen to twenty flues are fired at once, and the process of combustion made as uniform as possible. After the burning process is complete, the material, which is entirely changed in character, having no tendency to form mud when wet, is rolled down and compacted, forming a road surface 6 to 8 in. in thickness.

The total cost per mile of such construction, as based on the experiments carried on, is \$1,478. It is thought that any soil which bricks or clinkers at comparatively low temperature is suitable for the work. Roads constructed by this method are said to be successful so far and to sustain traffic in even the wettest weather.

Waterproof roads as a solution of the dust problem, D. MACKENZIE (*Engineer [London], 102 (1906), No. 2643, pp. 185, 186*).—A paper read before the British Association, York, 1906, in which the author discusses the question of obviating the dust nuisance.

After commenting upon the failure of the oil or tar treatment because of its short period of usefulness and objectionable features from the standpoint of

cleanliness, the author concludes that "the great mistake has been in the use of tar as it is usually sold. Much better results have been found where the tar is distilled, but what is required is the addition of some material that will toughen the tar in much the same way that pitch is toughened for insulating purposes."

The evolution of farm-implement investigations, C. J. ZINTHEO (*U. S. Dept. Agr., Office Expt. Stas. Rpt. 1905, pp. 211-223*).—The economic conditions under which the American farmer is placed necessitate the extensive use of labor-saving machinery. Notwithstanding the large investments in such machinery and farm implements, there is little available information on their utility and efficiency.

The author describes the implement-testing laboratories in the different countries of Europe, giving information on the methods pursued and results accomplished in such tests. Some needed investigations are then considered in the testing of tillage, seeding, and planting implements, of harvesting and thrashing machinery, and of the motive powers for farm use. In connection with the last named, the question of using alcohol for fuel is briefly touched upon.

In conclusion the author states that the needs of this country in farm-machinery investigations are somewhat peculiar. American inventors have developed and supplied the farmers with a great variety of machines, but little is known as to which of the various types will best meet the requirements of different soil and crop conditions. "Such investigations would also form the basis for the development of new types of machines with which to meet the requirements of modern methods of agriculture, and thus to increase the yield of crops and reduce the cost of production."

Instructions to engineers of timber tests, W. K. HATT (*U. S. Dept. Agr., Forest Serv. Circ. 38, pp. 55, figs. 17*).—A manual for engineers engaged in the testing of timber. The instructions cover tests to determine "the relation between the physical characteristics of wood and the mechanical properties, and the effect of various technological operations upon them; to establish authoritative data for design; to collect data for the improvement of specifications for market products; to study the best methods of testing; and to determine what species may be used as substitutes for those now becoming scarce."

RURAL ECONOMICS.

Some present problems in agriculture, L. H. BAILEY (*Congress of Arts and Science. Boston and New York: Houghton, Mifflin & Co., 1906, vol. 6, pp. 727-738*).—This is a paper read before the section of agriculture at the St. Louis Purchase Exposition in 1904.

The author discusses the technical problems of agriculture and the problems of adjustment to the affairs of our growing civilization. Chief among technical problems are discussed: Methods of feeding to increase the efficiency of farm animals, the breeding of animals and plants for the same purpose, and the business organization of the farm, or development of a farm plan.

"The greatest problems of American agriculture [however] are not the narrower technical ones, but the relations of the industry to economic and social life in general." Along this line, according to the author, education, cooperation, investment of capital, farm labor, making country life attractive, better schools, and the production of a more natural agricultural literature are problems which press for solution. Government aid as a means to the solution of these technical and economic problems of agriculture is advocated.

Agricultural development and the social welfare of the farmer, P. DE VUYST (*Rev. Gén. Agron., n. ser., 1 (1906), No. 6-7, pp. 305-319*).—The author

reviews the course of agricultural evolution that has taken place in Belgium during the past 20 years, and shows how the changes have operated to improve the moral and social welfare of the rural population.

Among the causes of improvement brought about by the department of agriculture and the organization of farmers into unions and mutual aid societies are mentioned the popularization of scientific agricultural knowledge, the use of commercial fertilizers, breeding of improved cattle, new processes in the manufacture of dairy products, feeding experiments with dairy cows, and the raising of crops adapted to local conditions. The results are shown in greatly increased products, which directly affect the economic well-being of the producers.

Improvement in the social welfare of farmers and farm laborers has been due to information imparted in popular form regarding domestic hygiene, to the beautifying of homes and home surroundings, to a better standard of living, to the improved relations between proprietors, tenants, laborers, and the general public, and to the more numerous opportunities for social intercourse afforded by the various rural organizations. The progress made in these directions is briefly noted not only for Belgium, but for many other European countries and the United States.

Besides copious notes referring to the literature of the subject an extended bibliography is appended.

The negro farmer, W. E. B. DU BOIS (*Supplementary Analysis and Derivative Tables. Bur. of the Census [U. S.], 1906, pp. 511-579, maps 3*).—The author gives statistics relating to the number of farms operated by colored farmers in the United States in 1900, total acreage and acreage under crops, value of farm property, and the value of products raised, and discusses many other matters bearing upon the economic development of the race from 1865 to 1900.

Of the 746,715 farms operated by negroes, 21 per cent were owned entirely, 4.2 per cent were owned in part, and 716,514 were improved by buildings. They contained 38,233,933 acres, of which 23,362,798 acres, or 61 per cent, were improved. The total value of farms and improvements was \$499,943,734, and the gross value of products raised in 1899 was \$255,751,145. "The Southern States contain more than 98 per cent of all farms operated by negroes and more than 97 per cent of the total acreage of these farms."

Reasoning from these facts and figures and reviewing a detailed study of ownership county by county the author finds two kinds of conditions prevailing in the black farming belt: "In the one case . . . economic conditions are favorable and the negroes migrate to or remain in the region and enjoy there a fair degree of agricultural prosperity; in the other case the economic conditions are less favorable, but they render emigration difficult by providing little education for the negroes, and by a general resort to the crop-lien system, under which the acquisition of landed property by negroes is impeded by the high value of land."

Prussia and its agricultural relations, A. MEITZEN ET AL. (*Der Boden und die landwirtschaftlichen Verhältnisse des Preussischen Staates. Berlin: Paul Parey, 1906, pts. 1, pp. XIV + 901, figs. 16; 2, maps 27*).—This publication consists of a series of papers by various authors giving statistical data and discussions which relate to the development of agriculture in Prussia.

The following topics are treated in Part 1: Progress in the knowledge of plant and animal nutrition; culture and use of field crops from 1878 to 1900; the development of agriculture since 1866; drainage, irrigation, and high-water protection; moor cultivation; vegetable, fruit, and grape culture; extent and management of forests; cattle breeding, improvement, and statistics; veter-

inary science; fishing and fish culture; and agricultural production, including detailed statistics on the yields of the most important products.

Part 2 consists of 27 colored maps illustrating the data contained in vols. 5-8 of this publication.

The development of agriculture for the five years 1901 to 1905 (*Jahresber. Landw. Kammer Wiesbaden, 1905, pp. 143-319*).—A report is given on the progress of agriculture in the district of Wiesbaden.

Statistics are presented and discussed relating to the population and the natural and economic conditions of crop production, including data on the production, transportation, and monthly and annual prices of the most important agricultural products, such as cereals, cattle, meat, milk, potatoes, butter, eggs, wine, fruit, etc., and the extent of the use of feeding stuffs and fertilizers. Data are also given on the selling and renting values of land; agricultural labor, legislation, schools, and research institutions; cooperative banking, credit, and insurance societies; farm management, breeding and improvement of farm animals, and the technique and profitableness of agriculture.

Crop Reporter (*U. S. Dept. Agr., Bur. Statis. Crop Reporter, 8 (1906), No. 6, pp. 41-48; 7, pp. 49-56*).—These numbers for October and November, 1906, contain in addition to the usual statistics on the yields and condition of crops in the United States and foreign countries the following special articles: Crop export movement, 1905-6; stocks of American cheese, Sept. 30, 1906; per capita consumption of rice; cotton area of British India for 1906-7 crop; rice in the Philippine Islands; the Australasian wheat crop; peanut imports; tobacco crop by types—average production in 1906; the beet-sugar crop; the hop movement in the United States, 1900-1906; and other topics of an agricultural nature.

Cotton movement and fluctuation, 1901-1906 (*New York: Latham, Alexander & Co., 1906, pp. 184, pls. 6*).—This publication contains detailed statistics and special articles relating to cotton production, consumption, manufacture, and prices in the chief markets of the world, but particularly with reference to the cotton industry in the United States. For the year ended August 31, 1906, a summary of our trade in cotton and cotton goods is given as follows: Total crop 11,345,988 bales, value \$600,000,000; export trade 6,716,351 bales, value \$400,000,000; southern consumption 2,398,404 bales, northern consumption 2,499,768 bales; value of manufactured cotton goods exported \$53,000,000.

AGRICULTURAL EDUCATION.

Progress in agricultural education, 1905, A. C. TRUE (*U. S. Dept. Agr., Office Expt. Stas. Rpt. 1905, pp. 303-357, pls. 5*).—A review is given of the educational work of this Department in its relation to both American and foreign educational institutions, including brief accounts of the Second International Congress of Agricultural Education and the First International Congress of Agricultural Mechanics, both held at Liege, Belgium, in 1905. Attention is given to the educational work in 1905 of the Association of American Agricultural Colleges and Experiment Stations, and the progress along agricultural lines made by the agricultural colleges and by secondary and primary schools. The article also contains a course of study for rural schools, prepared by Prof. W. M. Hays for the National Educational Association. This course provides an articulated scheme for the consolidated rural school, the agricultural high school, and the agricultural college.

Statistics of land-grant colleges and agricultural experiment stations, 1905, MARIE T. SPETHMANN (*U. S. Dept. Agr., Office Expt. Stas. Rpt. 1905, pp. 153-186*).—These statistics relate to the courses of study at the agricultural colleges, number of students in attendance, value of permanent funds and equip-

ment, revenues for the year, etc.; and the lines of work and publications of the experiment stations, their revenues, additions to equipment, and classification of expenditures for the fiscal year.

The total number of institutions maintaining courses in agriculture is 63, with a total income in 1905 of \$11,767,154.54. The total number of persons in the faculties of the colleges of agriculture and mechanic arts was 2,672, and in other departments 1,889, making a grand total of 4,561 persons in the faculties of the land-grant institutions. The enrollment of students in colleges for white persons was 53,518, and in colleges and schools for colored persons, 6,294.

The total number of experiment stations is 60, exclusive of substations, and of these 55 receive the benefit of the Hatch Act. The total income of these stations during 1905 was \$1,515,734.47, of which \$718,163.45 was received from the National Government. In addition to this, the Office of Experiment Stations had an appropriation of \$177,500, including \$15,000 each for the Alaska, Hawaii, and Porto Rico stations, \$20,000 for nutrition investigations, \$67,500 for irrigation investigations, and \$5,000 for farmers' institutes. The stations employed 845 persons in the work of administration and inquiry, of whom 423 did more or less teaching in the colleges with which the stations are connected. During the year the stations published 403 annual reports and bulletins, which were supplied to over 731,000 addresses on the regular mailing lists.

School agriculture (*Agr. Gaz.*, N. S. Wales, 17 (1906), No. 9, pp. 905-910, figs. 6, dgm. 1).—An account is given of the success attained by Mr. John Halsted, while teacher of the public school at Eglinton, in teaching elementary agriculture, horticulture, floriculture, arboriculture, and apiculture. The account includes an outline showing the methods employed, a weekly lesson from the program illustrating the correlation of practice and theory, and a syllabus of the two-year course.

Agriculture, a school subject, C. W. BURKETT (*Industrialist*, 33 (1906), No. 6, pp. 83-90).—Two reasons are given for considering agriculture a good subject to teach in schools, viz. that it affords in a preeminent way (1) a wide field for accurate, interesting, and uplifting knowledge, and (2) a wide field for doing. Agriculture is a cultural subject because it is "concerned with the highest truths that the mind can consider, namely, the laws of life, of growth, of heredity, of adaptation, of selection, of environment." It is also a practical subject because of the direct application of its principles to life and because it shows the relation between cause and effect.

Suggestions are given to the teacher for the use of the text-book in teaching agriculture, for written work in connection with the text-book work, and for experiments both at school and at the homes of the children.

Outline for instruction in elements of agriculture for the use of teachers in common schools, C. P. CARY (*Wis. State Supt. Pub. Instr.*] *Bul.* 13, pp. 24, figs. 2).—The Wisconsin law of 1905 requiring the teaching of agriculture among the branches of study in public schools is interpreted, and an outline for this subject is given. It is recommended that agriculture be taught in the last half of the eighth year, and that nature study be given in all grades through general exercises and in connection with language exercises, geography, reading, and history.

The outline is divided into three parts: (1) Agriculture, including the soil, water and the soil, tilling the soil, soil enrichment, the plant, the leguminous plants, plant enemies, rotation of crops, selection of seed, the farm garden, weeds, and home and school garden; (2) farm animals, including care and feeding, type forms, and farm economies, and (3) farm poultry. A bibliography of reference books and bulletins on the topics mentioned in the outline is given.

Agriculture in rural schools, D. J. CROSBY (*Farmers Voice*, 44 (1906) No. 20, pp. 7, 8, figs. 3).—The writer discusses the trend in modern education toward concreteness in the primary and secondary schools, and the feasibility of teaching agriculture in rural schools, giving examples of successful work along this line and reviewing briefly the present status of school work in agriculture.

Report of the committee on industrial education: School gardens (*Pub. Ed. Assoc. Phila., Ann. Rpt.*, 25 (1906), pp. 32, 33).—A summary of the school garden work under the control of the Board of Public Education in Philadelphia in 1905.

During the year the number of school garden centers was increased from 2 to 10 and a training class for teachers was conducted. Most of the garden work was done outside of school hours, and it thus gave the children "an adequate substitute for the alluring but demoralizing street life that is their only alternative until they are fourteen years old and able to go to work." The garden work was in some cases closely correlated with the schoolroom work.

Each garden had 250 individual plats averaging $4\frac{1}{2}$ by 12 ft., and a playground open to all children in the neighborhood. Pupils in primary grades visited the gardens with their teachers for nature study lessons and garden products were sent to the schools for study.

Status of veterinary and agricultural instruction, VAN DER BRUGGEN (*Rapport Triennal sur l'Enseignement Veterinaire et sur l'Enseignement Agricole. Brussels: J. Goemaere, 1906, pp. XXXII + 216*).—This is a triennial report on veterinary and agricultural instruction in Belgium.

The report includes detailed information concerning collegiate, secondary, primary, and itinerant instruction in veterinary science, agriculture, and horticulture throughout the Kingdom; also the educational features of expositions, the publications of the department of agriculture, and the inspection of agricultural institutions. In the appendixes reports on courses of study, attendance, income, and other important matters are given for each institution under the direction of the department.

Agricultural education in Denmark and Sweden, J. SÆLAND (*Tidsskr. Norske Landbr.*, 13 (1906), No. 6, pp. 245-262).

Twenty-five years of Tuskegee, B. T. WASHINGTON (*World's Work*, 11 (1906), No. 6, pp. 7433-7450, figs. 23).—A review of the work at the Tuskegee Normal and Agricultural Institute since it was started, and an account of the influence of the school upon the negroes of the South, with a list of similar institutions started and conducted by graduates of Tuskegee.

What Hampton means by education, A. SHAW (*Amer. Mo. Rev. of Reviews*, 34 (1906), No. 3, pp. 305-314, figs. 17).—After discussing the educational problem in the South, the writer takes up the kind of education given at Hampton, dwelling especially upon the training of teachers for negro schools and the undergraduate agricultural course.

The army training schools at Fort Riley, C. S. WEST (*World To-Day*, 11 (1906), No. 4, pp. 1052-1058, figs. 7).—This is a description of the training school for bakers and cooks, and of the training school for farriers and horseshoers, established by the War Department in connection with the School of Application for Cavalry and Field Artillery, at Fort Riley, Kans.

The school for bakers and cooks extends over a period of 4 months and includes instruction in the various processes of baking and cooking with a variety of apparatus and utensils, such as would be found in garrison service or in the field.

The school for farriers and horseshoers consists of 2 terms of 4 months each, and is composed of classes of especially recommended enlisted men, who are instructed in the anatomy and physiology of the horse, causes and treatment of

diseases, wounds, etc., as well as the different kinds and uses of horseshoers' tools and the processes of shoeing to meet different conditions and needs.

Teaching the rudiments of cooking in the class room, ESTELLE REEL (*Washington: Govt. Printing Office, 1906, pp. 62*).—Primary methods and outlines prepared as a guide for teachers in the Indian schools, who are urged to give attention to instruction in cooking as one of the features of regular class-room work. The work is included in all years of the Indian school work. Sample lessons are given, as are also outlines of courses in cooking used in Chicago schools, at the Hampton Normal and Agricultural Institute, and in rural schools about Norfolk, Va.

Agricultural practices and morals, E. J. WORTLEY (*Kingston, Jamaica: Educational Supply Co., 1906, pp. 2½, figs. 6*).—A manual of practice for use in the public schools of Jamaica.

Agriculture in our public schools, E. J. KYLE (*Gulf Coast Line Mag., 2 (1906), No. 2, pp. 71-78*).—A discussion of the need of teaching agriculture in public schools, suggestions for garden work from September to May, a list of six suitable text-books for use in this connection, and a syllabus for an elementary course in agriculture taken from Circular 60 of this Office.

Concerning nature study and primary agriculture, T. H. SCHEFFER (*Industrialist, 33 (1906), No. 1, pp. 3-9*).—This is an interpretation of the causes of discontent with rural life and an effort to find a partial remedy for this condition through the introduction of nature study and elementary agriculture into the rural schools. The article is suggestive of methods of presenting these subjects and dwells upon the importance of pleasant surroundings for both school and home as an element in creating a love for the country.

Report of the committee on school gardens and native plants for the year 1905, H. S. ADAMS (*Trans. Mass. Hort. Soc., 1906, II, pp. 113-293, pls. 9*).—This is the last report of the Committee on School Gardens and Native Plants, it having been decided to discontinue the work with children's herbariums and native plants and confine the efforts of the committee henceforth to the encouragement of gardening among children both in school and at home.

The report for 1905 deals with children's school gardens, home gardens, herbariums, and exhibits of native plants. Abstracts are given of addresses made at a children's garden conference held in Horticultural Hall, Boston, December 2, 1905. The subjects of these addresses are as follows: School Garden Work in Boston Schools, by Miss Esther F. Hallowell; School Gardens as a Preparation for College, by F. A. Waugh; The School Garden as a Factor in Village Improvement, by Philip Emerson; Children's Gardens from Frost to Frost, by H. D. Hemenway; School Garden Work in Cleveland, Ohio, by Miss Louise Klein Miller; Children's Garden Exhibitions, by A. H. Hixon; School Garden Notes, by F. M. Marsh, and Ten Minutes in a Boy's Garden, by Miss Elizabeth S. Hill.

The report also includes reports on school gardens at Cobbett School, Lynn, Groton, Lincoln, and Sewall schools at Brookline and Fairhaven.

The report closes with a number of accounts of children's home gardens and a list of prizes and gratuities awarded in 1905.

An outline in garden study, BERTHA M. BROWN ET AL. (*Hyanis, Mass.: Author, 1906, folio*).—This is a chart prepared by the teachers of the State Normal School, Hyannis, Mass., showing diagrammatically how school garden work may be related to other subjects in the primary school.

School gardens, W. W. LIVINGSTONE (*Agr. Econ., 39 (1906), No. 44, p. 277, fig. 1*).—The writer discusses the value of school gardens as aids in nature study teaching and describes briefly the nature of such work in Staffordshire and Surrey counties, England.

Gardens for city schools, H. G. PARSONS (*Nature-Study Rev.*, 2 (1906), No. 6, pp. 204-206).—Suggestions for planting and managing a small garden connected with a school of 1,500 children in the city.

A city school garden (*Md. Agr. Col. Bul.*, 3 (1906), No. 1, pp. 1-24 figs. 19, dgm. 1).—This bulletin contains an introduction by R. W. Silvester, which is followed by an account of the school garden work at School No. 33, Baltimore, Md., by Miss Virginia McGaw.

Nature study and high school chemistry, A. SMITH (*Nature-Study Rev.*, 2 (1906), No. 6, pp. 193-198).—This is an article dealing with the kind of instruction in nature study that the author would like students to have before taking up chemistry in the high school. He does not favor attempting to teach many facts concerning the elements of chemistry, but would have exercises in all phases of nature study conducted in such a way as "to keep 'the tentacles of inquiry' functional, if not to develop them."

The farmers' institutes in the United States, 1905, J. HAMILTON (*U. S. Dept. Agr., Office Expt. Stas. Rpt. 1905*, pp. 359-413).—An account is given of the work of the Farmers' Institute Specialist of this Office, of the meeting of the American Association of Farmers' Institute Workers in 1905, and of the progress of the farmers' institutes in the different States and Territories, including statistical data regarding the number of institutes, the attendance, the number of lecturers employed, and the financial support of the institutes.

The farmer's reading course, S. W. FLETCHER (*Mich. Bd. Agr., Inst. Bul.* 12, pp. 70-74).—Suggestions for conducting reading courses for farmers and for farmers' wives, based largely on the courses conducted by the New York State College of Agriculture at Cornell University.

MISCELLANEOUS.

Annual Report of the Office of Experiment Stations, 1905 (*U. S. Dept. Agr., Office Expt. Stas. Rpt. 1905*, pp. 413, pls. 11).—This includes the usual report on the work and expenditures of the Office of Experiment Stations and the agricultural experiment stations in the United States, including Alaska, Hawaii, and Porto Rico; statistics of the agricultural colleges and experiment stations for 1905; a brief account of the nineteenth annual meeting of the Association of American Agricultural Colleges and Experiment Stations; and several articles and reviews abstracted elsewhere in this issue. The report is preceded by a general summary.

Seventeenth Annual Report of Connecticut Storrs Station, 1905 (*Connecticut Storrs Sta. Rpt. 1905*, pp. 224).—This contains the organization list of the station, a list of station publications available for distribution, a financial statement for the fiscal year ended June 30, 1905, reports of the director and heads of departments, and several articles which are abstracted elsewhere in this issue or have already been noted from other sources (*E. S. R.*, 17, pp. 79, 388, 1186).

Thirteenth Annual Report of Minnesota Station, 1905 (*Minnesota Sta. Rpt. 1905*, pp. XIII+283).—The report of the director includes the financial statement for the fiscal year ended June 30, 1905, and summaries of the work of the different divisions and of the northwest and northeast experiment farms. Reprints of Bulletins 87-92 of the station are appended.

Eighteenth Annual Report of Mississippi Station (*Mississippi Sta. Rpt. 1905*, pp. 35).—This contains the organization list, a brief report of the director, a financial statement for the fiscal year ended June 30, 1905, and reports of heads of the departments containing experimental work, abstracted elsewhere. A report of the work at McNeill Substation is also included.

Twelfth Annual Report of Montana Station (*Montana Sta. Rpt. 1905, pp. 230-296*).—This contains the organization list and financial statement for the fiscal year ended June 30, 1905, a report of the director on the general work of the station during the year, lists of station publications, donations, and exchanges, and departmental reports, the experimental work of which is noted elsewhere in this issue.

Sixteenth Annual Report of New Mexico Station, 1905 (*New Mexico Sta. Rpt. 1905, pp. 35*).—This includes a report of the director on the work and publications of the station, a list of station publications available for distribution, departmental reports on the various lines of station work conducted during the year, and a financial statement for the fiscal year ended June 30, 1905.

Experiment Station Work, XXXVI (*U. S. Dept. Agr., Farmers' Bul. 262, pp. 32, figs. 2*).—This number contains articles on the following subjects: Water for table use, phosphates, winter wheat, glutenous and starchy wheats, dry farming, methods of canning, beet molasses and pulp, feed lots, guinea fowls, color of eggs, spraying for scale insects, and white pine in New England.

NOTES.

Alaska Stations.—J. W. Neal, who has been in charge of the Copper Valley Station from its inception in 1902, has resigned to take effect February 1. His successor has not yet been appointed.

At the Rampart Station all varieties of grain grown—that is, winter wheat, winter rye, barley, and oats—are reported to have matured during the past season, as during the 6 years previous, while at Copper Valley, $3\frac{1}{2}^{\circ}$ farther south, grain was again killed by frost occurring about the middle of August. The reason for this anomaly is not apparent. The work of the Alaska Stations indicates that there are considerable variations of climate in different parts of the Territory and that the possibilities of each portion can not be foretold with accuracy until each is tested. The development of early maturing varieties of grain is one of the important problems which the stations are attempting to solve.

Connecticut Storrs College and Station.—J. M. Trueman of the Illinois University and Station has been appointed dairy husbandman in the college and station, and will assume his duties April 1.

Delaware Station.—Margaret B. MacDonald, Ph. D., has recently been appointed assistant chemist.

Florida Station.—The office of the director has been installed at Gainesville, and this will henceforth be the address of the station. John M. Scott, of the New Mexico College and Station, has assumed charge of the work in animal husbandry.

Hawaii Station.—Edmund C. Shorey has resigned his position as chemist.

Indiana Station.—Arrangements have recently been made with one of the railroads of the State to run a seed-corn special over its entire system, beginning February 25. This includes a trip of some 1,500 miles and will require about 15 days. The corn trains already sent out have created very widespread and intense interest among the farmers of the State.

Kansas Station.—A second egg-laying contest has just been inaugurated, to continue for one year. Pens of six hens and a cockerel of each of 24 breeds have been entered. Trap nests are provided so that the contest will be also a test of individuals as well as of the cost of egg production.

Maryland Station.—C. P. Close, horticulturist at the Delaware Station, has succeeded W. N. Hutt as horticulturist, the latter having resigned to accept a similar position with the North Carolina department of agriculture and experiment station, as previously noted.

Missouri University and Station.—The State board of agriculture has recommended an appropriation of \$226,000 for the college of agriculture, \$200,000 to be used for an agricultural building. B. R. Thompson, a graduate of the Kansas College, has been appointed assistant in dairying in the college, and R. C. Donaghue, of the University of Ohio, assistant in agronomy in the station.

Nebraska Station.—A decision of the supreme court of the State affecting the

Adams fund is of interest to stations whose funds are deposited with the State treasurer. The State auditor of Nebraska declined to pay out the Adams fund from the State treasury on the requisition of the board of regents, on the ground that the legislature had not specifically appropriated the fund. The supreme court in a decision rendered November 10, 1906, held that "the fund never belonged to the State," but "was paid to the State treasurer as the agent of the board of regents and custodian of the funds of the university," and that in view of the nature of the fund, and a previous act of the legislature relating to the funds of the station derived from the Hatch Act, or supplemental acts, "it seems clear that in general terms the expenditure of said fund by the board of regents is clearly authorized, and no other or more specific appropriation is necessary." (Decision in *Northwest Reporter*, Dec. 18, 1906, p. 770.)

Recent appointments to the station staff include A. F. Magdanz, assistant in animal husbandry; L. B. Sturdevant, assistant in animal pathology; and F. E. Denny, assistant in horticulture.

Nevada Station.—The resignation of N. E. Wilson, consulting chemist, is announced. Dr. W. B. Mack, of Cornell University, has accepted the position of veterinarian and bacteriologist, and assumed his duties January 1.

New Hampshire College and Station.—The resignation of Ivan C. Weld, in charge of dairy manufactures, is reported.

Cornell University and Station.—*Cornell Countryman* states that S. M. Herrick, assistant in agricultural chemistry, has become assistant chemist at the Virginia Station.

Ohio University.—A recent communication from the president of the Percheron Horse Society of France announces that the society has voted to offer to the department of animal husbandry of the university an object of art representing a Percheron horse. This trophy will probably be a bronze figure of a Percheron, and is to be competed for annually by the students taking instruction in horse judging at the university, the one showing the greatest proficiency having his name inscribed on the base of the trophy. This action of the society is the outgrowth of a visit to this country in 1904 of Mr. Charles Aveline, its president, who became interested in the educational work of the university upon the horse.

Oklahoma Station.—Work has been begun on a small horse barn to provide for new work under the Adams Act in connection with a study of some of the problems of breeding animals. This work will include a study of the use of the artificial impregnator, and of the effect of various kinds of feed on the breeding powers of animals.

Porto Rico Station.—H. C. Henriksen has resigned as horticulturist to enter the service of the German Kali Syndicate, and is succeeded by Martin J. Iorns, a recent postgraduate student at Cornell University.

Rhode Island Station.—H. L. Barnes has resigned as assistant horticulturist. F. R. Pember, for some years in the employ of the Bureau of Soils, has accepted a position at this station in connection with the soil investigations.

Utah College and Station.—W. M. Jardine, agronomist in the college and station, has resigned to accept a position as assistant cerealist in the Bureau of Plant Industry. Willard C. Snow, assistant chemist, resigned November 1 to engage in private work.

A new publication entitled *Rocky Mountain Farming* has been started by the faculty. It is aimed to make it a general farm paper for the Rocky Mountain intermountain region, to serve also as the organ for college extension work. The contributors are principally members of the station staff and the faculty, and students of the institution.

Vermont Station.—The State legislature has, by a joint resolution, assented to the purposes of the Adams Act, and designated the station as beneficiary, and has appropriated \$500 annually for the next 5 years for the establishment and maintenance of a nursery for the distribution of forest seedlings. The latter will be located upon a farm owned by the university.

International Live Stock Exposition.—The seventh exposition of the International Live Stock Association, held in Chicago during the week of December 3, proved even more successful than those of previous years. The number of entries was 30 per cent greater than ever before, the increase being especially noticeable in sheep. The quality of the stock exhibited also showed improvement in most classes. In spite of the doubling of the price of admission and of an additional charge for reserved seats, popular interest seemed unabated, and the attendance broke all records, thousands being turned away each day. Plans to enlarge the amphitheater by one-third are now under contemplation.

At a meeting of the directors of the association a new plan of organization was decided upon. A new board was elected, consisting of 24 members, chosen for terms ranging from 1 to 3 years, so that in future only one-third will be elected each year. Prof. C. F. Curtiss, of Iowa, a former director, was among those elected for 2 years.

The influence of the agricultural colleges and stations was again strongly in evidence throughout the exposition. A considerable portion of the judges were taken from their ranks, and their exhibits attracted widespread interest. Previous to the exposition a petition had been sent in by exhibitors to debar the colleges and stations from the open competitions, but this was not granted, and in nearly all classes a large proportion of the prizes fell to their share.

In the fat-stock division their predominance was especially marked. In the display of fat barrows Ohio State University furnished the champion Berkshire, and Iowa State College the champion pen of 3. In Poland Chinas and Duroc Jerseys all championships went to Iowa. North Dakota took a second on a pen of large Yorkshires, and Wisconsin a first and second and the championship for the Tamworths. The grand championship for a pen of 3 barrows, all breeds, was awarded to Iowa. In dressed hogs Wisconsin was first for carcasses of 300 lbs. and over. Iowa took second in this class and first for carcasses from 200 to 300 lbs. in weight.

For fat wethers Wisconsin took two seconds and a third for Shropshires, second on a pen of 5 lambs of Southdowns, and third for yearling Hampshires, and in Cheviots first for yearlings, second and third for lambs, first for a pen of 5, and the breed championship, besides 11 prizes for grades and crossbreeds. Iowa was awarded first for yearling Oxfords. For dressed sheep Iowa took second and third for wethers, and Wisconsin first for lambs and the champion carcass of the show.

In fat cattle, Kansas took a first and 2 fourths for Shorthorns, besides a second on herd. Nebraska received a second, Purdue a second and third, and Ohio a first. Iowa and Minnesota won first in the Hereford class, and Purdue a fifth. For the Aberdeen Angus, Minnesota carried off first for 2-year-olds and yearlings, and the breed championship for single steers and herds. Kansas took first in Angus calves, and Nebraska a fourth. Ohio won first for 2-year-olds and the breed championship with Galloways, Minnesota receiving a third. In the 2-year-old class for grades and crosses, Kansas won first, North Dakota second, and Iowa fifth.

For senior yearlings Ohio was second and Minnesota third, and for junior yearlings Iowa took first and fourth, Purdue and Kansas capturing second and third. Nebraska was first in the class for junior calves, Iowa third, and Purdue fourth. Iowa won first and fifth for herds, and the champion herd of the

show for all breeds was from Minnesota. For the first time in the history of the show, grand championship honors went to a calf, Peerless Wilton 39th's Defender, a Hereford, since sold to the Iowa College. The second choice was an Angus yearling, Andy, owned by the Minnesota Station.

In the breeding stock section the entries from the colleges were less numerous. Purdue secured a third on aged Shorthorn bulls, and Wisconsin and North Dakota carried off several special prizes for American Rambouillets. In response to a general demand from swine breeders, arrangements were made whereby the classes for breeding swine, which were discontinued 2 years ago because of the danger of transmission of infectious diseases, are to be restored under certain restrictions.

The special classes for college and station stock were again continued, and resulted in an even larger number of entries and sharper competition than ever. In the class for 2-year-old cattle Nebraska was first, Minnesota third, and Kansas second and fourth. For yearlings Minnesota took first, second, and fourth, and Nebraska third. Kansas took first and third for calves, Minnesota second, and Nebraska fourth. For a pen of 5 steers the first place went to Minnesota. Nebraska furnished the champion of the college steers, Ruby Zenoleum. Wisconsin was awarded all prizes for sheep. For swine Iowa received first for a barrow under 12 months, Ohio second, and Wisconsin third. For a pen of 5 Iowa was first, followed by Wisconsin and Ohio, and the champion barrow was from Iowa.

As in previous years, the students from the colleges were most liberally represented. Iowa, Illinois, and Minnesota sent over 100 each, and smaller delegations came from Virginia, Wisconsin, Indiana, Ohio, Michigan, Missouri, Texas, Colorado, Nebraska, North Dakota, Kansas, and Ontario. During the exposition the American Federation of Agricultural Students held an enthusiastic meeting.

The students' stock-judging contest was participated in by 6 institutions. Ontario Agricultural College led in the work with cattle and sheep, and once more scored the highest total of points, followed by Iowa, Ohio, Kansas, Michigan, and Texas. Iowa won back from Ohio the horse-judging trophy, and Kansas made the best record with swine. The corn-judging team from Iowa succeeded in maintaining its hold on the Cook bronze trophy, Kansas receiving second, and Missouri third.

A new form of intercollegiate competition was inaugurated by the *Chicago Daily Live Stock World*, which offered \$300 in 20 cash prizes for reports by students of the various sections of the exposition. The best showing was made by the Iowa men, who won first and second for cattle, first and fourth for swine, first, second, and third for horses, and fourth for sheep.

One of the most noteworthy features of the exposition was its international aspect. King Edward and Lord Rothschild were among the competitors in the horse-breeding section. Sheep were entered from England, and Canada sent cattle, horses, sheep, and swine. In the crowd of spectators were visitors from England, Scotland, and the Argentine Republic, and the agricultural departments of Nova Scotia, Quebec, Ontario, and Hawaii were officially represented. The announcement was made by the German consul that after careful investigation he had advised his government to enter exhibits in the future.

Progress on New Department Building.—The report of the building committee on the new laboratories for this Department states that the work has progressed, with the exception of the interior finish, to approximately the fourth-floor line, and it is expected that without unforeseen complications the buildings will be completed within the contract time, November 14, 1907. Within the 3½ years that have elapsed since the act authorizing the construction of the new quarters was approved, there has been an increase in the rented space occupied

by the Department of over 99 per cent, and an increase in the annual rentals of 150 per cent.

Measures before Congress.—A bill has been introduced into Congress by Senator Nelson and Representative Davis to increase the annual appropriation to agricultural colleges. The bill provides an increase of \$5,000 to each college for the year ending June 30, 1908, increasing this amount \$5,000 each year for 5 years, when a maximum annual appropriation of \$25,000, in addition to the Morrill Fund, will be reached. A portion of the appropriation may be used "for providing courses for the special preparation of instructors for teaching the elements of agriculture and the mechanic arts."

Other bills recently introduced into Congress include the following: A joint resolution to provide for the printing of 50,000 copies each of the Special Report on the Diseases of the Horse, and of the Special Report on the Diseases of Cattle; to appropriate \$50,000 additional for demonstration farms in the cotton boll-weevil district; appropriating \$250,000 to eradicate the Texas fever tick; for the establishment of a drainage fund and the construction of works for the reclamation of swamp and overflowed lands, and for the maintenance of agricultural colleges in Congressional districts. The urgent deficiency bill as passed contains an appropriation of \$250,000 to enable the Secretary of Agriculture to enforce the provisions of the pure-food law enacted at the last session.

Conference on Secondary Education in the South.—At a conference recently held at the University of Virginia, participated in by representatives from Southern State universities and colleges, superintendents of education, and other invited educators, a session of 4 hours was given to the discussion of agriculture in high schools, at which addresses were given by Dr. S. A. Knapp, of Louisiana; D. J. Crosby, of this Office; Prof. William Lochhead, of Macdonald College, and others. It seemed to be the consensus of opinion that all over the South there is an increasing demand for instruction in agriculture in schools of different grades, but that it is not now feasible to introduce it into all schools on account of the lack of competent teachers. It was agreed, however, that every effort should be made to take advantage of conditions which seem favorable for its introduction.

Virginia Educational Conference.—At a conference of superintendents, school officials, the State Teachers' Association, and the Virginia Library Association, held at Richmond, A. C. True read a paper on Agriculture in the Public Schools; A. M. Soule, of the Virginia Station, presented a report on The Virginia Farmer and the Schools, and D. J. Crosby gave an illustrated lecture on How Agriculture is Taught in the Public Schools.

New Veterinary College and Physiological Laboratory.—*The Breeders' Gazette* states that substantial progress has been made toward establishing a veterinary college at the Chicago Union Stock Yards as a department of the University of Illinois. A proposition to this effect has been submitted to the trustees of the university and has met with favorable consideration. The object of this institution will be, in addition to the training of ordinary veterinary practitioners, the supplying of inspectors for the Government service. In connection with the veterinary instruction the project contemplates completely equipped laboratory for physiological research. It is understood that the packing houses propose to contribute liberally toward the erection of buildings and the initial endowment, but that the management will rest entirely with the University of Illinois.

Downton College Closed.—The College of Agriculture at Downton, England, according to a recent note in *Mark Lane Express*, has been closed. This college was a private institution, opened in 1880 by Professor Wrightson, and was quite

successful until the outbreak of the Boer War in 1899, when, owing to the enlistment of many of the students, the enrollment was reduced to about 17. Since the close of the war the number of students has increased, but not sufficiently to warrant keeping up the school.

Domestic Training College in Scotland.—The opening of what is said to be the first Scottish domestic training college at Dunfermline is noted in the *Epicure* for November. Bonnyton House, Dunfermline, has been leased for the purpose. The instruction will include both outdoor and indoor work. The outdoor training is to embrace gardening, beekeeping, dairy work, and poultry rearing, while that indoors will include cookery, laundering, house and table work, dressmaking, and household management.

Agriculture Introduced at the Technical High School at Prague.—A recent number of the *Deutsche Landwirtschaftliche Presse* states that an agricultural department, offering a four-year course, has been established at the Royal Imperial Bohemian Technical High School at Prague. Prof. Julius Stoklasa has been elected dean of the department of agriculture, as well as of the department of "culture-technic." The studies to be taken up this year are higher mathematics, physics and mechanics, organic and inorganic chemistry, anatomy and physiology of plants, economic botany, general and economic zoology, mineralogy and geology, agricultural bacteriology, general biology, and rural economics, including practicums in the chemical and plant laboratories.

Agricultural Work at Birmingham University.—A department of economic zoology has been organized under the direction of W. E. Collinge. *Mark Lane Express* states that this is to be a "consultative department and bureau of information and experimental work," and that it is the first instance in which a university in Great Britain has offered farmers an opportunity for such free information.

Agriculture in Great Britain.—A report of a special agricultural committee, appointed by the tariff commission to examine the probable effect of a high-tariff system on agriculture, shows some striking changes in agricultural conditions in Great Britain. The wheat production, which in 1841-1845 was reported as sufficient for 90 per cent of the population, now supplies only 10.6 per cent. The area cultivated to grain crops has decreased 40 per cent in thirty years. Home-fed meats, representing 85 per cent of the total supply thirty years ago, now furnish but 55 per cent. On the other hand, dairy produce shows an increase of 140 per cent, and now forms the chief branch of agriculture in England.

"Agriculture in almost every branch shows a great decline, despite a very large increase in the population and a consequent increase in the demands for agricultural produce." This condition of affairs is attributed to a greater relative increase in local and imperial taxation on land, transport conditions, and the inability of the board of agriculture to aid the British farmer as his foreign competitors are aided.

Irrigation in New South Wales.—The *Scottish Geographical Magazine* reports some particulars of a great irrigation scheme which the New South Wales government proposes to carry out in the Murrumbidgee Valley and the Lachlan, Namoi, and Gwydor basins. The first step which it is proposed to undertake is the construction of a dam across the Murrumbidgee, thereby forming a reservoir to contain $1\frac{1}{2}$ times as much water as Sydney Harbor, and but little inferior to the great Nile dam. The full capacity of the reservoir will be 33,380,864,000 cu. ft., and the cost is estimated at about four million dollars. The catchwater area is 5,000 square miles. The water will be brought to the land to be irrigated entirely by gravitation, so that pumping will be unnecessary.

Miscellaneous.—The board of agricultural studies at Cambridge University has appointed Major P. G. Craigie, whose resignation as secretary of the British

Board of Agriculture and Fisheries was recently announced, to be Gilbey lecturer on the history of economics in agriculture.

The *Deutsche Landwirtschaftliche Presse* reports the death of Prof. Albrecht Konrad Thaer, of Giessen, on November 14, 1906. He was born in 1828 at Lüdersdorf, in the province of Brandenburg, and was a nephew of the renowned "father of rational agriculture." In 1860 he was appointed professor of agriculture at the University of Berlin. From 1871 until his retirement in 1901 he was director of the agricultural institute, laboratory and experiment field at Giessen.

W. R. Buttenshaw, a scientific assistant in the imperial department of agriculture for the British West Indies, has accepted an appointment as botanist in the agricultural department of India.

A recent number of the *Deutsche Landwirtschaftliche Presse* states that von Arnim-Criewen will succeed von Podbielski as State minister and minister of agriculture, domains, and forestry of Prussia.

A. C. Seward, well known for his research into the structure and affinities of fossil plants, has been appointed to fill the vacancy in the professorship of botany at Cambridge, occasioned by the death of Marshall Ward.

A recent issue of *Science* states that Dr. M. T. Cook has resigned his position as chief of the department of plant pathology of the Central Agricultural Experiment Station of Cuba, and expects to devote several months to studies at the New York Botanical Garden.

The Harvard Graduate School of Applied Science, which was established last spring, announces degree courses in landscape architecture and forestry. A bachelor's degree is required for admission to this school, and provision will be made for original work.

Armstrong College is the recipient of a legacy which will eventually amount to \$225,000. A portion of this fund must be used for increased compensation of the instructor in agriculture.

The agricultural school at Cawnpore is now in process of development into a college, and will henceforth have a three-year course, instead of a two-year course, as formerly. A number of residences for members of the faculty have recently been erected, and plans for the extension of other buildings are under consideration.

EXPERIMENT STATION RECORD.

Editor: E. W. ALLEN, Ph. D., *Assistant Director.*

EDITORIAL DEPARTMENTS.

Meteorology, Soils, and Fertilizers—W. H. BEAL.
Agricultural Botany and Vegetable Pathology—W. H. EVANS, Ph. D.
Field Crops—J. I. SCHULTE.
Horticulture and Forestry—C. B. SMITH.
Zootechny and Human Nutrition—C. F. LANGWORTHY, Ph. D.
Agrotechny, Dairy Farming, and Dairying—H. W. LAWSON.
Agricultural Chemistry—W. H. BEAL, C. F. LANGWORTHY, and H. W. LAWSON.
Economic Zoology, Entomology, and Veterinary Medicine—E. V. WILCOX, Ph. D.
Rural Engineering—B. P. FLEMING.
Rural Economics—J. B. MORMAN.
Agricultural Education—D. J. CROSBY.

CONTENTS OF VOL. XVIII, NO. 6.

Editorial notes:	Page.
Some problems in agricultural instruction.....	501
The training of teachers for agricultural instruction.....	503
Department of nutrition in the Carnegie Institution.....	505
Problems of Animal Nutrition, Henry Prentiss Armsby, Ph. D.....	508
Recent work in agricultural science.....	522
Notes	597

SUBJECT LIST OF ABSTRACTS.

AGRICULTURAL CHEMISTRY.

Quantitative volatilization of phosphoric acid, Jannasch and Heimann.....	522
Woy method for determination of phosphoric acid, Van Kampen.....	522
Rendering combinations of phosphoric and silicic acids soluble, Newton.....	522
Availability of phosphoric acid of the soil, Fraps.....	522
Determination of nitric acid in soils, Gutzeit.....	522
Determination of humus acids in soils by Tacke method, Van Daalen.....	522
Determination of small quantities of iron, Marriott and Wolf.....	523
Determining the crude fiber content of cocoa, Ludwig.....	523
Estimation of crude fiber in cocoa goods, Matthes and Müller.....	523
Determining the digestible protein in feeding stuffs, Stutzer.....	523
Estimating pepsin-soluble constituents of feeding stuffs, Stutzer et al.....	523
Estimating cellulose, lignin, and kutin in crude fiber, König.....	524
Optical rotation of gliadin in certain organic solvents, Mathewson.....	524
Quantitative estimation of albumen by precipitin reaction, Schulz.....	524
Fermentation changes in Muscovado sugars, Watts and Tempany.....	524

MAR 1 1907

	Page.
Estimation of cocoanut oil in butter fat, Harris.....	524
Detection of cocoanut oil in butter, Lührig.....	524
Extraction of fat from feces and occurrence of lecithin, Long.....	525
Gravimetric estimation of saltpeter in meat, Paal and Mehrrens.....	525
Examination of maple products, The lead value, Sy.....	525
Quantitative estimation of ergot in flour, Bernhart.....	525
Practical guide for food chemists, Pellerin.....	525
Yearbook of chemistry, Meyer et al.....	525

METEOROLOGY—WATER.

Monthly Weather Review, Vol. XXXIV, Nos. 7, 8.....	525
Climatology of Porto Rico from 1867 to 1905, Alexander.....	526
Climatological atlas of India, Eliot.....	526
The effect of the sea upon climate.....	527
Sunrise, moisture, and growth, Rawson.....	527
Results of meteorological observations, 1905, Heinrich et al.....	527
Swedish meteorological observations, 1905, Hamberg.....	527
Meteorology.....	528
Hourly meteorological and magnetic observations, Manila observatory.....	528
Precipitation in the North German river basins, Hellmann.....	528
Cirrus clouds and rain.....	529
The Mount Rose weather observatory, Church, jr.....	529
Water supply and sewerage.....	529
Use of copper in purification of water, Rettger and Endicott.....	530
Sulphate of iron and caustic lime in water purification, Ellms.....	530
Water softening and treatment, Booth.....	530

SOILS—FERTILIZERS.

Agricultural charts at the Congress of Applied Chemistry, Rome, 1906.....	531
Relation between soils and rocks from which derived, Milch.....	531
Oxidation in soils and productiveness, Darbishire and Russell.....	531
Phospho-humic compounds of the soil, Dumont.....	531
Soils of second steppe, Alway.....	531
Agricultural value of cacao soils of St. Thomas, Hébert.....	532
Soils of the middle buntersandstein, Blanck.....	532
Management of soils to conserve moisture, Failyer.....	532
Soil differences, Bonsteel.....	532
Loew's theory regarding the lime-magnesia ratio, de Ruijter de Wildt.....	532
Removal of black alkali by leaching, Cameron and Patten.....	532
Decrease of soil temperature in Prologh Mountains, von Kerner.....	533
Carbon bisulphid, its action on lower plant organisms, Heinze.....	533
Utility of earthworms in agriculture, de Ribaucourt and Combault.....	533
Some contributions to microbiology of soils, Heinze.....	533
Conditions affecting legume inoculation, Kellerman and Robinson.....	533
Experiments with nitrogen-assimilating bacteria, Bruttini.....	534
New nitrogen bacteria with autotrophic habits of life, Kaserer.....	534
Assimilation of nitrogen by Azotobacter and Radiobacter, Stoklasa.....	534
The fixation of atmospheric nitrogen.....	535
Synthesis of nitric acid at ordinary temperature, Berthelot.....	535
Industrial utilization of nitrogen of the air, Fuschini.....	535
Electrical production of nitric acid from air, Grandeau.....	536
Oxidation of nitrogen by silent discharges, Warburg and Leithäuser.....	536
Nitric acid and other spark reactions.....	536
A domestic supply of nitrogen, Caro.....	536
Nitrogen lime, its use and action.....	536
Apparatus for preparation of lime nitrogen and ammonium sulphate.....	536
The making of sulphate of ammonia.....	536
Treatment of vinasse and molasses for nitrogenous matter, Vasseux.....	536
Practical value of lime nitrogen as a fertilizer, von Knierim.....	536
Experiments with a cyanamid compound, Shutt and Charlton.....	537
Fertilizer experiments in 1905 with calcium cyanamid, Caruso.....	537
Decomposition of calcium cyanamid, Perotti.....	537
Nitrogen of green manures in light sandy soils, von SéeIhorst.....	538

	Page.
Field experiments with phosphatic and nitrogenous fertilizers, Grandeaun	538
Norwegian nitrate and the culture of corn, Grandeaun	538
Nitrite and nitrate as a top-dressing for corn, Grandeaun	538
Influence of fertilizing with straw on yield, von Seelhorst	538
Results of several years' field experiments with fertilizers, Tacke	539
Use of fertilizers with reference to soil analysis, Bock et al	539
Relative value of different phosphates, Prianski, aikov	539
Stability of Thomas-phosphate-ammonium-lime, Schmoeger	539
Behavior of bone and mineral superphosphate in soils, Montanari	539
Basic slag	539
Merits of phosphate, potash, and nitrogen on a fine sandy loam, Hersey	539
Use of leucitic rocks as fertilizer, Monaco	540
Utilization of potash minerals for fertilizing purposes, Plock and Mehner	540
Potash salts	540
Peat and marl deposits of Rederang and Moorsee basins, Steusloff	540
Composition and utility of fertilizing materials, Davidson and Ellett	540
Analyses of commercial fertilizers and Paris green, Halligen	540

AGRICULTURAL BOTANY.

The sexuality of cotton, Balls	540
Mechanism of carbon assimilation in green plants, Usher and Priestley	540
Variations in chlorophyll assimilation, Lubimenko	541
Temperature and toxic action, Brooks	542
Effect of soil sterilization on development of plants, Schulze	542
Studies on lignin and cellulose of wood, Spaulding	543
Cyanogenesis in plants, Leather	544
Cyanogenic glycosids of plants and utilization of reserve nitrogen, Soave	544
Occurrence of prussic acid and its derivatives in plants, Henry	544
A study of leguminous tubercles, Stefan	545
Influence of oligodynamic actions on radiclecola, Perotti	545

FIELD CROPS.

Guide to plant culture, Fischer	545
Report of school of agriculture farm, 1905, Cartwright	546
Alfalfa as a forage crop for Pennsylvania, Watson	546
The A B C of corn culture, Holden	546
Score card for dent corn	546
Cotton, its production, consumption, and economic importance, Pupin	546
The selection of cotton seed, Foaden	546
Experiments with oats, Duggar	547

HORTICULTURE.

Relation of winter apples to hardiness of trees, Macoun	548
Further experiments in the cool storage of fruit, Quinn	548
Fertilizing forced strawberries, von Brehmer	549
Date varieties and date culture in Tunis, Kearney	549
Resistant vineyards. Grafting, planting, cultivation, Bioletti	549
Manurial experiments with cacao in Dominica	549
Report of inspector of cocoanut plantations for year 1905, Brown	550

FORESTRY.

Indian trees, Brandis	550
Forests as accumulators of nitrogen, Henry	550
Fertilizer experiments in forest nurseries, Schalk	550
Farm wind-breaks and shelter-belts, Green	551
Notes on rubber producing plants, Harris	551

DISEASES OF PLANTS.

Notes on plant pathology, Delacroix	551
Fungoid pests of cultivated plants, Cooke	551
Cereal smuts and their propagation, Johnson	552

	Page.
Oat smut and its prevention, Appel and Gassner.....	552
Physiology of the parasite of sore shin of cotton, Balls.....	552
"Black root" disease of cotton, Smith and Lewis.....	552
A new alfalfa disease, Paddock.....	553
Potato leaf curl.....	553
Soil treatment of tobacco plant beds, Selby.....	554
Diseased apples and melons from the Cape of Good Hope, Massee.....	554
Pear rust, Güssow.....	554
Development and prevention of gray rot of grapes, Guillon.....	554
Some diseases of palms, Butler.....	555
A new disease of cultivated veronicas.....	555

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Revision of the skunks of the genus <i>Spilogale</i> , Howell.....	555
Monthly bulletin of the division of zoology, Surface.....	556
Entomological section, Howard.....	556
Expedition for study of plant pathology in Kamerun and Togo, Busse.....	556
List of publications of the Bureau of Entomology, Mabel Colecord.....	556
The slender seed-corn ground-beetle, Webster.....	556
<i>Lila ocellatella</i> on sugar beets, Giard.....	556
The potato moth, French.....	557
Thrips or black fly, Froggatt.....	557
The melon aphid, Chittenden.....	557
Spraying to control the San José scale, Smith.....	557
Soluble oils as destroyers of San José scale, Gossard.....	557
Insect pests affecting fruit trees, Lounsbury.....	557
A plague of <i>Macroductylus mexicanus</i> in the valley of Mexico, Inda.....	557
Caterpillar plagues, Herrera.....	558
Caterpillar pest of indigo in Behar, Lefroy.....	558
Red slug caterpillar; a serious pest of the tea plant, Mann.....	558
Production of golden pupae with <i>Vanessa urtica</i> and <i>V. io</i> , Mensik.....	558
Coloring matter of oak leaves and silk of <i>Saturnia gamma-mai</i> , Gantier.....	558
Eggs of <i>Samia cecropia</i> , <i>Pulvinaria innumerabilis</i> , and <i>Culex pipiens</i> , Davis.....	558
<i>Camnula pellucida</i>	558
A scale insect of the coconut palm, Flentiaux.....	558
The large larch sawfly (<i>Nematus erichsoni</i>), Macdougall.....	559
The maple leaf-stem borer or sawfly, Britton.....	559
Constriction of twigs by the bag worm, von Schrenk.....	559
The recently introduced dung fly parasite, Kotinsky.....	559
The British woodlice, Webb and Sillem.....	559
Ants, Kuauer.....	559
The ant, Escherich.....	559
Harvest mites, or "chiggers," Chittenden.....	559
Destruction of mosquitoes in houses with pyrethrum, Herrera.....	560
Contributions to the study of silkworms, Toyama.....	560
The length of the tongue of bees, Kulagin.....	560
The respiratory organs of bees, Dyachenko.....	560
The swarming of bees, Diatschenko.....	560
The number of bees in a colony, Devauchelle.....	560
Water for bees, Beulme.....	561
Evaporation from hives at night, Maujean.....	561
Artificial comb foundation, Pincof.....	561
Bacteria of the apiary, with special reference to bee diseases, White.....	561
